#### Abstract

W e present a theoreticalanalysis of the appearance ofentanglem ent in non-interacting m esoscopic structures. O ur setup involves tw o oppositely polarized sources in jecting electrons of opposite spin into the two incom ing leads. The $m$ ixing of these polarized stream $s$ in an ideal four-channelbeam splitter produces tw o outgoing stream $s$ w ith particular tunable correlations. A B ell inequality test involving cross-correlated spin-currents in opposite leads signals the presence of spin-entanglem ent between particles propagating in di erent leads. W e identify the role of ferm ionic statistics and projective $m$ easurem ent in the generation of these spin-entangled electrons.

Quantum entangled charged quasi-particles are perœived as a valuable resource for a future solid state based quantum inform ation technology. R ecently, speci c designs form esoscop ic structures have been proposed which generate spatially separated stream s of entangled parti-
 $m$ ents have been conceived which test for the presence
 U sually, entangled electron-pairs are generated through speci c interactions (e.g., through the attractive interaction in a superconductor or the repulsive interaction in a quantum dot) and particular $m$ easures are taken to separate the constituents in space (e.g., involving beam splitters and appropriate lters). H ow ever, recently it has been predicted that non-local entanglem ent as signalled through a violation of $B$ ell inequality tests can be
 The im portant task then is to identify the origin of the entanglem ent; candidates are the ferm ionic statistics, the beam splitter, or the pro jection in the B ellm easurem ent

H ere, we report on our study ofentanglem ent in a noninteracting system, where we m ake sure, that the particles encounter the Bell setup in a non-entangled state. Nevertheless, we nd the Bell-inequality to be violated and conclude that the concom ittant entanglem ent is produced in a w ave function projection during the B ellm easurem ent. W e note that wave function projection as a resource of non-local entanglem ent is known for singleparticle sources (Fock states) [idi], a schem e working for both bosons and ferm ions. W hat is di erent in Refs.事, $m$ any-particle states in local therm al equilibrium. It is then essential that one dealsw ith ferm ions; w ave function projection cannot create entanglem ent out of a them al source ofbosons.

The generic setup for the production of spatially separated entangled degrees of freedom usually involves a source in jecting the particles carrying the intemal degree

FIG.1: M esoscopic nom alm etalstructure w ith a beam splitter generating tw o stream $s$ of electrons $w$ ith tunable correlations in the two outgoing $\mathrm{arm} \mathrm{s} \mathrm{u}^{\prime}$ and $\mathrm{d}^{\prime}$. T he source (left) in jects polarized (along the z-axis) electrons into the source leads $s^{\prime}$ and $s^{\prime}$. The beam splitter $m$ ixes the tw $o$ incom ing stream s w ith a m ixing angle \#. The scattered (or outgoing) beam $s$ are analyzed in a Bell type coincidence $m$ easurem ent involving spin-currents projected onto the directions a (in the $\mathrm{u}^{\prime}$ lead) and b (in the $\mathrm{d}^{\prime}$ lead). The in jection reservoins are voltage ( $V$ ) biased against the outgoing reservoirs. The Bell inequality test signals the presence of entanglem ent within the interval $\ddagger$ \# $45 \mathrm{j}<12: 235$. W e relate this entanglem ent to the presence of spin-triplet correlations in the projected part of the scattered w avefunction describing electronpairs distributed betw een the arm $s$.
particles in space, see Fig. '111. In addition, ' lters' $m$ ay be used to inhibit the propagation of unw anted com ponents
 forcing a pure ow ofentangled particles in the outgoing leads. T he successfiul generation of entanglem ent then is m easured in a Bell inequality type setup [ $\mathrm{I}_{1}^{\prime} \underline{1}_{1}^{1}$. A surprising new feature has been recently predicted with a Bell inequality test exhibiting violation in a non-interacting
 duces the entanglem ent $m$ anifested in the Bell inequality violation and it is this question which we w ish to address in the present work. In order to do so, we describe theoretically an experim ent where we make sure, that the particles are not entangled up to the point where the correlations are $m$ easured in the Bell inequality setup; nevertheless, we nd them violated. W e trace this vi-
olation back to an entanglem ent which has its origin in the con uence of various elem ents: i) the Ferm istatistics provides a noiseless stream of incom ing electrons, ii) the beam splitterm ixes the indistinguishable particles at one point in space rem oving the inform ation about their ori$g i n, i i i)$ the splitter directs the $m$ ixed product state into the two leads thus organizing their spatial separation, iv) a coincidence $m$ easurem ent pro jects the $m$ ixed product state onto its (spin-)entangled com ponent describing the electron pair split betw een the two leads, v) m easuring the spin-entangled state in a Bell inequality test exhibits violation (the steps iv) and v) are united in our setup). N ote, that the sim ple ferm ionic reservoir de ning the source in Ref. ${ }_{10}$ il, in jects spin-entangled pairs from the beginning; hence an analysis of this system cannot provide a de nitive answer on the $m$ inim al setup providing spatially separated entangled pairs since both the source and/or the pro jective B ellm easurem ent could be responsible for the violation.
Below, we pursue the follow ing strategy: W e rst dene a particle source and investigate its characteristic via an analysis of the associated tw o-particle density m atrix. W e then de ne the corresponding pair wave function (thus reducing the $m$ any body problem to a twoparticle problem ) and determ ine its concurrence follow ing the de nition of Schliem ann et al. 11 guishable particles ( $m$ ore generally, one could calculate the S later rank of the w ave function, cf. Ref. $]_{1}^{1} \overline{1}_{1}^{1}$ here, we deal w ith a four-dim ensional one-particle $H$ ilbert space where the concurrence provides a sim ple and quantitative $m$ easure for the degree of entanglem ent). For our specially designed source we nd a zero concurrence and hence our incom ing beam is not entangled. W e then go over to the scattering state behind the (tunable) beam splitter and reanalyze the state $w$ ith the help of the tw oparticle density matrix. W e determ ine the associated two-particle wave function and nd its concurrence; com paring the results for the incom ing and scattered wave function, we will see that the concurrence is unchanged, a simple consequence of the unitary action of the beam splitter. H ow ever, the $m$ ixer rem oves the inform ation on the origin of the particles, thus preparing an entangled wave function com ponent in the output channel. Third, we analyze the com ponent of the wave function to which the Bell setup is sensitive and determ ine its degree of entanglem ent; depending on the $m$ ixing angle of the beam splitter, we nd concurrencies betw een 0 (no entanglem ent) and unity ( m axim al entanglem ent). $F$ inally, we determ ine the violation of the Bell inequality asm easured through tim e-resolved spin-current crosscorrelators and nd agreem ent betw een the degree of violation and the degree of entanglem ent of the pro jected state as expressed through the concurrence.

Our source draws particles from two spin-polarized reservoirs $w$ th opposite polarization directed along the z -axis. The polarized electrons are in jected into source
leads $s^{\prime}$ and $s^{\prime}$ and are subsequently mixed in a tunable four-channelbeam splitter, see F ig. ${ }^{\prime} 1 \mathbf{1}$.'. The outgoing channels are denoted by ' $\mathrm{u}^{\prime}$ (for the upper lead) and $\mathrm{d}^{\prime}$ (the dow $n^{\prime}$ lead). The spin-correlations in the scattering channels $\mathrm{u}^{\prime}$ and $\mathrm{d}^{\prime}$ are then analyzed in a Bell inequality test. T he polarized reservoirs are voltage biased w th $\mathrm{eV}={ }_{\mathrm{B}} \mathrm{H}=2$ equal to the m agnetic energy in the polarizing eld H; the incom ing electron stream s then are fully polarized (the $m$ agnetic eld is con ned to the reservoirs).

The spin-correlationsbetw een electrons in leads $X^{\prime}$ and $y^{\prime}$ are conveniently analyzed $w$ th the help of the twoparticle density $m$ atrix (or pair correlation function)
w ith trace over states of the Ferm i sea. Here, ${ }^{\wedge} x$ are eld operators describing electrons with spin in lead $\mathrm{x}^{\prime}$ and ${ }^{\wedge}$ is the density operator. The pair correlation function ( $1_{1}^{1}$ ) is conveniently expressed through the oneparticle correlators $G^{x y}(x ; y) \quad h_{x}^{\wedge}(x){ }_{y}(y) i$,

The one-particle correlators can be written in term $s$ of a product of orbital and spin parts, $G^{x y}(x ; y)=$ $G^{x y}(x ; y)^{x y}(;)$, and split into equilibrium and excess term S ,

$$
\begin{equation*}
G^{x y}(x ; y)=G_{e q}(x ; y) \underset{e q}{x y}(;)+G_{e x}(x ; y) \underset{e x}{x y}(;) ; \tag{3}
\end{equation*}
$$

$w$ ith $G_{\text {ex }}(x ; y)$ vanishing at zero voltage $V$ and zero polarization eld H.

In order to nd the two-particle density $m$ atrix in the source leads $s^{\prime}$, $s^{\prime}$ we $m$ ake use of the scattering states

$$
\begin{aligned}
& \hat{s}_{s}=e^{X} e^{i k x} \hat{a}_{k}+e^{i k x}\left(\cos \# e^{i^{\prime}} \hat{\theta}_{k}+\sin \# e^{i} \hat{d_{k}}\right) ; \\
& \hat{s}_{s}={ }^{X} e^{k} e^{i k x} \hat{\mathrm{O}}_{k}+e^{i k x}\left(\cos \# e^{i^{\prime}} \hat{d_{k}} \quad \sin \# e^{i} \hat{\theta}_{k}\right) ;
\end{aligned}
$$

where $\hat{a}_{k}, \hat{b}_{k}$ denote the anninilation operators for electrons in the source reservoirs $s$ and $s w$ ith $m$ om entum $k$ and spin 2 "; \# polarized along the $z$-ax is and tim e evolution / $\exp \left(i_{k} t=h\right), k=h^{2} k^{2}=2 m$; the operators $\theta_{k}$ and $\hat{d_{k}}$ annihilate electrons in the reservoirs attached to the outgoing leads ' u ' and $\mathrm{d}^{\prime}$ ', respectively. A lso, we $m$ ake use here of the standard param etrization of a reectionless four-beam splitter,
with the angles \# $2(0 ;=2), ' ; 2(0 ; 2)$; without loss of generality we will assum $e^{\prime}=\quad=0$ in what follows. The orbital part of the one-particle correlator
$G^{x y}\left(\begin{array}{lll}x & y\end{array}\right) \quad G\left(\begin{array}{ll}x & y\end{array}\right)$ takes the form

$$
\begin{align*}
& G_{\text {eq }}(x)=\frac{\sin k_{F}}{x} ;  \tag{5}\\
& G_{\text {ex }}(x)=e^{i\left(k_{F}+k_{V}\right) x} \frac{\sin k_{V} x}{x} ; \tag{6}
\end{align*}
$$

w ith $\mathrm{k}_{\mathrm{V}}=\mathrm{k}_{\mathrm{F}}\left(\mathrm{eV}=_{\mathrm{F}}\right)$ and $\mathrm{F}_{\mathrm{F}}\left(\mathrm{k}_{\mathrm{F}}\right)$ the Ferm ienergy (wave vector) in the unbiased system. The spin factors for the equilibrium and excess parts read,

$$
\begin{align*}
& { }_{e q}^{x x}(;)=h \quad j i ;  \tag{7}\\
& \underset{\text { ex }}{\text { ss }}(;)=h \text { j"ih" } j i ; \quad \underset{e x}{s s}(;)=h \quad j \# i h \# j i ;
\end{align*}
$$

the latter describing the in jection of polarized electrons into the leads $s^{\prime}$ and $s^{\prime}$. Finally, the cross correlation function betw een the source leads vanishes, $G{ }^{\text {ss }}\left(\begin{array}{ll}x & y\end{array}\right)=$ 0 , and the nal result for the excess part of the pair correlation function betw een source leads reads

This result then describes the injection of two uncorrelated stream s of polarized electrons into the leads $s^{\prime}$ and $s^{\prime}$. Furthem ore, statistical analysis [12] tells that the Ferm i statistics enforoes in jection into each lead of a regular stream of particles separated by the singleparticle correlation time $v=h=e V$. The full $m$ any body description then is conveniently reduced to a twoparticle problem where the two reservoirs in ject a sequence of electron pairs pesiding in the wave function
 particle wave functions associated w ith electrons in the upper (low er) source lead. T his w ave function is a sim ple Slater determ inant and hence non-entangled according to [11] 1 .

Next, we extend the above analysis to the outgoing leads ' l ' and $\mathrm{d}^{\prime}$. T he scattering states in the outgoing leads take the form

$$
\begin{gathered}
\hat{u}_{u}=e^{i k x} \hat{A}_{k}+e^{i k x}\left(\cos \# \hat{a}_{k} \quad \sin \# \hat{b}_{k}\right) ; \\
\hat{d}_{d}=e^{X} e^{i k x} \hat{d}_{k}+e^{i k x}\left(\cos \# \hat{b}_{k}+\sin \# \hat{a}_{k}\right):
\end{gathered}
$$

The excess particles in jected by the source leads now are m ixed in the beam-splitter and thus non-vanishing cross correlations are expected to show up in the leads $\mathrm{u}^{\prime}$ and $d^{\prime}$. The one-particle correlation function assum es the
 correlators

$$
\begin{aligned}
& { }_{e q}^{x x}(;)=h \text { ji; } \quad x 2 u^{\prime} ; d^{\prime} ; \\
& \operatorname{unu}_{\text {ex }}(;)=\cos ^{2} \# h \text { j"ih" } j i+\sin ^{2} \# h \text { j\#ih\# } j \text { i; }
\end{aligned}
$$

$$
\begin{aligned}
& \operatorname{ud}_{\mathrm{ex}}(;)=\operatorname{dux}_{\mathrm{ex}}(;) \\
& =\cos \# \sin \# h \text { j"ih" } j \text { i } h \text { j\#ih\# } j i:
\end{aligned}
$$

Evaluating the excess part of the two-particle crosscorrelations between the leads ' l ' and $\mathrm{d}^{\prime}$ at the sym $m$ etric position $x=y$ we nd

$$
\begin{align*}
& g_{\sim}^{u d}(x ; x) \text { ex }=j_{\text {ex }}(0) J \tag{10}
\end{align*}
$$

$$
\begin{aligned}
& +\cos ^{2} \# \sin ^{2} \# h_{1} \text { j\#in\# } j_{3} \text { ih } 2 \text { j"ih" } \mathrm{j}_{4} \mathrm{i} \text { : }
\end{aligned}
$$

Hence, a sym metric splitter (\# = =4) produces the spin correlations of a triplet state $\left[j \mathrm{ud} \mathrm{u}=j\right.$ " $\mathrm{i}_{\mathrm{u}} j \# \mathrm{i}_{\mathrm{d}}+$ $j \# i_{u} j " i_{d}=\overline{2}$ involving tw o electrons separated in di erent leads ' l ' and d ' but at equivalent locations $\mathrm{x}=\mathrm{y}$. T he generalcase with arbitrary $m$ ixing angle \# results in a density $m$ atrix describing a pure state involving the superposition $j \underset{t r}{u d} i+\cos 2 \# j \underset{s g}{u d} i$ of the above triplet state and the singlet state $\left[j \underset{\mathrm{sg}}{\mathrm{ud}} \mathrm{i}=j " i_{u} j \# i_{d} \quad j \# i_{u} j " i_{d}\right]={ }^{\mathrm{p}} \overline{2}$. $T$ he analoguous calculation for the two-particle density $m$ atrix describing electrons in the sam e outgoing lead $x^{\prime}$ equal ' $u$ ' or 'd' points to the presence of singlet correlations,

$$
\begin{align*}
& g_{\sim}^{x x}(x ; y){ }_{\text {ex }}=\xi_{\text {ex }}(0) \mathcal{J}^{2} h_{1 j} j_{4} \text { ih }_{2} j_{3 i} \tag{11}
\end{align*}
$$

A gain, the above results can be used to reduce the problem from itsm any-body form to a two-particle problem. Given the incom ing Slater determ inant ${ }_{\text {in }}^{12}$ we obtain the scattered state ${ }^{12}$ out through the transformation s" ! cos\# u" + sin \# d" describing scattered spin-" electrons originating from the source lead $s^{\prime}$ and s\# ! $\sin \#$ u\# + cos\# d\# for excess spin-\# electrons from $S^{\prime}$ (the wave functions $x=x$ describe electronsw ith orbital (spin) wave function x ( ) propagating in lead $x^{\prime}$ ). The resulting scattering $w$ ave function has the form

$$
\begin{array}{rl}
\begin{array}{lllllll}
12 \\
\text { out } & = & \sin \# \cos \# & 1 & 2 & 12 & 1 \\
\text { u } & \text { u } & \text { sg } & \text { d } & \text { d } & 12 \\
\text { sg } \\
& + & 12 & 12 \\
& \text { ud tr }
\end{array}+\cos 2 \# & 12 \\
& 12  \tag{12}\\
\text { ud } & \text { sg }
\end{array}
$$

where the rst two term $s$ describe the propagation of a spin-singlet pair w ith the wave function $\frac{12}{12}=\left(\begin{array}{cc}1 & 2 \\ \# & \#\end{array}\right.$ $\left.\begin{array}{l}1 \\ \# \\ n\end{array}{ }_{n}^{2}\right)={ }^{\mathrm{P}} \overline{2}$ in the upper and lower lead. The last two term s describe the com ponent where the electron pair is split between the ' u ' and $\mathrm{d}^{\prime}$ leads; it is a superposition of singlet-and triplet states $\left(\begin{array}{lll}12 \\ \operatorname{tr}\end{array}=\left(\begin{array}{lll}1 & 2 \\ 11 & \#\end{array}+\begin{array}{ll}1 & 2 \\ \# & { }_{n}\end{array}\right)=\overline{2}\right)$ $w$ ith corresponding sym $m$ etrized and anti-sym $m$ etrized orbitalw ave functions ${ }_{\mathrm{ud}}^{12}=\left(\begin{array}{llll}1 & 2 \\ \mathrm{u} & \mathrm{d}\end{array}+\begin{array}{c}1 \\ d\end{array}\right)=2$ and ${ }_{\mathrm{u}}^{12}=$ $\left(\begin{array}{llll}1 & 2 & 1 & 2 \\ u & d & d & d\end{array}\right)=2$. The entanglem ent present in these w ave functions is easily determ ined using the form alism developed by Schliem ann et al. [1] 1]: The wave function associated w ith a pair of electrons can he w ritten in term s of a single-electron basis f ig, ${ }^{12}=$ ij ${ }_{i}^{1} W_{i j}{ }_{j}^{2}$
where the anti-symmetric $m$ atrix $\mathrm{w}_{\mathrm{ij}}=\mathrm{w}_{\mathrm{ji}}$ guarantees for the proper sym $m$ etrization. The analysis sim pli es drastically for the case where the one-particle H ilbert space is four-dim ensional; then the concurrence $C()=8$ detw ( ) gives a quantitative $m$ easure for the entanglem ent present in the wave function,$C()=0$ for a non-entangled state and C() = 1 for a fully entangled w ave function. For our setup the one-particle basis is de ned asf u"; u\#; d"; d\#gand the matrix w ( out) describing the scattered state (12) assum es the form

$$
w_{i j}^{\text {out }}=p^{1}=\begin{array}{ccccc}
2 & 0 & \sin 2 \#=2 & 0 & \cos ^{2} \# 3 \\
2 & 0 & \sin 2 \#=2 & 0 & \sin ^{2} \# \\
0 & \sin ^{2} \# & 0 & 0 & 7 \\
& \cos ^{2} \# & 0 & \sin 2 \#=25
\end{array}:
$$

The concurrence of the scattering state (12 $\overline{2}_{1}$ ) vanishes, hence out is non-entangled and takes the form of an elem entary Slater determ inant. N ext, let us analyze the concurrence of that part of the scattering wave function to which our coincidence $m$ easurem ent in leads ' $u$ ' and ' $d^{\prime}$ is sensitive. T he com ponent describing the two particles split between the leads reads $\begin{aligned} & 12 \\ & \text { ud }\end{aligned}=\begin{array}{cc}12 \\ \text { ud } & 12 \\ \text { tr }\end{array}+$ cos2\# ${ }_{\text {ud }}^{12} \frac{12}{12}$, cf. (12는). This pro jected state is described by the $m$ atrix

$$
\mathrm{w}_{\mathrm{ij}}^{\mathrm{ud}}=\begin{array}{ccccc}
2 & 1 \\
P^{2} & 0 & 0 & 0 & \cos ^{2} \# \\
4 & 0 & 0 & \sin ^{2} \# & 0 \\
4 & 0 & \sin ^{2} \# & 0 & 0 \\
5
\end{array} ;
$$

from which one easily derives the concurrence $C\binom{12}{u d}=$ $\sin ^{2} 2 \#$; we conclude that the com ponent ${ }_{u d}^{12}$ detected in a coincidence $m$ easurem ent is entangled. Furtherm ore, the concurrence is equal to unity for the sym $m$ etric splitter $==4$ where we deal w ith a m axim ally entangled triplet state (note the loss of inform ation about which electron (from $s^{\prime}$ or $s^{\prime}$ ) enters the lead ' $u$ ' or $d^{\prime}$ ). W e conclude that a Bell inequality test sensitive to the split part of the wave function will exhibit violation. We attribute this violation to the combined action of i) the splitter where the inform ation on the identity of the particles is destroyed and the entangled com ponent ${ }_{\text {ud }}^{12}$ is prepared' and ii) the wave function projection inherent in the coincidence $m$ easurem ent and realizing' the entanglem ent.
 relations in the spin-entangled scattered wave function ${ }_{\text {out }}^{12}$. It involves the nite-tim e current cross-correlators $C_{a ; b}(x ; y ;) \quad h \hat{f_{a}}(x ;) \hat{I}_{b}(y ; 0)$ ii betw een the spincurrents $\hat{I}_{a}(x ;$ ) projected onto directions a (in lead $\mathrm{u}^{\prime}$ ) and partners $\hat{\mathrm{I}}_{\mathrm{b}}\left(\mathrm{y} ; 0\right.$ ) (in lead $\mathrm{d}^{\prime}$ ) pro jected onto b . $T$ hese correlators enter the Bell inequality ( $a$ and $b$ denote a second set of directions)

$$
\begin{equation*}
E(a ; b) \quad E(a ; b)+E(a ; b)+E(a ; b) j 2 \tag{13}
\end{equation*}
$$

via the current di erence correlators

$$
\begin{equation*}
E(a ; b)=\frac{\left.h\left[\hat{I}_{a}() \quad \hat{I}_{a}()\right] \hat{\mathbb{H}}_{b}(0) \quad \hat{I}_{b}(0)\right] i}{\left.h\left[\hat{I}_{a}()+\hat{I}_{a}()\right] \hat{\mathbb{H}}_{b}(0)+\hat{I}_{b}(0)\right] i}: \tag{14}
\end{equation*}
$$

The crossm easurem ent in di erent leads im plies that the setup is sensitive only to the spin-entangled splitpair part ${ }_{u d}^{12}$ of the scattering wave function and hence the Bell inequality can be violated. M aking use of the eld operators ${ }^{\wedge}{ }_{u}$ and ${ }^{\wedge}{ }_{d}$ describing the scattering states in the outgoing leads, we determ ine the irreducible current cross correlator and factorize into onbital and spin parts, $C_{a ; b}(x ; y ;)=C_{x ; y}() F_{a ; b}, w$ th $F_{a ; b}$ accounting for the spin projections. U sing standard scattering theory of noise [131], one obtains the orbital cross-correlator (only the excess part gives a nite contribution)

$$
\begin{equation*}
C_{x ; y}()=\frac{e^{2} \sin ^{2} 2 \#}{h^{2}} \sin ^{2} \frac{\mathrm{eV}( }{\mathrm{h}} \quad(\quad ;) ; \tag{15}
\end{equation*}
$$

w ith $(;)=2^{2}=\sinh ^{2}[\quad=\mathrm{h}], \quad=\left(\begin{array}{ll}\mathrm{x} & \mathrm{y}\end{array}\right)=\mathrm{V}_{\mathrm{F}}$,
the tem perature of the electronic reservoirs, and $V_{F}$ the Ferm i velocity. In order to arrive at the result (1515) we have dropped term $s \mathrm{sm}$ all in the param eter $j^{0-} \dot{F}_{\mathrm{F}}$ [13ㄴㄱㄱㄱ․ The spin pro jection $F_{a ; b}$ assum es the form

$$
\begin{aligned}
& \mathrm{F}_{\mathrm{a} ; \mathrm{b}}=\text { haj"ih" } \mathrm{b} \text { ihb j"ih" jai+ haj\#ih\# to ihb j\#ih\# jai }
\end{aligned}
$$

W e express this result in term sof the angles a and ' a describing the direction ofm agnetization in the $u^{\prime}$ lead lters and $\mathrm{b},{ }^{\prime}{ }_{\mathrm{b}}$ referring to the lters in the $\mathrm{d}^{\prime}$ lead and nd that $F_{a ; b}=F_{a ; b}=F_{a ; b}^{+}, F_{a ; b}=F_{a ; b}=F_{a ; b}$ and

$$
F_{a ; b}=\left(\begin{array}{ll}
1 & \cos \\
a & \cos \\
b & \cos ^{\prime}{ }_{a b} \sin a \sin b
\end{array}\right)=2 ;
$$

w ith ${ }^{\prime} \mathrm{ab}^{\prime}=$ ' $\mathrm{a}_{\mathrm{a}} \mathrm{I}_{\mathrm{b}}$. The correlator $\mathrm{E}(\mathrm{a} ; \mathrm{b})$ takes the form

$$
E(a ; b)=\frac{2 C_{x ; y}() F_{a ; b}^{+} F_{a ; b}+}{2 C_{x ; y}() F_{a ; b}^{+}+F_{a ; b}++} ;
$$

 ing the projected current averages one obtains $=$ $\mathrm{e}^{2}(2 \mathrm{eV}=\mathrm{h})^{2} \cos \mathrm{a} \cos \mathrm{b} \cos ^{2} 2 \#$ and $+=\mathrm{e}^{2}(2 \mathrm{eV}=\mathrm{h})^{2}$. $T$ he triplet state is rotationally invariant $w$ th in the plane
$\mathrm{a}=\mathrm{b}==2$ and choosing lters w ithin this equatorial plane the B ell inequality takes the form

$$
\frac{\mathrm{C}_{\mathrm{xiy}}\left(\mathrm { f } \left[\mathrm{cos}^{\prime}{ }_{\mathrm{ab}} \mathrm{cos}^{\prime}{ }_{\mathrm{ab}}+\cos ^{\prime}{ }_{\mathrm{ab}}+\cos ^{\prime}{ }_{\mathrm{ab}}\right.\right.}{2 \mathrm{C}_{\mathrm{xiy}}()++} 1:
$$

Its $m$ axim um violation is obtained for the set of angles $'_{a}=0, r_{b}=4,^{\prime}{ }_{a}=2,^{\prime}{ }_{b}=3=4$,

$$
\begin{equation*}
\mathrm{E}_{\mathrm{BI}} \quad \frac{2 \mathrm{C}_{\mathrm{XiY}}()}{2 \mathrm{C}_{\mathrm{XiY}}()++} \quad \frac{1}{P_{2}}: \tag{16}
\end{equation*}
$$

Evaluating the above expression in the lim it of low tem peratures $<\mathrm{eV}$ and at the symm etric position $\mathrm{x}=\mathrm{y}$, we arrive at the simple form

$$
\begin{equation*}
\frac{\sin ^{2} 2 \# \sin ^{2}(\mathrm{eV}=\mathrm{h}}{2(\mathrm{eV}=\mathrm{h})^{2} \quad \sin ^{2} 2 \# \sin ^{2}(\mathrm{eV}=\mathrm{h})} \quad \mathrm{P}^{1} \frac{1}{2}: \tag{17}
\end{equation*}
$$

W e observe that the violation of the Bell inequality is restricted to short tim es $<{ }_{B I}=\mathrm{v} \quad \mathrm{h}=\mathrm{eV}$ ( (化] the relevance of a coincidence $m$ easurem ent involving the
 the violation strongly depends on the $m$ ixing angle \# of the beam splitter, $w$ ith a $m$ axim al violation realized for a symmetric splitter \# = =4 generating a pure triplet state across the two arm s . T he Bell inequality cannot be violated for asym $m$ etric splitters $w$ ith $\#=4 j>0: 2135$ (corresponding to an angularwidth \# $^{2} 4 \mathrm{j}>12.235$ ): evaluating the BI $\left(\overline{1} \overline{Z_{1}}\right)$ at zero tim e di erence (i.e., in a coincidence $m$ easurem ent) we nd the condition

$$
\begin{equation*}
\frac{\sin ^{2} 2 \#}{2 \sin ^{2} 2 \#} \quad P^{1} \frac{1}{2} ; \tag{18}
\end{equation*}
$$

from which one derives the critical angle $\#_{c}=$ $\left[\arcsin (2=(\overline{2}+1))^{1=2}\right]=2=0: 572$ (or $\#_{C}=32: 765$ ). The appearance of a critical angle naturally follow sfrom the fact that the $m$ easured wave function com ponent ${ }_{u d}^{12}$ assum es the form of a sim ple Slater determ inant in the lim its \# = 0; =2 and hence is not entangled. $N$ ote that the product of average currents + is the largest term in the denom inator of (1] $\left.\overline{1} \bar{\sigma}_{1}\right)$ and hence alw ays relevant.

In conclusion, we have described a m esoscopic setup w ith a source in jecting non-entangled electron pairs into two source leads $s^{\prime}$ and $s^{\prime}$. Subsequent $m$ ixing of these particle stream sin a four-channelbeam splitter does not generate entanglem ent betw een the particles in the two output leads $\mathrm{u}^{\prime}$ and $\mathrm{d}^{\prime}$. H ow ever, properm ixing of the incom ing beam $s$ in the splitter rem oves the inform ation on the path of the incom ing particles and generates a wave function com ponent describing electrons split betw een the leads ' $\mathrm{u}^{\prime}$ and $\mathrm{d}^{\prime}$ which is entangled. It is this com ponent which $m$ anifests itself in the coincidence $m$ easurem ent of a B ell inequality test and proper violation is observed at short tim es. This analysis answ ers the question regarding the origin ofentanglem ent observed in the B ellinequality test applied to the present non-interacting system. A m odi ed setup where the particles propagate dow nstream after a coincidence m easurem ent lends itself as a source for spin-entangled particles, cf. R ef. ${ }_{1} \bar{q}_{1}$.

It is interesting to analyze the setup described in R ef. $\bar{q}$ in the light of the ndings reported here. T he setup in [op] involves sinple nom al reseryoir in jocting pairs of electron'sinto_a source lead which are_subsequently separated in space by a beam splitter. T he in jected pairs reside in a spin-singlet state involving the identical orbital wave function, ${ }_{i n}^{12}=\begin{array}{ccc}1 & 2 & 12 \\ \mathrm{~s} & \mathrm{~s} & \mathrm{sg}\end{array}$; the entanglem ent observed in a B ell inequality test then has been attributed to the entanglem ent associated with this spin-singlet state. O ne
$m$ ay criticise, that this incom ing singlet, being a sim ple Slater determ inant, is not entangled according to the definition given by Schliem ann et al. [111]. H ow ever, after the beam splitter the orbital wave finction $s$ is delocalized betw een the tw o leads, $s!=t_{s u} u+t_{s d} d$, $w$ ith $t_{s u}$ and $t_{s d}$ the corresponding scattering am plitudes. W hile the scattered state rem ains a Slater determ inant
${ }_{\text {out }}^{12}=\begin{array}{lll}1 & 2 & 12 \\ \mathrm{sg}\end{array}$, the singlet correlations now can be observed in a coincidence $m$ easurem ent testing the crosscorrelations between the leads $\mathrm{u}^{\prime}$ and $\mathrm{d}^{\prime}$. Hence the spin-entanglem ent is produced by the reservoir, but its observation requires proper pro jection. It is then di cult to trace a unique origin for the entanglem ent $m$ anifested in the violation of a $B$ ell inequality test. T he appropriate setup to address this question should involve a reservoir in jecting particles w ith opposite spin residing in a Slater determ inant of the form $\quad{ }_{\text {in }}^{12}=\left[\begin{array}{llll}1 & 2 & 1 \\ s^{\prime \prime} & s_{\#} & { }_{2}^{2} & s^{\prime \prime} \\ s^{\prime \prime}\end{array}\right]=\overline{2}$ which is not entangled in the spin variable. Such an analysis has been presented here w ith the result, that the orbitalprojection in the coincidence $m$ easurem ent is su cient to produce a spin-entangled state.
