# Inelastically scattering particles and wealth distribution in an open econom y 

Frantisek Slanina<br>Institute of Physics, A cadem y of Sciences of the C zech Republic, N a Slovance 2, C Z-18221 P raha, C zech Republic

#### Abstract

U sing the analogy w ith inelastic granular gasses we introduce a model for wealth exchange in society. T he dynam ics is govemed by a kinetic equation, which allow s for self-sim ilar solutions. T he scaling function has a power-law tail, the exponent being given by a transcendental equation. In the lim it of continuous trading, closed form of the wealth distribution is calculated analytically.

PACS num bers: 89.65.-s, $05.40 . \mathrm{a}, 02.50 .-\mathrm{r}$

## I. IN TRODUCTION

The distribution of wealth am ong individuals $w$ ithin a society was one of the rst \natural law s" of econom ics [1]. Indeed, its study was m otivated by the desire to bring the accuracy attributed to naturalsciences, nam ely physics, to econom ic sciences. The celebrated $P$ areto law states that the higher end of the wealth distribution follows a power-law P (W) W ${ }^{1}$ with exponent robust in time.

The validity of the $P$ areto law was questioned and reexam ined $m$ any tim es but the core $m$ essage, stating that the tail of the distribution is a power law rem ains in force. T here are recent investigations, e. g. [2, 3, [4, 5], giving reasonable em pirical evidence for it. In fact, it is not so $\mathrm{m} u$ ch the functional form itself but its spatial and tem poral stability that is intriguing. Indeed, while the value of the exponent $m$ ay slightly vary from one society to another, the very fact of the power-law 0 .tail in the distribution is valid alm ost everyw here. Recent investigations suggest that the range of validity of the $P$ areto law $m$ ay extend as far in the past as to the ancient Egypt of the $P$ haraohs [6].

The universality of the power-law tail is surely a phenom enon asking for explanation. Recently, there was a lot ofe ort establishing nally the multiplicative random processes repelled from zero as a $m$ athem atical source of the pow er-law distributions [1, [8, [1, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20]. A ltematively, the killed m ultiplicative processes as sources of pow er-law s w ere studied in [4]. H ow ever, there are plenty of possible ways how the multiplicative random processes of this type com e onto scene. O ne of the $m$ ost studied im plem entations were the generalized Lotka-V olterra equations [10, 11, 12, 13] and the analogy w ith directed polym ers in random me dia [21, 22, 23]. B oth of these schem es are form alized by a kinetic equation describing the exchange of wealth betw een agents and global redistribution of w ealth which plays the role of repelling from zero. R elated approaches were subsequently pursued by a num ber of studies and sim ulations $24,25,26,27,28,29,30,31,32,33,34,35$,

E lectronic address: slanina@ fzu.cz
$36,37,38,39,40]$.
$M$ ore recently, em pirical studies of the lower end of the wealth axis showed that the distribution of wealth is rather exponential than pow er-law, while the high-w ealth tail still rem ains power-law [3, 41, 42]. This nding was interpreted as a result of a conservation law for total w ealth, leading to the robust B oltzm ann-like exponential distribution, whatever the random wealth exchange be, in full analogy w ith the energy distribution in a gas of elastically scattering $m$ olecules.

This, togetherw ith older studies w ithin the sam e spirit [43], lead to the view of econom ic activity as a scattering process of agents, analogous to inelastically scattering particles 29, 30, 31, 44, 45, 46, 47]. Indeed, the inelasticity is indispensable to explain the pow er-law tail and it is also reasonable to suppose that the totalw ealth increases on average.

The num erical sim ulations perform ed to date con $m$ the em ergence of pow er-law tail in agent-scattering processes w ith great reliability. H ow ever, analytic insight is lacking in $m$ ost of the studies available today. T he $m$ ain concem of our work is to 11 this gap, providing analytical results at least for a sim pli ed m odel of wealth exchange. To com ply w th the task we w ill be guided by existing analytical approaches for $m$ odels of inelastically scattering particles.

Inelastic scattering of particles w as studied thoroughly in the context of granular $m$ aterials [48]. T he sim plest one of the m odels used is the M axw ell m odel, whose inelastic variant w as investigated in detail [49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61]. M ore realistic m odels of granular gasses were also introduced [62, 63] but their full account goes beyond the topic of this work. Them ost im portant conclusion of these studies is that a self-sim ilar solution of the kinetic equations exist, which is not stationary in tim e, but assum es tim e-independent form after proper rescaling of the energy. The tail of the scaling function becom es pow er-law under certain condition.

The form alism developed for granular gases can be readily adapted forbinary w ealth exchange of agents. Indeed, w thin the $m$ ean- eld version of the $M$ axw ellm odel the particles scatter random ly one w ith another irrespectively of their positions. This corresponds to random ly picking pairs of agents for interaction, w ith no care of the
(possibly com plex) structure of their relationships. In reality the econom ic activity goes along links in a com plex socialnetw ork [64, 65]. Indeed, recently there w ere investigations of the role of netw ork topology in wealth distribution [34, 66]. W e $m$ ay consider the present $m$ odel as an approxim ation of that netw ork by a com plete graph.
$T$ he $m$ ain di erence from the $m$ ean-eld $M$ axwell m odel is that the energy of the granular gas decreases by dissipation, while the average total wealth of the agents increases due to the econom ic activity. The sign of the non-conservation is therefore opposite in the two cases. $W$ hile the form of the equations $m$ ay rem ain the sam $e$, the solution cannot be directly continued from one dom ain to another. Therefore, while the case of dissipation is relatively well understood, new approaches are needed in the case of production. That is the aim of the present work.

## II. IN TERACTINGAGENTSASSCATTERING PARTICLES

## A. D escription of the process

Im agine a society of N agents, each of which possess certain $w$ ealth $v_{i}, i=1 ; 2 ;::: ; N$. T im e-to tim e the agents interact in essentially instantaneous \collision" events, when certain fraction of the wealth can be exchanged. M oreover, we suppose the system is open and the interaction can catalyze an increase of the total w ealth of the two interacting agents. Indeed, the source of the hum an w ealth lies beyond our society and the ultim ate cause is the energy poured to the Earth from the Sun. N onetheless, the extemalenergy is utilized only through a hum an activity and we sim plify the problem by assum ing that the net increase of w ealth happens at the very $m$ om ents of agents' interaction.

W e also assum e that only pairw ise interaction occurs. This m ay be a very crude assum ption, as conporate decisions a ect m any agents sim ultaneously. H ow ever, we expect the presence of $m$ ultilateral interactions does not a ect the essentialm echanism $s$ in work here.
$T$ he dynam ics of our $m$ odel is described as follow s. In each tim e step ta pair ofagents ( $i ; j$ ) is chosen random ly. They interact and exchange w ealth according to the sym m etric rule

$$
\begin{array}{lll}
v_{i}(t+1)  \tag{1}\\
v_{j}(t+1) & = & 1+ \\
& 1+ & v_{i}(t) \\
v_{j}(t)
\end{array}
$$

A 11 other agents leave their wealth unchanged, $\mathrm{V}_{\mathrm{k}}(t+$ 1) $=v_{k}(t)$ for $a l l k$ di erent from both $i$ and $j$. The param eter $2(0 ; 1)$ quanti es the wealth exchanged, while $>0 \mathrm{~m}$ easures the ow ofwealth from the outside. T he process is sketched schem atically in F ig. 1 .
$T$ his rule is sim ilar to those studied in $[43,53,56]$ and sim ulated num erically in $[29,31,44,47]$ but we consider it slightly $m$ ore realistic as it treats the agents in a priori sym $m$ etric $m$ anner. It also em braces various sources of

FIG. 1: Schem atic picture of the scattering process, where the wealth is exchanged and produced.
wealth non-conservation $w$ ith in a single e ective param eter. In fact, also the form ulation based on the sim ilarity w th the problem of directed polym ers [21, 22] can be reduced to a rule of the form sim ilar to (1). Therefore, we are studying a representative of a whole class of related m odels and we expect the analytical results we w ill present have rather broad relevance.

## B. $K$ inetic equation

The equation (1) describes a m atrix multip licative stoch astic process of vector variable $v(t)$ in discrete tim e $t$. P rocesses of this type are thoroughly studied e. g. in the context of granular gasses. Indeed, if the variables $v_{i}$ are interpreted as energies corresponding to i-th granular particle, we can $m$ ap the process to the $m$ ean- eld lim it of the $M$ axw ellm odel of inelastic particles. H ow ever, the energy dissipation conventionally quanti ed by the restitution coe cient im plies now the negative value $<0$, contrary to our assum ption $>0$. W e will see later that this apparently sm all variation $m$ akes big di erence in the analytical treatm ent of the process.

The full inform ation about the process in time $t$ is contained in the N -particle joint probability distribution $P_{N}\left(t ; v_{1} ; v_{2} ;:: ; \mathrm{v}_{\mathrm{N}}\right)$. H ow ever, we can write a kinetic equation involving only one- and two-particle distribution functions

$$
\begin{align*}
& P_{1}(t+1 ; v) \quad P_{1}(t ; v)=\frac{2}{N} \quad P_{1}(t ; v)+ \\
& \quad Z  \tag{2}\\
& +\quad P_{2}\left(t ; v_{i} ; v_{j}\right) \quad\left((1 \quad+) Y+\quad V_{j} \quad v\right) d v_{i} d v_{j}
\end{align*}
$$

which $m$ ay be continued to give eventually an in nite hierarchy of equations of BBGKY type. A s a standard approxim ation we use the factorization

$$
\begin{equation*}
P_{2}\left(t ; v_{i} ; v_{j}\right)=P_{1}\left(t_{;} v_{i}\right) P_{1}\left(t ; v_{j}\right) \tag{3}
\end{equation*}
$$

which breaks the hierarchy on the low est level, neglecting the correlations betw een the wealth of the agents,
induced by the scattering. In fact, this approxim ation becom es exact for N ! 1 . Therefore, in them odynam ic lim it the one-particle distribution function bears all inform ation.

Rescaling the tim e as $=2 \mathrm{t}=\mathrm{N}$ in the them odynam ic lim it N ! 1 , we obtain for the one-particle distribution function $\mathrm{P}(\mathrm{iv})=\mathrm{P}_{1}(\mathrm{t} ; \mathrm{v})$ a Boltzm ann-like kinetic equation

$$
\begin{align*}
& \frac{@ P(v)}{Z^{@}}+P(v)=  \tag{4}\\
& \quad P\left(v_{i}\right) P\left(v_{j}\right) \quad\left((1 \quad+) Y+\quad v_{j} \quad v\right) d v_{i} d v_{j}
\end{align*}
$$

which describes exactly the process (1) in the lim it $N$ ! 1 . This equation has the same form as the $m$ ean-eld version for the well-studied M axwell m odel of inelastically scattering particles [54, 56, 57]. The m ain di erence consists in the fact that here the w ealth increases, while in inelastic gas the energy decreases. This seem ingly little di erence has, how ever, deep consequences for the solution of Eq. (4) .
$N$ ote also that $w$ ithin the fram ew ork ofM axw ellm odel the distributions are expressed in term $s$ of velocities, while our dynam ical variables correspond rather to energies of the particles.
III. SOLUTION OFTHEKINETICEQUATION

> A. Self-sim ilar solutions

N ote rst that the average wealth $v={ }^{R} v P(v) d v$ in the process described by the kinetic equation (4) grow s exponentially

$$
\begin{equation*}
v(\quad)=v(0) e \tag{5}
\end{equation*}
$$

and therefore Eq. (4) has no stationary solution. H ow ever, we m ay look for a quasi-stationary self-sim ilar solution in the form 50, 54, 56, 57]

$$
\begin{equation*}
P(; v)=\frac{1}{v()}\left(\frac{v}{v(~)}\right): \tag{6}
\end{equation*}
$$

U sing the Laplace transform ${ }^{\wedge}(x)=\begin{array}{cl}R_{1} & (w) e^{x w} d w \\ 0\end{array}$ we can write a non-localdi erentialequation for the scaling function in the form

$$
\begin{equation*}
x^{\wedge}(x)+{ }^{\wedge}(x)={ }^{\wedge}((1+) x)^{\wedge}(x) \tag{7}
\end{equation*}
$$

A hint about possible solutions can be pbtained from a special exactly solvable case $=2^{2}+2$. It can be easily veri ed [54] that the function ${ }_{\mathrm{p}}^{1}(\mathrm{x})=$ $\left(1+{ }^{\mathrm{P}} \overline{2 \mathrm{x}}\right) \mathrm{e}^{\mathrm{P}} \overline{2 \mathrm{x}}$ is a solution of (7). Inverting the Laplace transform we obtain the corresponding wealth distribution $1(w)=\frac{1}{2} w^{5=2} \exp \left(\frac{1}{2 w}\right)$ which has sim ilar form as obtained in previous studies [13, 21, 22]. H ow ever, in this case the value of is negative, which contradicts our assum ption of wealth increase, while for $>0$
the above idea leading to the function ${ }^{{ }_{1}}(x)$ does not w ork. Therefore, we m ust look for altemative ways. T he leading idea ofour approach is that equation (7) is nearly local for sm all values of and. Therefore, we will expand the factors on the RHS of Eq. (7) in Taylor series in and and perform the lim it ; 0. As the param eters and quantify the am ount of w ealth increase and exchange in single trade event, we interpret the latter lim it as the lim it of continuous trading. In fact, such lim it should involve also a rescaling oftime , but because we are interested only in stationary regin e, the explicit tim e dependence does not enter our considerations.

It should be also stressed that an im portant feature can be inferred from the observation that the system behaves di erently for positive and negative. Indeed, it suggests a singularity at the point of precise conservation of wealth, $=0$.

FIG.2: Solution of the equation $f_{0}(;$; $(1+\quad) \quad+$
$1=0$ for $=0: 1$ and $=0: 0025$ (fill line) and $=0: 004$ (dashed line).
B. P ow er-law tails

Them ain concem in em pirical studies of w ealth distribution is about the shape of tails, which assum es powerlaw form. The behavior of the distribution (w) for w ! 1 can be deduced from the singularity of the Laplace transform ${ }^{\wedge}(\mathrm{x})$ at x ! 0 . Therefore, we assum e the follow ing behavior [54, 57]

$$
\begin{equation*}
\wedge(x)=1 \quad x+A \dot{x} j+::: \text { for } x!0 \tag{8}
\end{equation*}
$$

where $2(1 ; 2)$. Thistype ofsingularity results in the power-law tail as (w) w ${ }^{1}$ forw ! 1 . Insertion of (8) into (7) leads to a transcendentalequation for the exponent

$$
\begin{equation*}
(1+")+1 \quad "=0 \tag{9}
\end{equation*}
$$

the solution of which is illustrated in F ig. 2. O bviously, there is alw ays a trivial solution $=1$. The pow er-law tail is due to another, non-trivial solution, which falls into the desired interval $(1 ; 2)$ only for certain values of the param eters and . W e can see the allow ed region in F ig. 3; solution in the range $2(1 ; 2)$ exists $w$ ithin the shaded region. W e can also see that xed value of
de nes a line in the - plane. W e can approach the lim it ! 0 , ! 0 while keeping constant. This is to be interpreted as continuous trading, as the am ount of wealth exchange and increase in a single trading step is in nitesim ally sm all. M aking this, the non-localterm s in Eq. 7) becom e local and we can expect to obtain an ordinary di erentialequation, soluble by standard $m$ ethods.

FIG.3: Solution in the range $2(1 ; 2)$ exists $w$ ith in the shaded region. dashed line corresponds to $=2$, dash-dotted line corresponds to $=1$ and full line to the solution $=\frac{3}{2}$.
C. C ontinuous trading lim it

Indeed, expanding (9) we obtain the follow ing form ula relating and for xed in the lim it of continuous trading ! 0, ! 0 :

$$
\begin{equation*}
=\frac{1}{2}{ }^{2}+O\left({ }^{3}\right)+O\left({ }^{2}\right): \tag{10}
\end{equation*}
$$

T he leading correction term to (10) depends on the value of ; for $1 \ll 3=2$ it is of order $O$ ( ${ }^{2}$ ), for $3=2<$ $<2$ it is of order $O\left({ }^{3}\right)$, while in the special point
$=3=2$ we should include both correction term $s$, as they are of the sam e order $O\left({ }^{3}\right)$. System atic expansion in is developed in A ppendixA.

Taking the same lim it with xed in Eq. 7) we obtain, using (10), the follow ing equation

$$
\begin{equation*}
\frac{1}{2} x^{\wedge}{ }^{\infty}(x)+\frac{1}{2}{ }^{\wedge}(x)+{ }^{\wedge}(x)=0: \tag{11}
\end{equation*}
$$

Of the two independent solutions of (11) only one has correct asym ptotics ${ }^{\wedge}(\mathrm{x})$ ! 0 for $\mathrm{x}!+1$. It can be expressed using $m$ odi ed B essel function

$$
\begin{equation*}
\wedge^{\wedge}(x)=C^{0} x^{=2} K \quad\left(2^{p-1} 1^{p} \bar{x}\right) \tag{12}
\end{equation*}
$$

where the constant $C^{0}$ is xed by the nom alization ${ }^{\wedge}(0)=1$. Inverting the Laplace transform we nally obtain the wealth distribution

$$
\begin{equation*}
(w)=C w \quad{ }^{1} \exp \left(\frac{1}{w}\right) \tag{13}
\end{equation*}
$$

with $C=(1)=(1)$.
W e can see that the distribution obtained exhibits the desired power-law behavior for large wealth. M oreover, it has a maximum at a nite value of $w=W_{m a x}$ ( 1 ) $=(+1)$ and depression for low wealth values. The size of the depletion is determ ined by the exponential term in (13), i. e. by the sam e value of which determ ines the power in the power-law. T his corresponds to the idea presented e. g. in Ref. [11] stating that it is the value of the lower bound for the allowed wealth which determ ines the value of the exponent. H ere, how ever, this result com es purely form ally as a result of the analytic com putation. In our approach it is the interplay between wealth increase (param eter ) and wealth exchange (param eter ) that dictates the value of the exponent .

## D. C orrections for $n$ ite trading in one step

Expanding the equation (7) in powers of and it is possible to include system atic corrections to equation (11) and therefore corrections to wealth distribution (13) for nite am ount of wealth increase and exchange in single trading step. D etails of the calculations are given in A ppendix $A$; here we only sum $m$ arize the results.

The expansion (10) of the param eter in powers of can be continued as

$$
\begin{align*}
= & \frac{1}{2}{ }^{2}+ \\
& +\frac{1}{2} \quad{ }^{2} \quad \frac{(1)(2}{6}{ }^{3}+  \tag{14}\\
& +O\left({ }^{4}\right)+O\left(\begin{array}{ll}
{ }^{4} & 2
\end{array}\right):
\end{align*}
$$

C orrespondingly, the wealth distribution, expanded in powers of is

$$
\begin{align*}
(\mathrm{w})= & \frac{(1)}{(1)} \mathrm{w}^{1} \exp \frac{1}{\mathrm{w}} \\
& 1+\frac{1}{3} \\
& \frac{2}{\mathrm{w}} \frac{1}{\mathrm{w}^{2}} \\
& \frac{1}{2} \quad \ln w+\frac{1}{\mathrm{w}} \quad 01  \tag{15}\\
& 0\left({ }^{1}\right)+ \\
& O\left({ }^{4}\right)+O\left(\begin{array}{ll}
4 & 2
\end{array}\right)
\end{align*}
$$

where the constants 01 and 10 are given in A ppendix $\mathbb{A}$. W e show in Fig . 4 the wealth distribution according to (15) for $=1: 7$ and several positive values of , nam ely for $=0: 03,0: 1$, and $0: 3 . \mathrm{W}$ e can see that the distribution is a ected $m$ ainly at sm all values of wealth, shifting the m axim um tow ard sm allerw when increases. On the contrary, the tail of the distribution is nearly una ected, show ing universal and robust pow er-law behavior.

FIG. 4: W ealth distribution according to Eq. 15 for ! 0 (fiull line), $=0: 03$ (dashed line), $=0: 1$ (dash-dotted line), and $=0: 3$ (dotted line).

Let us stress again that the solution known for $<0$ cannot be properly continued to the region of $>0$, due to the presence of singularity at $=0$. The singularity can be seeen e. g. in the behavior of the solution of Eq. 91, as show $n$ in Fig. 5. H ow ever, for $=3=2$ the form ula (13) describes the solution of (7) on both lim its
! $0^{+}$and ! 0 . This implies that the singularity is rather weak, because the solution of Eq . (7) is continuous in , and only the derivative w ith respect of has a jump at $=0$. O ne $m$ ay speculate about the fate of the singularity if we allowed and not xed parameters but random processes them selves. M ost probably the singularity would vanish but nal answer is left for future work.

## IV . CONCLUSIONS

W e form ulated a m odel of wealth production and exchange, where agents random ly interact pairw ise. U sing the analogy $w$ ith the $m$ ean-eld version of the $M$ axw ell m odel for inelastic scattering of granular particles we obtain analytical results for the wealth distribution.
$T$ he dynam ics of the m odel is govemed by a kinetic equation for one-particle distribution function. W e look for self-sim ilar scaling solutions, corresponding to rede n ing the unit of wealth after each w ealth increase. The form of these solutions is given by a non-localdi erential

FIG.5: Solution of equation (9) for $=3=2$ in the ranges $>0$ (fiull line) and $<0$ (dashed line). $N$ ote the singularity at $=0 \mathrm{which} m$ eans that wem ust skip from one of the three solutions of (9) to another one.
equation, exactly soluble only in the practically irrelevant case of net w ealth decrease. T herefore we tumed to approxim ation schem es.

F irst, we looked at the behavior for large w ealth. T he tail of the wealth distribution has a power-law form, and its exponent is determ ined by the interplay betw een the intensity of the wealth exchange and the am ount of wealth produced. The form line in the - plane with xed is found, depending quadratically on for ! 0 . The physically allowed values $2(1 ; 2)$ determ ine a hom-shaped region in the - plane.
$T$ he second approxim ation consisted in taking the lim it of continuous trading, $m$ eaning sm all wealth production and sm all exchange $w$ ithin a single trading operation, while keeping the exponent constant. Here we obtained closed form ula for the entire wealth distribution, which has power-law tail as expected and a maxim um at certain (low) wealth value. The form of the wealth distribution corresponds to those found in previous studies [13, 21, 22]. It is interesting to note that this general form has one-to-one correspondencebetw een the position $\mathrm{w}_{\mathrm{m}}$ ax of them axim um of the distribution and the value of the exponent. T here are few agents having wealth below $\mathrm{w}_{\mathrm{m}}$ ax.$T$ his suggests that the intuition form alized e. g . in [11, 13], that the exponent is \tuned" by the low wealth behavior of the distribution, $m$ ay be in work quite generally. H ere, the free param eters are apparently the w ealth production and exchange, but in reality these param eters $m$ ay be them selves tuned by a $m$ echanism which xes the position of the $m$ axim um of the wealth distribution, i. e. the low est w ealth com patible w ith survival.

H ow ever, there is still open question of the speci c values of the exponent, which are quite robust in di erent societies. It seem s, also on the basis of our results, that it cannot be explained by the bare $m$ echanism of eco-
nom ic exchange and som e other ingredient, possibly of sociological origin, is required.

A gency of the C zech Republic.

Let us start $w$ th the special value $=3=2$. H ere, the equation (9) has an explicit solution in the form

APPENDIXA: SYSTEMATIC EXPANSION FOR SMALL AND.

I w ish to thank P aul K rapivsky and E li $\mathrm{Ben}-\mathrm{N}$ aim for stim ulating com $m$ ents and discussions. This work was supported by the pro ject No. 202/01/1091 of the G rant

H ow ever, the non-localdi erentialequation (7) stilldoes not yield explicit solution. Inverting the expression A A we get the follow ing series expansion

$$
=\frac{1}{4}^{2} \frac{1}{12}^{3}+\frac{1}{16}^{4} \frac{7}{144}^{5}+\frac{113}{2592}^{6}+0 \quad{ }^{7}:(\text { A } 2)
$$

For general value of the variable is expressed as a series in two sm all param eters and $=2\left({ }^{1)}\right.$, which coincide only if $=3=2$. Therefore, we can w rite

$$
\begin{equation*}
=2_{m ; n=0}^{\mathrm{X}^{\mathrm{B}}} \mathrm{mn}^{\mathrm{m}+2(1) \mathrm{n}} \tag{A3}
\end{equation*}
$$

and the various term s take variable precedence in the order of sm allness when ! 0 , depending on the value of . For the rst severalcoe cients we have

$$
\begin{align*}
& 00=\frac{1}{2}  \tag{A4}\\
& \left.10=\frac{(1)(2}{}=1\right)  \tag{A5}\\
& 01=\frac{1}{6}: \tag{A6}
\end{align*}
$$

Starting from the expansion A 3) we can convert the rst order non-local di erential equation (7) for ${ }^{\wedge}(x)$ into in nite-order local di erential equation for (w). The price to pay for it is that the coe gients in the latter equation contain the $m$ om ents $k=(w) w^{k} d w$ of the solution itself. Indeed, we can w rite

$$
\begin{array}{r}
\wedge((1 \quad+) x)=\lim _{y!x} \exp \quad(\quad) x \frac{d}{d y} \quad{ }^{\wedge}(y) \\
{ }^{\wedge}(x)=\lim _{y!0} \exp \quad x \frac{d}{d y} \quad{ }^{\wedge}(y): \tag{A8}
\end{array}
$$

T herefore, we obtain a linear com bination of term s of the follow ing form

$$
\begin{equation*}
x^{m+n} \frac{d^{m} \wedge(x)}{d x^{m}} \frac{d^{n} \wedge(0)}{d x^{n}} \tag{A9}
\end{equation*}
$$

which, after inverse Laplace transform, give rise to term $s$

$$
\begin{equation*}
(1)^{m+n} \quad \frac{d^{m+n}}{d w^{m+n}}\left[w^{m} \quad(w)\right]: \tag{A10}
\end{equation*}
$$

H ow ever, the rst twom om ents are xed by de nition. Indeed, the nom alization of the probability distribution xes the zeroth $m$ om ent and the xed average wealth, im posed by the scaling condition (6) xes the rst $m$ o$m$ ent, so that $0=1=1$. This consideration leads to the equations for low est correction to the solution (13), which are free of unknow $n$ higher $m$ om ents.

G enerally, the solution can be then expressed in the form of the series in powers of and $2(1)$

$$
\begin{equation*}
(w)=0(w)_{m ; n=0}^{X_{m}^{A}} \underset{m}{ }(w)^{m+2(1) n}: \tag{A11}
\end{equation*}
$$

W e assume $00(\mathrm{w})=1$. The norm alization $m$ ust be independent of , which can be w ritten as

$$
\mathrm{Z}_{1} \quad 0(\mathrm{w}) \mathrm{mn}(\mathrm{w}) \mathrm{dw}=\mathrm{m} 0 \mathrm{no}:
$$

T herefore, the low est term obeys the equation

$$
\begin{equation*}
\frac{w^{2}}{2} 0_{0}^{0}(w)+\frac{+1}{2} w \quad \frac{1}{2} \quad 0(w)=0 \tag{A13}
\end{equation*}
$$

which has the follow ing solution satisfying the nom alization A 12

$$
\begin{equation*}
o(w)=\frac{(1)}{()} w^{1} \quad \exp \frac{1}{w}: \tag{A14}
\end{equation*}
$$

Indeed, it coincides $w$ ith the result of (13).
$T$ he next tw o term s satisfy the follow ing equations

$$
\begin{array}{llll}
\frac{w^{2}}{2} & 0 \\
10 & (w)=\frac{1}{3} & & \frac{1}{w}  \tag{A16}\\
\frac{w^{2}}{2} & 0 \\
01 & (w)= & \frac{1}{2} \quad \frac{1}{2} & (w \quad 1)
\end{array}
$$

which can be easily solved.W e obtain

$$
\begin{align*}
& 10(w)=\frac{1}{3} \frac{2}{w} \frac{1}{w^{2}}  \tag{A17}\\
& 01(w)=\frac{2}{2} \frac{1}{2} \quad \ln w+\frac{1}{w} \tag{A18}
\end{align*}
$$

and the constants 01 ; 10 are xed by the norm alization condition A 12). We nd explicitly

$$
\begin{align*}
10 & =  \tag{A19}\\
01 & =\ln (1) \quad(1)+\frac{1}{1}
\end{align*}
$$

where $(x)={ }^{0}(x)=(x)$ is the logarithm ic derivative of the gam $m$ a function.
