(March 22, 2024)

Abstract

Dynamics of FitzHugh-Nagumo (FN) neuron ensembles with time-delayed couplings subject to white noises, has been studied by using both direct simulations and a semi-analytical augmented moment method (AMM) which has been proposed in a preceding paper [H. Hasegawa, Phys. Rev E **xx**, yyyy (2004)]. For N -unit FN neuron ensembles, AMM transforms original $2N$ -dimensional stochastic delay differential equations (SDDEs) to finite-dimensional deterministic DEs for means and correlation functions of local and global variables. Finite-order recursive DEs are terminated at the n -th level in the level- m AMM (AMM $_m$), yielding $8(m+1)$ -dimensional deterministic DEs. When a single spike is applied, the oscillation may be induced when parameters of coupling strength, delay, noise intensity and/or ensemble size are appropriate. Effects of these parameters on the emergence of the oscillation and on the synchronization in FN neuron ensembles have been studied. The synchronization shows the fluctuation-induced enhancement at the transition between non-oscillating and oscillating states. Results calculated by AMM $_5$ are in fairly good agreement with those obtained by direct simulations.

I. INTRODUCTION

There have been many studies on effects of noises in dynamical systems with delays. Complex behavior due to noise and delay is found in many systems such as biological systems, signal transmissions, electrical circuits and lasers. Systems with both noises and delay are commonly described by stochastic delay differential equations (SDDEs). In recent years, linear SDDEs of Langevin equation are beginning to gain much attention [1]–[6]. The parameter range for the stationary solutions of the Langevin equation has been examined with the use of the step by step method [1], the moment method [2] and the Fokker-Planck equation (FPE) method [3] [4].

When we pay our attention to living brains, various kinds of noises are reported to be ubiquitous. A study on noise effects has been one of major recent topics in neuronal systems. It has been shown that the response of neurons may be improved by background noises. The typical example is the stochastic resonance in which weak noises enhance the transmission of signals with the subthreshold level. The transmission delay is inherent because the speed of spikes propagating through axons is finite. Conduction velocity ranges from 20 to 60 m/s, leading to non-negligible transmission times from milliseconds to hundreds milliseconds. Although an importance of effects of delay has been not so recognized as that of noises, there is an increasing interest in the complex behavior of time delays, whose effects have been investigated by using integrate-and-fire (IF) [8]–[12], FitzHugh-Nagumo (FN) [13]–[15], Hindmarsh-Rose (HR) [16], and Hodgkin-Huxley (HH) models [10] [11] [17] [18]. Exposed behaviors due to time delays are the multistability and bifurcation leading to chaos.

There are two difficulties in studying combined effects of noise and delay in brains. One is that the system is usually described by nonlinear SDDEs, which are generally more difficult than linear SDDEs. Dynamics of individual neurons includes a variety of voltage dependent ionic channels which can be described by nonlinear DEs of Hodgkin-Huxley-type models, or of reduced neuron models such as IF, FN and HR models. The other difficulty is that a small cluster of cortex consists of thousands of similar neurons. For a study of dynamics of noisy neuron ensembles with time-delayed couplings, we have to solve high-dimensional nonlinear SDDEs, which have been studied by direct simulations (DSs) [19] [20] and by analytical methods like FPE [21]. Simulations for large-scale neuron ensembles have been made mostly by using IF, FN, HR and phase models. Since the time to simulate networks by conventional methods grows as N^2 with N , the size of the ensemble, it is rather difficult to simulate realistic neuron clusters. Although FPE is a powerful method in dealing with the stochastic DE, a simple FPE application to SDDE fails because of its non-Markovian property [3] [5].

In a preceding paper [22] (which is referred to as I hereafter), the present author has developed an augmented moment method (AMM) for SDDE, employing a semi-analytical dynamical mean-field approximation (DMA) theory [23] [24]. In I, AMM is applied to an ensemble described by the delay Langevin model, transforming the original N -dimensional SDDEs to finite-dimensional DEs which are terminated at finite level m in the level- m AMM (AMM $_m$). Model calculations in I with changing the level m have shown that calculated results converge at a fairly small m . Actually results obtained by AMM $_6$ are in good agreement with those by DSs for linear and nonlinear Langevin ensembles. It has been demonstrated in I that AMM may be a useful tool in discussing dynamics and

synchronization of ensembles described by SDDs.

It is the purpose of the present paper to apply AMM to FN neuron ensembles with time-delayed couplings. In the next Sec. II, we apply our AMM theory to nonlinear SDDs of N -unit FN neuron ensembles, in order to get the infinite-dimensional deterministic DEs for the correlation functions of local and global variables. Infinite-dimensional recursive DEs are terminated at the finite level m in AMM. In Sec. III we report model calculations, showing that results of our AMM are in good agreement with those of DSS. Section IV is devoted to conclusions and discussions.

II. FN NEURON ENSEMBLE

A. Adopted model and method

Dynamics of a neuron ensemble consisting of N -unit FN neurons ($N \gg 2$), is described by the $2N$ -dimensional nonlinear SDDs given by

$$\frac{dx_{1i}(t)}{dt} = F[x_{1i}(t)] - cx_{2i}(t) + \frac{1}{N-1} \sum_{j \neq i}^N w_{ij} G(x_{1j}(t - \tau_{ij})) + \xi_i(t) + I^{(e)}(t); \quad (1)$$

$$\frac{dx_{2i}(t)}{dt} = bx_{1i}(t) - dx_{2i}(t) + e; \quad (i = 1 \dots N) \quad (2)$$

where $F[x(t)] = kx(t)[x(t) - h][1 - x(t)]$, $k = 0.5$, $h = 0.1$, $b = 0.015$, $c = 1.0$, $d = 0.003$ and $e = 0$ [23] [25], and x_{1i} and x_{2i} denote the fast (voltage) and slow (recovery) variables, respectively. The third term in Eq. (1) stands for interactions with the uniform couplings of $w_{ij} = w$ and delay times of $\tau_{ij} = \tau$, and the sigmoid function $G(x)$ given by $G(x) = 1/(1 + \exp[-(x - \theta)/\Delta])$, and θ denoting the threshold and the width, respectively [26]. The all-to-all couplings have been widely employed in theoretical studies. The assumed constant delay may be justified in certain neural networks [27]. The fourth term of Eq. (1), $\xi_i(t)$, denotes the Gaussian white noise given by $\langle \xi_i(t) \rangle = 0$ and $\langle \xi_i(t) \xi_j(t^0) \rangle = \delta_{ij} \delta(t - t^0)$ where δ denotes the magnitudes of independent noises and the bracket $\langle \dots \rangle$ the stochastic average [28]. The last term in Eq. (1), $I^{(e)}(t)$, denotes an external input whose explicit form will be shown later [Eq. (31)].

We apply our AMM developed in I to FN neuron ensemble given by Eqs. (1) and (2), defining global variables for the ensemble given by

$$X_i(t) = \frac{1}{N} \sum_{i=1}^N x_i(t); \quad i = 1, 2; \quad (3)$$

and their averages by

$$\langle X_i(t) \rangle = \langle X_i(t^0) \rangle; \quad (4)$$

We define the correlation functions between local variables, given by

$$C_{ij}(t; t^0) = \frac{1}{N} \sum_{i=1}^N \langle x_i(t) x_i(t^0) \rangle; \quad i, j = 1, 2 \quad (5)$$

where $x_i(t) = x_i(t)$ (t). Similarly we define the correlation function between global variables, given by

$$; (t; t^0) = \langle X_i(t) X_j(t^0) \rangle; \quad (6)$$

$$= \frac{1}{N^2} \sum_i \sum_j \langle x_j(t) x_i(t^0) \rangle; \quad (7)$$

where $X_i(t) = X_i(t)$ (t). Conventional variances and covariances are given by Eqs. (5)-(7) with $t = t^0$, for which the symmetry relations: $_{1,2}(t;t) = _{2,1}(t;t)$ and $_{1,2}(t;t) = _{2,1}(t;t)$, are hold. It is noted that $; (t;t)$ ($; = 1; 2$) expresses the spatial average of fluctuations in local variables of x_i while $; (t;t)$ denotes fluctuations in global variables of X_i .

After our previous studies [22-24], we have assumed that the noise intensity is weak and that the distribution of state variables takes the Gaussian form concentrated near the means of $(_1; _2)$. The second assumption is justified from numerical calculations for single FN [29,30] and HH neurons [31,32]. We will obtain infinite-order equations of motions for means, variance and covariances defined by Eqs. (5)-(7). They will be terminated at the level m in AMM. Readers who are not interested in mathematical details, may skip to Sec. III.

B. Equations of motions

After some manipulations, we get DEs for (t) , $; (t;t)$ and $; (t;t)$ ($; = 1; 2$) given by (for details see appendix A)

$$\frac{d _1(t)}{dt} = f_0(t) + f_2(t) _{1,1}(t;t) - c_2(t) + w u_0(t) + I^{(e)}(t); \quad (8)$$

$$\frac{d _2(t)}{dt} = b_1(t) - d_2(t) + e; \quad (9)$$

$$\frac{d _{1,1}(t;t)}{dt} = 2[a(t) _{1,1}(t;t) - c_{1,2}(t;t)] + 2w u_1(t) _{1,1}(t;t) + ^2; \quad (10)$$

$$\frac{d _{2,2}(t;t)}{dt} = 2[b_{1,2}(t;t) - d_{2,2}(t;t)]; \quad (11)$$

$$\frac{d _{1,2}(t;t)}{dt} = b_{1,1}(t;t) + [a(t) - d] _{1,2}(t;t) - c_{2,2}(t;t) + w u_1(t) _{2,1}(t;t); \quad (12)$$

$$\frac{d _{1,1}(t;t)}{dt} = 2[a(t) _{1,1}(t;t) - c_{1,2}(t;t)] + 2w u_1(t) _{1,1}(t;t) + \frac{^2}{N}; \quad (13)$$

$$\frac{d _{2,2}(t;t)}{dt} = 2[b_{1,2}(t;t) - d_{2,2}(t;t)]; \quad (14)$$

$$\frac{d _{1,2}(t;t)}{dt} = b_{1,1}(t;t) + [a(t) - d] _{1,2}(t;t) - c_{2,2}(t;t) + w u_1(t) _{2,1}(t;t); \quad (15)$$

with

$$a(t) = f_1(t) + 3f_3(t) _{1,1}(t;t); \quad (16)$$

$$u_0(t) = g_0(t) + g_2(t) _{1,1}(t;t); \quad (17)$$

$$u_1(t) = g_1(t) + 3g_3(t) - 1_{1,1}(t; t); \quad (18)$$

$$; (t; t^0) = \frac{1}{N-1} [N - 1_{1,1}(t; t^0) - 1_{2,1}(t; t^0)]; \quad (19)$$

where $f_1(t) = (1-\delta(t))F^{(1)}(1(t))$ and $g_1(t) = (1-\delta(t))G^{(1)}(1(t))$. Equations (8)–(15) include the higher-order terms of $1_{1,1}(t; t)$ and $1_{2,1}(t; t)$, whose equations of motions are given by (m = 1)

$$\begin{aligned} \frac{d 1_{1,1}(t; t - m)}{dt} = & [a(t) + a(t - m)] 1_{1,1}(t; t - m) - c[1_{1,2}(t; t - m) + 1_{2,1}(t; t - m)] \\ & + w[u_1(t - m) 1_{1,1}(t; t - m) \\ & + u_1(t - (m+1)) 1_{1,1}(t; t - (m+1))] + \delta_2(m); \end{aligned} \quad (20)$$

$$\frac{d 1_{2,2}(t; t - m)}{dt} = b[1_{1,2}(t; t - m) + 1_{2,1}(t; t - m)] - 2d 1_{2,2}(t; t - m); \quad (21)$$

$$\begin{aligned} \frac{d 1_{1,2}(t; t - m)}{dt} = & b 1_{1,1}(t; t - m) + [a(t) - d] 1_{1,2}(t; t - m) - c 1_{2,2}(t; t - m) \\ & + w u_1(t - m) 1_{1,2}(t; t - m); \end{aligned} \quad (22)$$

$$\begin{aligned} \frac{d 1_{2,1}(t; t - m)}{dt} = & b 1_{1,1}(t; t - m) + [a(t - m) - d] 1_{2,1}(t; t - m) - c 1_{2,2}(t; t - m) \\ & + w u_1(t - (m+1)) 1_{2,1}(t; t - (m+1)); \end{aligned} \quad (23)$$

$$\begin{aligned} \frac{d 1_{1,1}(t; t - m)}{dt} = & [a(t) + a(t - m)] 1_{1,1}(t; t - m) - c[1_{1,2}(t; t - m) + 1_{2,1}(t; t - m)] \\ & + w[u_1(t - m) 1_{1,1}(t; t - m) \\ & + u_1(t - (m+1)) 1_{1,1}(t; t - (m+1))] + \frac{\delta_2!}{N}(m); \end{aligned} \quad (24)$$

$$\frac{d 1_{2,2}(t; t - m)}{dt} = b[1_{1,2}(t; t - m) + 1_{2,1}(t; t - m)] - 2d 1_{2,2}(t; t - m); \quad (25)$$

$$\begin{aligned} \frac{d 1_{1,2}(t; t - m)}{dt} = & b 1_{1,1}(t; t - m) + [a(t) - d] 1_{1,2}(t; t - m) - c 1_{2,2}(t; t - m) \\ & + w u_1(t - m) 1_{1,2}(t; t - m); \end{aligned} \quad (26)$$

$$\begin{aligned} \frac{d 1_{2,1}(t; t - m)}{dt} = & b 1_{1,1}(t; t - m) + [a(t - m) - d] 1_{2,1}(t; t - m) - c 1_{2,2}(t; t - m) \\ & + w u_1(t - (m+1)) 1_{2,1}(t; t - (m+1)); \end{aligned} \quad (27)$$

where $\delta(x) = 1$ for $x = 0$ and 0 otherwise.

C. Summary of our method

The original two-dimensional SDDE given by Eqs. (1) and (2) are transformed to infinite-dimensional deterministic DDEs given by Eqs. (8)–(15) and (20)–(27), which are due to non-Markovian property of SDDE. It is, however, impossible to simultaneously solve these infinite-order recursive equations. We will adopt the level-m AMM (AMM_m) in which the recursive DDEs are terminated at the finite level m, as

$$; (t; t_{(m+1)}) = ; (t; t_m); \quad (28)$$

$$; (t; t_{(m+1)}) = ; (t; t_{(m+1)}); \quad (29)$$

$$g_1(t_{(m+1)}) = g_1(t_m); \quad (30)$$

leading to $8(m+1)$ -dimensional DES. In the following Sec. III, we will examine AMM $_m$, performing calculations with changing m , in order to show that AMM $_5$ may yield results in fairly good agreement with those of DS [Fig. 5(b)]. In the limit of $\tau = 0$, Eqs. (20)–(27) reduce to Eqs. (10)–(15), then Eqs. (8)–(15) agree with Eqs. (20)–(27) in Ref. [23] for FN neuron ensembles without delays [26].

Model calculations will be reported in the following Sec. III. DSs have been performed for 2N DES given by Eqs. (1) and (2) by using the fourth-order Runge-Kutta method with a time step of 0.01. Initial values of variables at $t_2 \in [-\tau; 0]$ are $x_i(t) = y_i(t) = 0$ for $i = 1$ to N . DS results are the average of 100 trials otherwise noticed. AMM calculations have been performed for Eqs. (8)–(30) by using also the fourth-order Runge-Kutta method with a time step of 0.01. Initial values are $x_1(t) = x_2(t) = 0$ at $t_2 \in [-\tau; 0]$, and $y_1(t; t^0) = y_2(t; t^0) = 0$ at $t_2 \in [-\tau; 0]$ or $t_2^0 \in [-\tau; 0]$ ($t = t^0$). All calculated quantities are dimensionless.

III. MODEL CALCULATIONS

A. Effects of coupling (w) and delay (τ)

In this study, we pay our attention to the response of the FN neuron ensembles to a single spike input of $I^{(e)}(t)$ given by [23]

$$I^{(e)}(t) = A \delta(t - t_{in}) \delta(t_{in} + T_w - t); \quad (31)$$

where $\delta(x) = 1$ for $x > 0$ and 0 otherwise, A stands for the magnitude, t_{in} the input time and T_w the spike width. We have adopted the same parameters of $A = 0.10$, $t_{in} = 100$ and $T_w = 10$ as in Ref. [23]. Parameter values of w , τ , and N will be explained shortly.

When an input spike given by Eq. (31) is applied, the oscillation may be triggered when model parameters are appropriate. The w -phase diagram showing the oscillating (OSC) and non-oscillating (NOSC) states is depicted in Fig. 1, which is calculated for $\tau = 0$ and $N = 10$. In the case of $\tau = 0.01$, for example, the OSC region is slightly shrunk compared to that for $\tau = 0$, as will be shortly discussed [Figs. 5(a) and 5(b)]. The w -phase is separated by two boundaries in positive- and negative- w regions. Circles in Fig. 1 express pairs of w and τ adopted for calculations to be shown in Figs. 2 and 3. A long the horizontal, dashed line in Fig. 1, the w value is continuously changed in calculations to be shown in Figs. 4(a) and 4(b).

In order to monitor the emergence of the oscillation, we calculate the quantity:

$$O = \overline{O(t)} = \frac{1}{t_2 - t_1} \int_{t_1}^{t_2} dt O(t); \quad (32)$$

with

$$O(t) = \frac{1}{N} \sum_i [\langle x_i(t)^2 \rangle - \langle x_i(t) \rangle^2]; \quad (33)$$

$$= \langle x(t)^2 \rangle - \langle x(t) \rangle^2 + \frac{1}{N} \sum_i \langle x_i(t) \rangle^2; \quad (34)$$

which becomes finite in the oscillation state but vanishes in the non-oscillating state, the overline denoting the temporal average between t_1 ($= 2000$) and t_2 ($= 4000$).

The synchrony within ensembles is measured by [22] [23]

$$s = \overline{S(t)}; \quad (35)$$

with

$$S(t) = \frac{N_{i,j}(t;t) - i_{i,j}(t;t)}{N - 1}; \quad (36)$$

which is 0 and 1 for completely asynchronous and synchronous states, respectively.

We have calculated time courses of $i_1(t)$, $i_{j,1}(t;t)$, $i_{j,1}(t;t)$ and $S(t)$, whose results are depicted in Figs. 2(a)-2(l), solid and dashed curves denoting results of AMM and DS, respectively.

For $\tau = 0$, an output spike of $i_1(t)$ res after an applied input which is plotted at the bottom of Fig. 2(a) [and also of 2(e) and 2(i)]. It is noted that state variables are randomized when an input spike is applied at $t = 100$ because independent noises have been added since $t = 0$. Figures 2(b) and 2(c) show $i_{j,1}$ and $i_{j,1}$ for $\tau = 0$, respectively. The synchronization ratio $S(t)$ for $\tau = 0$ shown in Fig. 2(d) has an appreciable magnitude: its maximum values calculated in AMM are 0.038 and 0.077 at $t = 107$ and 123, respectively. Figure 2(e) shows that when a delay of $\tau = 20$ is introduced, an input signal leads to a spike output with an additional, small peak in i_1 at $t = 133$. Figures 2(f) and 2(g) show that although a peak of $i_{j,1}$ for $\tau = 20$ becomes larger than that for $\tau = 0$, a peak of $i_{j,1}$ is decreased by an introduced delay. Maximum values of $S(t)$ calculated by AMM are 0.154 and 0.130 at $t = 126$ and 140, respectively, for $\tau = 20$. We note from Fig. 2(i) that for a larger $\tau = 60$, an input spike triggers an autonomous oscillation with a period of about 65. Peaks in $i_{j,1}$, $i_{j,1}$ and S are progressively increased with increasing t as shown in Figs. 2(j), 2(k) and 2(l): peaks of $i_{j,1}$, $i_{j,1}$ and S saturate at $t > 1200$ with the values of 0.00253, 0.00014 and 0.098, respectively, in AMM calculations. We note in Figs. 2(a)-2(l) that results of i_1 obtained by AMM and DS are indistinguishable, and that AMM results of $i_{j,1}$, $i_{j,1}$ and S are in fairly good agreement with those of DSs.

Figure 1 shows that although the obtained NO SC \rightarrow SC phase is nearly symmetric with respect to the $w = 0$ axis, it is not in the strict sense. Actually the property of the oscillation for inhibitory couplings ($w < 0$) is different from that for excitatory couplings ($w > 0$). Figures 3(a) and 3(b) show autonomous oscillations for $w = 0.1$ and $w = -0.1$, respectively, with $\tau = 60$, $\tau = 0.01$ and $N = 10$. The period of the oscillation T is given by $T = \tau + \tau_i$ where τ_i denotes the intrinsic delay for rings. For inhibitory feedback with negative w , FN neurons re with the rebound process, which requires a larger τ_i for ring than for excitatory feedback with positive w . Then the period of $T = 86$ for autonomous oscillation with the negative w becomes larger than that of $T = 65$ with the positive w .

By changing the w value along the horizontal, dashed line in Fig. 1, we have calculated the w dependence of ϕ_0 and s , whose results are plotted in Figs. 4(a) and 4(b), respectively, for $\tau = 0.0001$ and 0.01. The oscillation emerges for $w > 0.058$ or $w < -0.063$ with $\tau = 0.0001$, while with $\tau = 0.01$ it occurs for $w > 0.060$ or $w < -0.070$. The transition from NO SC to O SC states is of the first order because ϕ_0 is abruptly increased at the critical

coupling of $w = w_c$, where s has a narrow peak. In contrast, the relevant NO SC-OSC transition in the nonlinear Langevin model is of the second order [22].

We have investigated, in more detail, the w dependence of ϕ_0 and s near the transition region of $0.05 < w < 0.07$, which is sandwiched by vertical, dashed lines in Figs. 4(a) and 4(b), results for $\sigma = 0.0001$ and $\sigma = 0.01$ being plotted in Figs. 5(a) and 5(b), respectively. Figure 5(a) shows that the critical w value for the NO SC-OSC transition is $w_c = 0.0579$ for $\sigma = 0.0001$ both in DS and AMM 5. When we adopt AMM 1, we get the result showing the NO SC-OSC transition at $w = 0.6$, although we cannot get solutions for $0.0586 < w < 0.060$. With the use of AMM 2, we get the transition at $w = 0.058$, though solutions are not obtainable for $0.0580 < w < 0.0582$. We have noted that AMM m converges at the level $m = 3$, above which calculated results are almost identical. Figure 5(b) shows that the critical value of w_c for $\sigma = 0.01$ is 0.0600 in DS and 0.0607 in AMM 5. For $m = 1, 2$ and 3, the NO SC-OSC transition occurs at $w = 0.0644, 0.0609$ and 0.0807 , respectively: w_c for $m = 3$ approaches that for $m = 5$ (in what follows results of AMM 5 will be reported). It is interesting to note in Figs. 5(a) and 5(b) that the synchrony s shows fluctuation-induced enhancement at the NO SC-OSC transition. This is due to an increase in the ratio of $\phi_{1,1}(t; t) = \phi_{1,1}(t; t)$ in Eq. (36) although both $\phi_{1,1}(t; t)$ and $\phi_{1,1}(t; t)$ are increased at the NO SC-OSC transition. Similar phenomenon has been reported in the nonlinear Langevin model [22] and in heterogeneous systems in which the oscillation emerges when the degree of the heterogeneity exceeds the critical value [33] [34].

B. Effects of noise (σ)

Comparing Fig. 5(b) with Fig. 5(a), we note that when the noise intensity is increased from $\sigma = 0.0001$ to $\sigma = 0.01$, the critical w_c value for the NO SC-OSC transition is increased: $w_c = 0.0579$ (0.0579) for $\sigma = 0.0001$ and $w_c = 0.0600$ (0.0607) for $\sigma = 0.01$ in DS (AMM). Figure 6(a) shows the dependence of ϕ_0 and s for $\sigma = 60, w = 0.06$ and $N = 10$. ϕ_0 is rapidly decreased at w_c where s has a broad peak: w_c is about 0.01 in DS while it is about 0.0075 in AMM. Figure 6(b) shows that the similar dependence of ϕ_0 and s is obtained also for a larger $w = 0.062$, for which $w_c = 0.015$ in DS and $w_c = 0.014$ in AMM. A suppression of the oscillation by noises is realized in the Langevin model [22] and in some calculations for systems with heterogeneity [34], although the noise-induced oscillation is reported in Refs. [21] [35] [36]. In particular, Zorzano and Vazquez [21] (ZV) showed the noise-induced oscillation in FN neuron ensembles ($N = 1$) with time delays by using FPE method. The difference between ZV's results and ours may be due to the difference in the adopted FN model and/or ensemble size. In order to get some insight on this issue, we have performed AMM calculations for our FN model with larger ensemble sizes of $N = 100$ and 1000, and obtained again a suppression of the oscillation by noises [37]. It is not clear for us how ZV took into account the non-Markovian property of SDD within their FPE method [3] [5].

C. Effects of size (N)

The N dependence of ϕ_o and ϕ_s for $\tau = 0.01$, $w = 0.06$ and $\beta = 60$ is shown in Fig. 7 where open circles (squares) express ϕ_o (ϕ_s) in DS, and where thin (bold) solid curves denote ϕ_o (ϕ_s) in AMM. It is shown that with increasing the size of ensemble, ϕ_o is gradually increased at $N = N_c$ where ϕ_s has a broad peak, the critical dimension being $N_c = 10$ in DS and $N_c = 100$ in AMM. Results of our AMM calculations are qualitatively similar to those of DS although calculated N_c values are different between the two methods.

IV. CONCLUSIONS AND DISCUSSIONS

In Sec. II, we have obtained the infinite-dimensional ordinary differential equations. It is, however, possible to get expressions given by partial differential equations (PDEs) if we define the correlation functions:

$$C_i(t; z) = \frac{1}{N} \sum_i \langle x_i(t) x_i(t-z) \rangle; \quad (37)$$

$$D_i(t; z) = \langle X_i(t) X_i(t-z) \rangle; \quad (38)$$

introducing a new variable z [see Eqs. (5) and (6)]. For example, PDEs for $C_{1,1}(t; z)$ are given by

$$\begin{aligned} \frac{\partial C_{1,1}(t; 0)}{\partial t} &= 2[aC_{1,1}(t; 0) - cC_{1,2}(t; 0)] + 2w u_1(t) E_{1,1}(t) + \dots; \quad (39) \\ \frac{\partial}{\partial t} + \frac{\partial}{\partial z} C_{1,1}(t; z) &= aC_{1,1}(t; z) - cC_{1,2}(t; z) \\ &\quad + w u_1(t) E_{1,1}(t; z); \quad \text{for } z > 0 \quad (40) \end{aligned}$$

where $E_{1,1}(t; z) = [ND_{1,1}(t; z) - C_{1,1}(t; z)]/[N - 1]$. It is noted that Eqs. (39) and (40) correspond to Eqs. (10) and (20), respectively. Then we have to solve PDEs including (t) , $C_i(t; z)$ and $D_i(t; z)$ with a proper boundary condition in the $(t; z)$ space. A similar PDE approach has been adopted in Ref. [6] for an analysis of the stationary solution of the linear Langevin equation with delays. In an earlier stage of this study, we pursued the PDE approach. We realized, however, from the point of computer programming that the use of the ordinary DEs given in AMM is more tractable than that of PDEs.

Our calculations have shown that FN neuron ensembles with delays exhibit the multistability when model parameters such as w , β , and N are varied. The multistability is the common property of the system with time delay. Actually the nonlinear Langevin ensembles discussed in I also show the multistability: the w phase diagram of FN ensembles shown in Fig. 1 is similar to that of the Langevin ensembles shown in Fig. 6 of I. In either case, fluctuation-induced synchronization is realized near the transition between OSC and NO SC states. These results imply that the oscillating, highly synchronous state may be realized in ensembles for smaller couplings with a proper delay than with no delays. This is consistent with the recent result of Ref. [38], where the importance of delays is stressed for the long-range synchronization with low coupling strength.

In summary, we have discussed dynamics of FN neuron ensembles with delays by using a semi-analytical method developed in I. Our method has a limitation of weak noises but it is free from the magnitude of delay times. This is complementary to the small-delay approximation [3], whose application to FN neuron ensembles with delays is discussed in appendix C. For FN ensembles to show the oscillation, we have to adopt an appreciable magnitude of delay ($\tau > 20$), for which SDA method cannot be employed. In this study we have discussed only the case of a single spike input. Our method may be, however, applicable to arbitrary inputs such as periodic spike trains and Poisson spikes, as was made for HH neuron ensembles (without delays) [24]. Although results calculated by our method are in fairly good agreement with those obtained by DC, the quantitative analytical theory is still lacking. In this study, we have assumed regular couplings ($w_{ij} = w$) and uniform time delays ($\tau_{ij} = \tau$). In real systems, however, couplings are neither regular nor random, and time delays are nonuniform with a variety of dendrite radius and length. It is interesting to include these properties by extending our approach, which is in progress and will be reported in a future paper.

APPENDIX A : DERIVATION OF EQS. (8)-(15)

We express Eqs. (1) and (2) in a Taylor expansion of $x_i (= x_{1i})$ and $y_i (= x_{2i})$ up to the third-order terms to get

$$\frac{dx_i(t)}{dt} = f_1(t) x_i(t) + f_2 [x_i(t)^2 \quad x_{1,1}(t; t)] + f_3(t) x_i(t)^3 + c y_i(t) + \bar{I}_i(t) + \bar{I}_i^{(c)}(t); \quad (A1)$$

$$\frac{dy_i(t)}{dt} = b x_i(t) - d y_i(t); \quad (A2)$$

with

$$\bar{I}_i^{(c)}(t) = w \sum_{j \in \mathcal{I}_i} \frac{g_1(t)}{N-1} x_j(t) + \frac{g_2(t)}{N-1} \sum_{j \in \mathcal{I}_i} [x_j(t)^2 \quad x_{1,1}(t; t)] + \frac{g_3(t)}{N-1} \sum_{j \in \mathcal{I}_i} x_j(t)^3; \quad (A3)$$

where $f_\alpha(t) = (1/N!) F^{(\alpha)}(x_1(t))$ and $g_\alpha(t) = (1/N!) G^{(\alpha)}(x_1(t))$. Averages of Eqs. (A1) and (A2) with Eqs. (3) and (4) yield DEs for means of $d_1=dt$ and $d_2=dt$ [Eq. (8)]. DEs for variances and covariances may be obtained by using the equations of motions of x_i and y_i . For example, DE for $d_{1,2}(t; t)=dt$ is given by

$$\frac{d_{1,2}(t; t)}{dt} = \frac{1}{N} \sum_i \left(\frac{dx_i(t)}{dt} y_i(t) + x_i(t) \frac{dy_i(t)}{dt} \right); \quad (A4)$$

which leads to Eq. (12). DEs for other variances and covariances are similarly obtained.

APPENDIX B: DERIVATION OF EQS. (20) AND (27)

In the process of calculations of Eqs. (8)-(15), we get new correlation functions given by

$$S_1(t_1; t_2) = \frac{1}{N} \sum_i \langle x_i(t_1) x_i(t_2) \rangle; \quad (B1)$$

$$S_2(t_1; t_2) = \frac{1}{N} \sum_i \langle y_i(t_1) y_i(t_2) \rangle; \quad (B2)$$

where $x_i = x_{1i}$, $y_i = x_{2i}$, $t_1 = t$ and $t_2 = t - \tau$, or $t_1 = t - \tau$ and $t_2 = t$. We will evaluate them by using DEs for $x_i(t)$ and $y_i(t)$, which are linearized from Eqs. (A1)-(A3):

$$\frac{d x_i(t)}{dt} = a(t) x_i(t) - c y_i(t) + \frac{w}{N} \sum_{j \neq i}^X g_1(t) x_j(t) + \xi_i(t); \quad (B3)$$

$$\frac{d y_i(t)}{dt} = b x_i(t) - d y_i(t); \quad (B4)$$

where $a(t) = f_1(t) + 3f_3(t - \tau)$. Neglecting the t dependence in $a(t)$, we get formal solutions of Eqs. (B3) and (B4) given by

$$x_i(t) = \frac{A + d}{A - B} \int_0^t ds \exp^{(t-s)A} \left[\frac{w}{N} \sum_{j \neq i}^X g_1(s) x_j(s) + \xi_i(s) \right] + \frac{B + d}{A - B} \int_0^t ds \exp^{(t-s)B} \left[\frac{w}{N} \sum_{j \neq i}^X g_1(s) x_j(s) + \xi_i(s) \right]; \quad (B5)$$

$$y_i(t) = \frac{b}{A - B} \int_0^t ds \exp^{(t-s)A} \left[\frac{w}{N} \sum_{j \neq i}^X g_1(s) x_j(s) + \xi_i(s) \right] + \frac{b}{A - B} \int_0^t ds \exp^{(t-s)B} \left[\frac{w}{N} \sum_{j \neq i}^X g_1(s) x_j(s) + \xi_i(s) \right]; \quad (B6)$$

where A and B are roots of the equation given by $z^2 - (a + d)z - ad + bc = 0$. By using the method of steps in Ref. [6], we obtain the step by step functions, from which we get

$$S_1(t; t - \tau) = S_1(t - \tau; t) = \frac{1}{2} \tau^2; \quad (B7)$$

$$S_2(t; t - \tau) = S_2(t - \tau; t) = 0; \quad (B8)$$

where $\tau(x) = 1$ for $x = 0$ and 0 otherwise. By using Eqs. (B7) and (B8), we get Eqs. (20)-(27). The assumption of a neglect of the t dependence in $a(t)$ may be justified, to some extent, from results calculated by our method which are in fairly good agreement with those by DS as reported in Sec. III.

APPENDIX C: THE SMALL-DELAY APPROXIMATION

When the delay τ is very small, we may adopt the small-delay approximation (SDA) proposed in Ref. [3]. With this approximation, we first transform the SDEs to stochastic

non-delayed DEs, and then to deterministic DEs with the use of DMA [23]. For a small τ , we may expand $x_{1i}(t - \tau)$ in Eq. (1) as

$$x_{1i}(t - \tau) \approx x_{1i}(t) - \tau \frac{dx_{1i}(t)}{dt}; \quad (C1)$$

with which Eq. (1) becomes stochastic non-delayed DEs given by

$$\begin{aligned} \frac{dx_{1i}(t)}{dt} + \frac{w}{N-1} \sum_{j \in \mathcal{I}_i}^X G^0(x_{1j}(t)) \frac{dx_{1j}(t)}{dt} \\ = F(x_{1i}) - cx_{i2} + \frac{w}{N-1} \sum_{j \in \mathcal{I}_i}^X G(x_{1j}(t)) + i(t) + I^{(e)}; \end{aligned} \quad (C2)$$

When we apply DMA to 2N-dimensional stochastic DEs given by Eqs. (2) and (C2), we get equations of motions for means, variances and covariances, given by

$$\frac{d \langle x_1(t) \rangle}{dt} = [1 - w u_1][f_0(t) + f_2(t) - c_2(t) + w g_0(t) + I^{(e)}(t)]; \quad (C3)$$

$$\frac{d \langle x_2(t) \rangle}{dt} = b_1(t) - d_2(t) + e; \quad (C4)$$

$$\begin{aligned} \frac{d \langle x_{11}(t; t) \rangle}{dt} = 2[a(t) - c_{12}(t) + w u_1(t)] + \frac{w u_1(t)}{N-1} \langle x_{11}(t; t) \rangle; \\ 2w u_1(t) a(t) - c_{12}(t) + \frac{w u_1(t)}{N-1} \langle x_{11}(t; t) \rangle; \end{aligned} \quad (C5)$$

$$\frac{d \langle x_{22}(t; t) \rangle}{dt} = 2[b_{12}(t) - d_{22}(t)]; \quad (C6)$$

$$\begin{aligned} \frac{d \langle x_{12}(t; t) \rangle}{dt} = b_{11}(t) - [a(t) - d_{12}(t) - c_{22}(t) + w u_1(t)] \\ w u_1(t) a(t) - c_{22}(t) + \frac{w u_1(t)}{N-1} \langle x_{12}(t; t) \rangle; \end{aligned} \quad (C7)$$

$$\frac{d \langle x_{11}(t; t) \rangle}{dt} = 2[1 - w u_1(t)] a(t) - c_{12}(t) + w u_1(t) \langle x_{11}(t; t) \rangle + \frac{2}{2N}; \quad (C8)$$

$$\frac{d \langle x_{22}(t; t) \rangle}{dt} = 2[b_{12}(t) - d_{22}(t)]; \quad (C9)$$

$$\begin{aligned} \frac{d \langle x_{12}(t; t) \rangle}{dt} = b_{11}(t) - [a(t) - d_{12}(t) - c_{22}(t) + w u_1(t)] \\ w u_1(t) a(t) - c_{22}(t) + w u_1(t) \langle x_{12}(t; t) \rangle; \end{aligned} \quad (C10)$$

where $a(t)$ and $b_{ij}(t; t)$ are given by Eqs. (16) and (19), respectively.

A numerical comparison between AMM and SDA is made in Fig. 8, where solid and chain curves denote results of AMM and SDA, respectively. For $\tau = 0$ both methods lead to the identical result. For small delays of $\tau = 1$ and 2, results of SDA are in fairly good agreement with those of AMM. As the delay is increased to $\tau > 5$, however, the discrepancy between the two methods becomes significant.

FIGURES

FIG. 1. The w - τ phase diagram showing the oscillating (OSC) and non-oscillating (NOSC) states for $\tau = 0$ and $N = 10$. For sets of parameters of w and τ marked by circles, time courses of $x_1(t)$, $x_2(t)$, $x_3(t)$ and $S(t)$ are calculated, whose results are shown in Figs. 2 and 3. Along the horizontal dashed line ($\tau = 60$), the w dependence of x_0 and x_s is calculated in Figs. 4 and 5.

FIG. 2. (color online). Time courses of $x_1(t)$, $x_{1,1}(t)$, $x_{1,2}(t)$ and $S(t)$ calculated by AMM theory (solid curves) and DS (dashed curves) with $A = 0.10$, $\tau = 0.01$, $w = 0.1$ and $N = 10$: (a) x_1 , (b) $x_{1,1}$, (c) $x_{1,2}$ and (d) S for $\tau = 0$, (e) x_1 , (f) $x_{1,1}$, (g) $x_{1,2}$ and (h) S for $\tau = 20$, and (i) x_1 , (j) $x_{1,1}$, (k) $x_{1,2}$ and (l) S for $\tau = 60$. Chain curves at bottom s of (a), (e) and (i) express input spikes.

FIG. 3. Time courses of $x_1(t)$ showing the oscillation for (a) $w = 0.1$ and (b) $w = 0.1$ with $\tau = 60$, $\tau = 0.01$ and $N = 10$ calculated by AMM, the result of (a) being shifted upwards by 2.

FIG. 4. The w dependence of (a) x_0 and (b) x_s for $\tau = 0.0001$ (solid curves) and $\tau = 0.01$ (dashed curves) with $\tau = 60$ and $N = 10$. The region sandwiched by dashed, vertical lines is enlarged in Figs. 5(a) and 5(b) for $\tau = 0.0001$ and 0.01 , respectively.

FIG. 5. The w dependence of x_0 and x_s for (a) $\tau = 0.0001$ and (b) $\tau = 0.01$ with $\tau = 60$ and $N = 10$. Thin and bold solid curves denote results of 10^{-4} and 10^{-2} , respectively, in AMM, whereas squares and circles express those of 10^{-4} and 10^{-2} , respectively, in DS. AMM results with different levelm ($m = 1, 2, 3$ and 5) are shown. Dotted lines are only for a guide of the eye (see text).

FIG. 6. The τ dependence of x_0 and x_s for (a) $w = 0.60$ and (b) $w = 0.62$ with $\tau = 60$ and $N = 10$. Thin and bold solid curves denote results of 10^{-4} and 10^{-2} , respectively, in AMM whereas squares and circles express those of 10^{-4} and 10^{-2} , respectively, in DS. Dotted lines are only for a guide of the eye.

FIG. 7. The N dependence of x_0 and x_s for $\tau = 0.01$, $\tau = 60$ and $w = 0.06$. Thin and bold solid curves denote results of 10^{-4} and 10^{-2} , respectively, in AMM, whereas squares and circles express those of 10^{-4} and 10^{-2} , respectively, in DS. Dotted lines are only for a guide of the eye.

FIG. 8. The time course of $x_1(t)$ calculated in AMM (solid curves) and in a small-delay approximation (SDA) (chain curves) with $\tau = 0.01$, $w = 0.1$ and $N = 10$ (see appendix C).
