(D ated: M arch 22, 2024)

The solid-solution $SrRu_{1 \times}Rh_{x}O_{3}$ (0 x 1) is a variable-electron-con guration system forming in the nearly-cubic-perovskite basis, ranging from the ferror agnetic $4d^{4}$ to the enhanced paramagnetic $4d^{5}$. Polycrystalline single-phase sam ples were obtained over the whole composition range by a high-pressure-heating technique, followed by measurements of magnetic susceptibility, magnetization, speci c heat, therm opower, and electrical resistivity. The ferror agnetic order in long range is gradually suppressed by the Rh substitution and vanishes at x 0:6. The electronic term of speci c-heat shows unusual behavior near the critical Rh concentration; the feature does not m atch even qualitatively with what was reported for the related perovskites (Sr,Ca)RuO₃. Furtherm ore, another anomaly in the speci c heat was observed at x 0:9.

I. IN TRODUCTION

Perovskite-ruthenium oxides and the single-structure family form a distinguished class of the 4d-band oxides that show rich electronic phenomena, such as unconventional superconductivity,^{1,2} a quantum critical transition,^{3,4,5,6,7} and negative spin polarization.⁸ These phenom ena are of great interest to the condensed m atter community, and thus, these materials have recently received much attention. In regards to the nearly cubic perovskite SrR uO₃, many e orts have focused on exploring its itinerant ferrom agnetism . The electrically conducting state of SrR uO₃ is probably dom inated by Ru-4d electrons and a sm all am ount of 0-2p holes,^{9,10} and is clearly a ected by the ferrom agnetic order (T_c 160 K).^{11,12,13,14,15} So far experimental studies on the material reveal strongly correlated features and substantial in uences of spin uctuations through m easurem ents of optical conductivity,¹⁶ far-infrared transmission,¹⁷ Ru-NMR,¹⁸ photoem ission spectra,¹⁹ m agneto-optical conductivity, r^{20} re ectivity, r^{21} m agnetization and resistivity of thin $\ln s_r^{22,23,24,25}$ and m easurem ents of the Hall coe cient.26 Those data clearly indicate that the perovskite SrR uO 3 goes beyond our understanding of normalmetals.

In a sharp contrast with previous reports, a highly pure single crystal of SrR uO₃, which was less in unceed by disorder, was found to show norm all characteristics within Ferm i-liquid theory.²⁷ This fact probably indicates that the electrically conducting state is highly sensitive to disorder as mentioned in the report. Regardless of the in uence of disorder, we were motivated to chemically dope ferrom agnetic SrR uO₃ over a wide range to explore a dramatic transition to a novel electronic state, as was offen achieved in this manner.

R ecently, the synthesis of SrR hO₃ was reported for the rst tim e^{28} T he R h oxide perovskite is structurally analogous to SrR uO₃, and is electrically conducting as well as SrR uO₃.²⁸ T he perovskite SrR hO₃ shows an enhanced

param agnetism 28,29 E ach Rh⁴⁺ (4d⁵) is coordinated by six oxygen atom s and is in the low -spin state due to the relatively large 10D q.³⁰ B ecause the state ($t_{2g}^5 e_g^0$) form s an S = 1/2 system, appearance of possible quantum characteristics could be expected for SrRhO₃ and closely related m aterials.³¹ W e then pursued a system atic substitution of Rh for Ru of the perovskite. A sa result, we have succeeded in obtaining polycrystalline sam ples over the full solid-solution range between SrRuO₃ and SrRhO₃, which establishes a new avenue for probing the itinerant ferrom agnetic state (4d⁴) from the param agnetic state (4d⁵).

In this paper, we report the m agnetic and the electrical transport properties of the nearly cubic perovskites $SrRu_{1 \times Rh_{x}O_{3}}$ (0 x 1), and compare the data to those of the related perovskites ($Sr_{,La}$) $RuO_{3}^{32,33}$ and ($Sr_{,Ca}$) $RuO_{3}^{14,15,34,35,36,37}$ As expected with increasing Rh concentration in $Sr(Ru_{,R}h)O_{3}$, the ferrom agnetic order is gradually suppressed and then nally disappears. The data clearly indicate that the electronic term of the speci c heat is correlated with the m agnetic character in an unusual fashion.

II. EXPERIMENTAL

Polycrystalline single-phase sam ples were prepared as follows. Fine and pure (>99.9%) powder of SrO₂,³⁸ RuO₂, RhO₂, Rh, and Ru were employed as starting materials, and appropriate am ounts were mixed into the stoichiom etry SrRu_{1 x} Rh_xO₃ (0 x 1 at 0.1 step). Each 0.4-g sam ple was placed into a platinum capsule and then heated at 1500{1600 C for 1 hr at 6 GPa in a highpressure finnace. The elevated tem perature was 1550 C for the x = 0.0 and 0.1 sam ples, 1500 C for the x = 0.2 to 0.8 sam ples, and 1600 C for the x = 0.9 and 1.0 sam ples. The applied pressure was held constant during the heating^{28,39} and m aintained until after the capsule was quenched to room tem perature. The polycrystalline sam ples were black in color and retained a pellet shape (approximately 6 mm in diameter and 2 mm in thickness). Each face of the sam ple pellet was polished carefully in order to remove any possible contam ination from chem ical reactions with the capsule.

A small piece of each product was investigated by standard x-ray (CuK) di raction at room temperature. Each x-ray pattern showed clearly a G dFeO 3-typepeak distribution and absence of signi cant im purities as well as that for the previous sample of SrRhO₃.²⁸ The set of x-ray patterns indicated the form ation of a full solid-solution range between $SrRuO_3$ (P bnm, a = 5.5670(1) A, b = 5.5304(1) A, c = 7.8446(2) A, and V = 241.5 A^3)⁴⁰ and SrRhO₃ (Pnm a, a = 5.5394(2) A, b = 7.8539(3) A, c = 5.5666(2) A, and V = 242.2 A^3).²⁸ The orthorhom bic-unit-cell volum e was calculated from the unit-cell param eters deduced from the x-ray data, and those are plotted versus composition in Fig1. A nom alies do not appear in the lattice-parameter plots, and the unit-cell volum e varies m ore or less m onotonically, indicating that the perovskite-solid solution is likely to preserve the orthorhom bic sym m etry over the full solidsolution range studied. The relatively small degree of variation of the param eters probably re ects mainly the smalldi erence in ionic radii (${}^{\rm I}{
m R}\,{
m h}^{4+}$ (0.60A) is com – parable in size to $^{VI}Ru^{4+}$ (0.62A)].⁴¹

E lectronic properties of the sam ples were investigated by various ways; m agnetic susceptibility, m agnetization, electrical resistivity, speci c heat, and them opower were studied. Each data set was collected on the sam e sam – ple batch. The m agnetic properties were studied in a com m ercial apparatus (Q uantum D esign, M PM S-X L system) between 2 K and 390 K below 70 kO e. The electrical resistivity was m easured in a com m ercial apparatus (Q uantum D esign, PPM S system) by a conventional acfour-term inal technique; the ac-gauge current at 30 H z was 1 m A for the x = 0 to 0.2 sam ples and 0.1 m A for the x = 0.3 to 1 sam ples. Prior to the electrical m easurem ents, each sam ple pellet was cut out into a bar shape, and each face was polished with alum inum -oxide-lapping

In in order to reduce the contact resistance, followed by deposition of gold pads (200 nm in thickness) at four locations along the bar. Silver epoxy was used to x ne platinum wires (30 m) at the each gold term inal. The contact resistance was less than 4 ohm s. Speci cheat m easurements were conducted on a small piece of each pellet ($10\{25 \text{ mg}\}$ in the PPM S system with a time-relaxation m ethod over the temperature range between 1.8 K and 10.3 K. The x = $0.9 \text{ sam plew asm easured up to 20 \text{ K}$ in the magnetic eld of 70 kO e. The magnetic-eld contribution to the background was found being smaller than 1% of the speci cheat data, and then carefully sub-tracted. Therm opower for all the sam ples was measured in the PPM S system between 5 K and 300 K with a com – parative technique using a constantan standard.

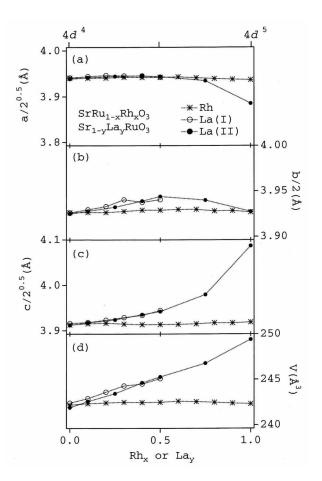

FIG. 1: Orthorhom bic unit-cell parameters (a(c) and the unit-cell volume (d) of the perovskites SrR u₁ $_x$ R h_xO₃ (stars) and Sr₁ $_y$ La $_y$ R uO₃ (open and led circles). The sets of data for Sr₁ $_y$ La $_y$ R uO₃ were taken from published reports.^{32,33}

III. RESULTS AND DISCUSSION

Lattice param eters and the volum e of the orthorhom bic unit cell of $SrRu_{1 x} Rh_{x}O_{3}$ are compared with those of the isoelectronic and isostructural (Sr,La)RuO₃ in Fig.1. The La data were quoted from two independent reports.^{32,33} As shown in the plots, the two sets of La data are entirely consistent with each other, and clearly reveal that the La substitution for Sr rem arkably changes the unit-cell size. In the La plots an anisotropic change of the unit-cell appears (approxim ately -1.4% along the a-axis, nearly zero along the b-axis, and 4.5% along the caxis), which might re ect a change in the Ru {O -bond distances as well as the degree of cooperative rotations of the RuO_6 octahedra.^{32,33} These features should result from a balance between two opposing factors in the GdFeO 3type basis: the ionic-size issue $[^{X II}La^{3+}$ (1.36A) is sm aller than $^{
m X\,II}
m Sr^{2+}$ (1.4 A)] and the charge neutrality ${}^{V}{}^{I}Ru^{3+}$ (0.68A) is larger than ${}^{V}{}^{I}Ru^{4+}$ (0.62A)].⁴¹

The unit-cell-size change observed in $(Sr,La)RuO_3$ is in sharp contrast to that of $Sr(Ru,Rh)O_3$, where a fairly small change occurs approximately 0.1% in the volume { a value com parable to the x-ray experim ental error. This fact probably provides an advantage for the present investigation, because the in uence of local-structure distortions is rem arkably reduced over the whole Rh concentration, as the relation of the distortion to the m agnetic order was frequently focused on as a signi cant issue in m any experim ental and theoretical studies.^{9,14,15,32,34,35,36,37}

The magnetic data for Sr(Ru,Rh)O₃ are presented in Figs2 and 3. First, we shall focus on the end member SrRuO₃ (x=0.0). Shown in the gures, the magnetic susceptibility curve (vs. T) shows a clear ferrom agnetic transition at 160 K and a spontaneous magnetic moment (P_{sp}) of 0.82 B per Ru at 5 K, in good agreement with previous work,^{11,12,13,14,15,42} indicating the quality of the present sample. The P_{sp} was estimated by means of a least-squares t to the magnetization data (Fig.3): A general empirical formula M = P_{sp} + aHⁿ was applied above approximately 10 kOe, where a and n were adjustable parameters.⁴³

In order to quantitatively analyze the change in the m agnetic susceptibility through the Rh substitution, the Curie-W eiss law was applied to the 1= vs T plots. The \mathbb{P}^2 , applied form ula was $1 = (T) = 3k_B (T)$ Ŋ⊥ w) where $k_{\rm B}$, N₀, P_e, and w are the Boltzm ann constant, A vogadro's constant, e ective B ohrm agneton, and W eiss tem perature, respectively. As represented on the x = 0.9plot, a least-squares t to the linear part (200 K Т 380 K) resulted in a fair evaluation of the Curie-W eiss param eters for all the sam ples except SrR hO₃, which is known not to follow the Curie-W eiss law.²⁸ The magnetic param eters of Sr(Ru,Rh)O₃ estim ated in this study are listed in Table I and plotted in Fig.4 to make a comparison with those of the isoelectronic system (Sr,La)RuO₃.

Shown in Fig.4c, the Weiss temperature of $Sr(Ru,Rh)O_3$ switches sign at x 0:6, accom panied by the disappearance of long-range ferrom agnetic order. This point (x 0.6) could be considered as a com positional critical point as was found for the related systems (Sr,Na,La)RuO $_3^{34}$ and (Sr,Ca)RuO $_3$.^{35,36,37} A small component of ferrom agnetic character persists beyond the critical point as seen in the susceptibility data for the x = 0.6(0.9 sam ples (Fig.2)), and it is likely due to a formation of local magnetic clusters, where Ru is rich in the perovskite host. A correlation of the transition temperature (T_c^0) of the small ferrom agnetic component with the Ru concentration supports this presumption (Fig.4a). Alternatively, a small amount of magnetic impurities may be responsible for the ferrom agnetic character. M ore will be said on this later.

Shown in Fig.4b, the e ective Bohr magneton of $Sr(Ru,Rh)O_3$ undergoes a relatively small change between the ideallim its of S = 1 for Ru^{4+} and 1/2 for Rh^{4+} over the whole range studied. However, for the sam ples above x = 0.6, the values of P_e are higher than the sim – ple expectation indicated by the broken curve. A sim ilar feature was also found in the La sam ples above y = 0.3. This observation suggests that the P_e enhancem ent is

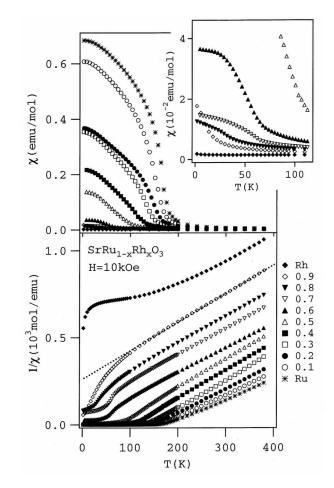

FIG.2: Tem perature dependence of the m agnetic susceptibility of the polycrystalline SrR $u_1 \times R h_x O_3$ at 10 kO e on cooling (vs. T, upper panel), and the data in another form (1= vs. T, lower panel). The sm all panel shows an expansion of the low-tem perature portion of the vs. T plots. The dotted line indicates a representative for t to the Curie-W eiss law.

likely induced by the ferro to param agnetic transition. In addition, an orbital contribution is possibly involved in the origin of the enhancem ent as discussed in the La substitution study.³³

As seen in Fig.4a and Fig.4c, the relatively quick suppression of the ferrom agnetic order in $(Sr,La)RuO_3$ occurs more slowly in the less distorted $Sr(Ru,Rh)O_3$. For example, $SrRu_{0:6}Rh_{0:4}O_3$ shows ferrom agnetic order $(T_c 100 \text{ K})$, while $Sr_{0:6}La_{0:4}RuO_3$ does not, although both are at the same doping level $(d^{4:4})$. Comparison between the isoelectronic and isostructural perovskites indicates that the G dFeO₃-type distortion substantially in uences the ferrom agnetic order as found in $(Sr_Na_{,La})RuO_3$.

At the $4d^5$ end, i.e. SrRhO₃, a band-structurecalculation study predicts that a hypothetical cubic SrRhO₃ is likely to have a ferrom agnetically spinpolarized ground state, in which the distortions are ideally free.^{31,44} This is in accord with a logical extension

^bthe is unable to be estimated.

 $^{\rm C} {\rm SrR}\,hO_3$ does not follow the Curie-W eiss law (Ref. 28). Previously, 7.6 m J m ol¹ K² was reported for of SrRhO₃ (Ref. 28). The disagreem ent possibly results from either an improvement of the sample quality (higher purity starting materials) or the choice of the tem perature range to t. The D ebye tem perature previously reported was miscalculated (Refs. 28 and 39). The correct calculations com e within approximately a 70-K width, largely depending on the choice of the tem perature range; 324{399 K and 316{362 K for $_{\rm D}$ of SrRhO₃ and Sr₃Rh₂O₇, respectively.

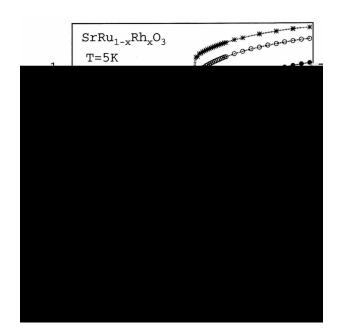

FIG. 3: Applied magnetic eld dependence of the magnetization of the polycrystalline $SrRu_1 \times Rh_x O_3$ at 5 K. Each symbol indicates every third points measured for each sam ple.

of the above consideration. The prediction was tested on sam ples of $(Sr,Ca)RhO_3$ and $(Sr,Ba)RhO_3$, since the degree of distortions in these sam ples was system atically m odi ed. Unfortunately, the expected m agnetic order in long range has not been found thus far.²⁹

E lectronic transport properties were measured on the polycrystalline $Sr(Ru,Rh)O_3$ samples; electrical resistiv-

ity, therm opower, and speci c-heat data are shown in Figs.5{7, respectively. The data for $Sr(Ru,Rh)O_3$ indicate that the resistivity has a large composition dependence, as more than 6 orders of magnitude change are observed from the metallic to sem iconducting state (as shown in Fig.5). The end member, SrRuO₃, has a fairly m etallic character with a kink at 160 K , in good agreem ent with previous reports.^{22,27,34,45} The m etallic character gradually transform s to sem iconductor-like with increasing R h concentration up to x = 0.6, and then the resistive character reverts back to being m etallic for further Rh substitution. A though the whole resistivity data are probably som ewhat com plicated by the polycrystalline nature of samples, including resistive grain boundaries, the rem arkably large dependence on com position re ects mainly a disorder e ect related to the distribution of Rh and Ru at the perovskite B-site. This is strongly suggested by the resistive character becoming larger at approxim ately the center of the com position range. In order to investigate the probable disorder e ect further, the resistivity data at x = 0.6 were plotted into two independent forms as shown in the top panel in Fig.5. As expected, the data follow closely to a variable-range- $T^{1=4}$), much hopping form (logarithm ic resistivity m ore than the alternative form (T^{1}) , which suggests the disorder e ect is predom inant in the sem iconducting state.

A lthough the electrical character of $Sr(Ru,Rh)O_3$ varies trem endously, the therm celectric property is rather featureless (Fig.6). All the Seebeck data are consistent with a low-carrier density metallic system, and the positive Seebeck coe cient indicates that the major-

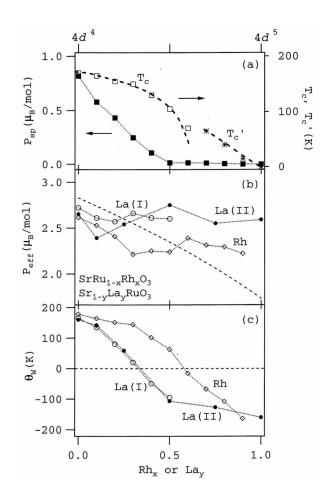

FIG.4: Sum m ary of m agnetic parameters of SrRu_{1 x} R h_xO₃ deduced from the experimental data, and comparison with those of the isoelectronic Sn y LayRuO₃^{32,33}; (a) Curie tem – perature T_c, transition temperature of the sm all component T_c⁰, and spontaneous magnetic m om ent P_{sp} m easured at 5 K for SrRu_{1 x} R h_xO₃. P_{sp} for La sam ples were not provided in the reports.^{32,33} (b) E ective Bohr m agneton P_e per m ole. The broken curve indicates an interm ediate m agnetic m om ent per mode. The broken curve indicates an interm ediate magnetic m om ent per equivalent of the form ula P_{cal} = $\frac{1}{(1 - x)P_{s=1}^2 + xP_{s=1=2}^2}$, where P_s = $2^{p} \frac{S(S + 1)}{S(S + 1)}$ B. (c) W eiss temperature w.

ity carrier is holelike. It is known that the them opower is more sensitive than resistivity to changes in the electronic structure of materials. Why the resistivity (varying by 6 orders of magnitude) is so sensitive to chem ical disorder and the therm opower is not is unclear. How – ever, for the samples above the critical concentration (x 0:6), the therm opower remains relatively linear in temperature above 100 K, in good accord with freeelectron di usion therm opower of metals. For samples below x = 0.6, the therm opower tends to saturate at high temperatures. Nonlinearity in the di usion therm opower, as like those, is often observed in materials containing transition metals.⁴⁶

The speci c-heat data (Fig.7) were attempted to be analyzed by two independent parameters (electronic-

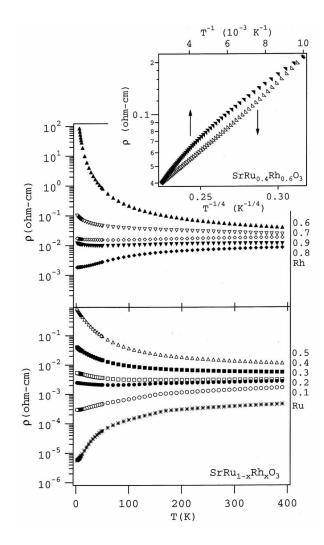

FIG.5: Tem perature dependence of the electrical resistivity of the polycrystalline $SrRu_{1 \ x} Rh_{x}O_{3}$. The data for x = 0.0{0.5 sam ples are shown in the lower panel, and the others are in the upper panel. Top panel: com parison between two types of plots of the electrical resistivity data at x = 0.6.

speci c-heat coe cient) and $_{\rm D}$ (D ebye tem perature) in the low-tem perature lim it (T $_{\rm D}$). The analytic formula employed here was

$$\frac{C_{v}}{T} = + \frac{12^{4}}{5} n N_{0} k_{B} - \frac{1}{3}_{D} T^{2}; \qquad (1)$$

where r was the num ber of atom sper form ula unit. Since a magnetic contribution is expected to appear in addition to the two terms in Eq.1, this attempt is therefore prelim inary.^{47,48} How ever, we expected the attempt for a valuable achievement as was done in many speci-cheat studies on magnetic materials. The di erence between C_p and C_v was assumed insignicant in the temperature range studied. The values of and $_D$ for the sam ples of Sr(Ru,Rh)O₃ were then obtained by a least-squares method with the linear part (C_p =T vs. T²) between 30 K² and 100 K² (5.4 K < T < 10 K). The parameters are

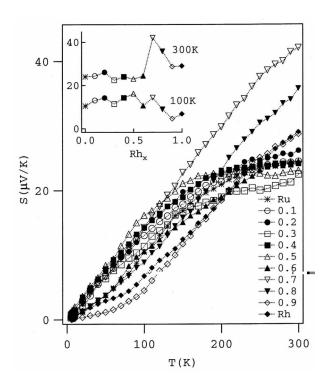

FIG. 6: Therm celectric power of the polycrystalline $SrRu_1 \times Rh_xO_3$. Two sets of data at 100 K and 300 K are compared in the inset.

plotted versus Rh concentration in the small panel of Fig.7. It should be noted that the points for the x = 0.9 sam ple are missing, because its surprising nonlinear speci c heat did not allow them to be extracted from the data in the usualway (the up turn was reproducibly observed).

From the t, we nd 28 mJ mbl K² for = SrR uO₃, which is in good agreem ent with the established data range from $29{36 \text{ mJ} \text{ mol}}$ K², while the Debye tem perature ($_{\rm D}$ = 412 K) is slightly higher than the reported values by approxim ately 20 to 40 K $.^{19,26,36,37,49,50}$ This small discrepancy may result from trace chemical in purities contained in the present sample of SrR uO 3 or the sample is slightly o stoichiom etry, which can occur at the extrem e heating conditions. A lternatively, a possible magnetic contribution might in uence the t to the data som ew hat because there are no magnetic term s in Eq.1, if the high-pressure heating varied slightly the degree of local-structure distortions which are sensitive to the magnetism .9

The curve in the sm all panel of F ig.7 shows a rather complicated feature, while the D ebye-tem perature curve shows a simple V shape re ecting the lattice change. The value reaches a minimum at x 0:6, where the long-

range m agnetic order disappears, and become s increasingly prominent at x 0.9. This is also the concentration where the Curie-W eiss-type paramagnetism (1= T) transforms to the unconventional type (1= T^2).²⁸ These results suggest that is likely being coupled to

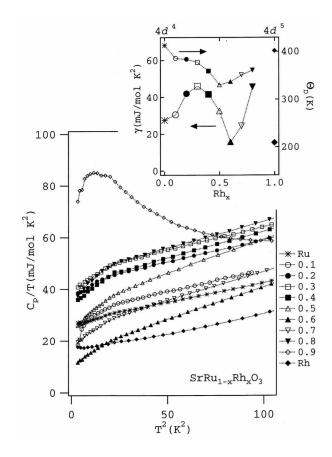

FIG.7: Speci c heat of the polycrystalline SrR u_{1 x} R h_xO₃. The data are plotted in the C_p=T vs. T² form . Dotted curves are guides to the eye. Fit to the linear parts by the form ula (Eq.1) yields electronic speci c-heat coe cient () and D e-bye tem perature ($_D$) in prelim inary sense, those are plotted versus the R h concentration in the sm all panel.

the magnetic properties of the series.

Through the present investigation of Sr(Ru,Rh)O3, we measured a variety of properties of the polycrystalline samples, and found the speci c-heat data were perhaps the most intriguing. The speci c-heat data for $SrRu_{1 x}Rh_{x}O_{3}$ clearly imply that a magnetic factor is substantial in the origin of the anomalous feature. W e then investigated the feature of the closely related system $(Sr_{,C}a)RuO_{3}$ to make a comparison with the present data: We found that the phenom enology of the curve for $(Sr_{r}Ca)RuO_{3}$ does not match at all with that for Sr(Ru,Rh)O₃.⁵¹ An enhancement of the vicinity of the compositional critical point was more commonly observed for the ferrom agnetic systems, including Y (Co,A l) $_2$, 52 Lu (Co,A l) $_2$, 53 and N iCu alloys, 54 rather than the decrease of . A possible picture invoking the variation of the density of states at the Ferm i level is unlikely to account for the suppression in Sr(Ru,Rh)O₃, because the degree of structural variation is rather sm all (Fig.1). A band-lling picture does not seem adequate, either.44 The most likely picture for the decrease is due to a random ness e ect. As suggested

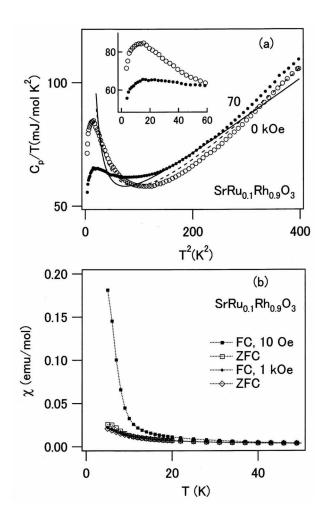

FIG. 8: (a) Speci c heat of $SrRu_{0:1}Rh_{0:9}O_3$ m easured in the m agnetic eld 70 kO e (solid circles). The inset shows an expansion of the low tem perature portion. Attempts to t the probable m agnetic contribution were m ade with the zero-eld data (open circles). The data above the peak temperature is unlikely to follow either an empirical form (dotted curve) or a form including a Schottky term (solid curve). D etails are in the text. (b) Temperature dependence of the m agnetic susceptibility at the low elds, 10 O e and 1 kO e, on heating to 300 K after cooling the sam ple without an applied m agnetic eld (zero eld cooling, ZFC) and then on cooling in the eld (eld cooling, FC).

by the electrical resistivity study, the B-site random ness plays a signi cant role in the electronic system of the solid-solution $Sr(Ru,Rh)O_3$. The in the system decreases probably due to an in uence of the disorder as well as decreasing of the electrical conductivity. It is, how ever, still noteworthy that the remains large (m ore than 15 m J m ol K^2), although the electrical resistivity is rather large (m ore than 100 ohm cm). Currently, we have not yet reached a clear conclusion on how gets suppressed at the ferrom agnetic critical point, how – ever, the data suggest that the random ness contribution is likely essential in the origin. Further studies focused on the possible association between the random ness and the magnetic order would be of interest.

The anomaly in the speci c heat of the x = 0.9 sam ple is also probably magnetic in origin, and in order to investigate this feature, three possible form swere tested by a least-squares m ethod; (1) The Schottky term "= T^3 , where "was an adjustable factor, was added linearly to Eq.1.^{52,54} (2) Empirical magnetic terms = T and (3) $T^{2} \log T$, where and were adjustable factors, were attempted as well.^{52,54} Accordingly, none of the three attempts produced a good t to the data; The curves providing the best ts are shown in Fig.8a. The curve for (3) was not shown because the parameters were unphysical. The fact that the regular form s do not satisfy the x = 0.9 data (Fig.8a) suggests unconventional magnetism.³¹ A corresponding peak was not observed in $(Sr,Ca)RuO_3$, ^{36,37} so the origin of the anomaly in the x = 0.9 data is, therefore, of interest.

The speci c heat of the x = 0.9 sample was reinvestigated in magnetic eld. The measurement was conducted at 70 kOe, and the data were plotted with the zero-eld data in Fig.8a. As shown, the peak is clearly suppressed and the linear part slightly shifts in parallel. These facts clearly indicate the manifest peak at x = 0.9 results from a magnetic origin, and the linear part includes magnetic contributions in addition to the regular electronic term. The analytic form ula in Eq.1 is therefore insu cient to clarify the speci c heat data of $SrRu_{1} \times Rh_{x}O_{3}$; magnetic terms should be appended to Eq.1 for a more rigorous analysis. Furthermore, an expected peak shift in the magnetic eld, if spin-glass or magnetic-cluster glass contribution is signi cant, is not clearly seen (inset in Fig.8a).55 The eld-induced suppression suggests a spin- uctuations contribution, however an attempt to t to the Cp data by the analytical formula for spin-uctuations was not at all successful; it was worse than the previous case (the curve to t is not shown).28

In order to investigate the x = 0.9 sam ple further, low - ekd-m agnetic susceptibility was measured; the data are presented in Fig.8b. Them on agnetic hysteresis was clearly observed at 10 0 e below about 20 K, suggesting a magnetically glassy character. The glassy feature may be due to freezing of ferrom agnetic clusters, as suggested by the high- eld susceptibility data (Fig.2), or a possible spin-glass transition. The data above, unfortunately, did not provide a su cient inform ation to identify the origin of the peculiarities of C_p at x = 0.9. Further m easurem ents will be needed to clarify the nature of the characteristic peak.

In sum m ary, we have investigated the electronic transport and m agnetic properties of the full-range-solid solution $SrRu_1 \ _x Rh_x O_3 \ (0 \ x \ 1)$, which is a variable-electron con guration system from $4d^4$ to $4d^5$ on the perovsk ite-structure basis. We found that the behavior for $SrRu_1 \ _x Rh_x O_3$ does not m atch even qualitatively with that for the intim ately related $(Sr,Ca)RuO_3$. The substitution random ness probably contributes significantly to the decrease around the com positional criti-

calpoint (x 0:6), which unavoidably prevents us from studying a true magnetic contribution to the feature. M eanwhile, the data suggest that magnetic contributions play a central role in the speci c heat in the vicinity of x = 0.9. Possible form ation of Ru-rich magnetic clusters in the perovskite host may be responsible for the observations, however the features of C_p were not fully explained by the model abone. The unconventional magnetism of SrRhO₃ is also possibly associated with the peculiarities of C_p at x = 0.9. Further experimental studies, as well as theoretical considerations, would be signi cant in expanding our insight into the ferrom agnetism of Sr(Ru,Rh)O₃.

- ³⁸ SrO₂ was prepared as follows. SrC ½-6H₂O was dissolved in 300 ml of water, followed by dropwise of ammonia

solution and H_2O_2 solution. The precipitation was washed with water after litered, and then dried in oxygen for 3 hours, resulting in white powder. Therm ogravim etric and x-ray di raction analysis characterized the powder to be SrO₂.
