#### Abstract

W e perform ed path integral sim ulations of spin evolution controlled by the R ashba spin-orbit interaction in the sem iclassical regim e for chaotic and regular quantum dots. T he spin polarization dynam ics have been found to be strikingly di erent from the D'yakonov-P erel' (D P ) spin relaxation in bulk system s. A lso an im portant distinction have been found between long tim e spin evolutions in classically chaotic and regular system S . In the form er case the spin polarization relaxes to zero w ithin relaxation tim em uch larger than the D P relaxation, while in the latter case it evolves to a tim e independent residual value. The quantum $m$ echanical analysis of the spin evolution based on the exact solution of the Schrodinger equation $w$ ith $R$ ashba SO I has con $m$ ed the results of the classical sim ulations for the circular dot, which is expected to be valid in general regular system s . In contrast, the spin relaxation down to zero in chaotic dots contradicts to what have to be expected from quantum $m$ echanics. This signals on importance at long tim of the $m$ esoscopic echo e ect $m$ issed in the sem iclassical sim ulations.

## I IN TRODUCTION

Spin relaxation in sem iconductors is an im portant physical phenom enon being actively studied recently in connection $w$ th various spintronics applications [1] $\overline{1} 1$. In doped bulk sam ples and quantum wells ( Q W) of III-V sem iconductors at low tem peratures spin relaxation is m ostly due to the DP m echanism $[\overline{-1}]$. This m echan ism does not involve any inelastic processes, so that the exponential decay of the spin polarization is determ ined entirely by the spin-orbit interaction (SO I) and elastic scattering of electrons on the im purities. H ow ever, in case of con ned system ssuch asquantum dots (QD) w ith atom ic-like eigenstates, the SO I has been incorporated into the structure of the wave functions of the discrete energy levels. W ithout inelastic interactions, an initial wave packet w ith a given spin polarization w illevolve in tim e as a coherent supenposition of these discrete eigenstates. Therefore, the corresponding expectation value of the spin polarization will oscillate in tim ew thout any decay. To obtain a polarization decay in the QD's, extra e ects have to be introduced into the system, e.g., the inelastic interactions betw een electrons and phonons m ediated by the spin-orbit $\left[\overline{3}_{1}^{\prime}, \overline{4}_{1}^{\prime}\right]$ and nuclear hyper ne e ects $\overline{12}, \overline{1}$ induced by these e ects is a real dephasing process.

Unlike such an inelastic relaxation in $Q D^{\prime}$ 's, the DP spin relaxation in unbounded system $s$ seem $s$ to be a quite di erent phenom enon, because the scattering on im purities is elastic and there is no dephasing of the electron wave functions in the system s. H ow ever, the spin polarization does decay in tim e exponentially, as if it w ould be a true dephasing process. To explain this phenom enon, let us consider an electron $m$ oving di usively through an
unbounded system $w$ ith random elastic scatters. This electron is described by a wave packet represented by a supenposition of continuum eigenstates. D uring a DP relaxation process, the spin expectation value expressed as a bilinear com bination of these wave am plitudes w ill decay exponentially in tim e. This process can be easily understood from the sem iclassicalB oltzm ann or Fokker$P$ lank approach $\overline{1} 1]$. Indeed, keeping in $m$ ind that the SO I has the form $h(k)$, where is the vector, whose com ponents are the three $P$ aulim atrioes, and $h(k)$ is the $e$ ective $m$ agnetic eld, whose $m$ agnitude and direction depend on the electron $m$ om entum $k$, one can envision spin relaxation as the spin random walk on the surface of the unit sphere, sim ilar to that in Fig. 1 (c). Starting at the north pole, the spin precesses around $\mathrm{h}\left(\mathrm{k}_{1}\right)$ until the $m$ om entum direction is changed by a scattering on an im purity. Thereafter, the $m$ agnetic eld changes its direction to $h\left(k_{2}\right)$ and the spin continues its precession around this new direction. If the spin rotation angle betw een successive scattering events is $s m$ all, the sequence of such rotations results in a di usive spreading of the initial polarization.

Retuming to $Q D$ 's, a natural question em erges: what sort ofspin evolution can be generated by the DP $m$ echanism in a ballistic Q $D$ whose size is $m$ uch larger than the electron wavelength at the Ferm i surface and where the $m$ ean spacing betw een energy levels is $m$ uch less than $h=T$, where $T$ is the $m$ ean time betw een electron collisions w ith the boundary? Sim ilar to the exam ple in Fig. 1, the spin evolution in this sem iclassical regim e can be studied by tracking the spin walk on the sphere, when particles $m$ ove along the classical tra jectories inside the QD's. Intuitively, one would expect the spin evolution in this case to be sim ilar to the spin random walk gov-
emed by the im purity scattering in unbounded sam ples. H ow ever, this expected analogy w th the open system is w rong. Indeed, in an unbounded system, the steps of the random walk are uncorrelated. This results in a di usive decay of the spin polarization down to zero for any nonzero SO I.B ut in case ofQD 's, the steps of the random walk on the sphere are correlated due to the con nem ent of electron trajectories within the dots. A s we will show below, such correlations not only lead to a spin relaxation much longer than the DP relaxation in unbounded system $s$, but also to a non-zero nal polarization value at long tim e for certain quantum dot geom etries. H ere, we do not take into account the inelastic $m$ echanism $s$ [1", zero in long time. These $m$ echanism $s$ are assum ed to be absent, because they becom $e$ ine cient at low su ciently tem peratures.

In this article we carry out a sem iclassical analysis of the DP relaxation in 2-dim ensional (2D ) QD's of various geom etries, including a circular dot, a triangular dot, a generalized Sinai billiard, and a circular dot with di usive scattering on the boundary. W e focus on the case of the strong SO I, such that the characteristic spin orbit length $L_{\text {so }} \quad{ }^{W}=h h\left(k_{F}\right)$ is not $m$ uch larger than the dot size L. Such a regim e can be realized in the InA s based heterostructures for $\mathrm{L} \quad 0: 5 \quad 1 \mathrm{~m}$ in the short tim e scale $T$ the spin relaxation dynam ics in all geom etries shares a com $m$ on feature: A fter a fast initialdrop during the tim e interval $T$, the spin polarization continues to oscillate weakly around som e value. Forweak SO Iw th $\mathrm{L}_{\text {so }} \quad \mathrm{L}$, all residualvalues fordi erent dot geom etries are quite close to one up to the cuto tim e ofour num ericalsim ulations ( $10^{3} \mathrm{~T}$ ). For stronger SO I w th $\mathrm{L}_{\text {so }} \quad \mathrm{L}$, the initial drop of the spin polarization is considerably larger com pared to the weak SO I regim e. The spin evolution after that drop depends on the dot geom etry. In the case of circular and triangular dots, which are exam ples ofsystem sw ith regular classical dynam ics, the corresponding spin polarizations approach nonzero residual values. H ow ever, in the case of chaotic and random system s (e.g., Sinaibilliard and circular dot with rough boundaries, respectively), the spin polarizations slow ly decrease to zero after that initial drop. But this decreasing is much longer than the D P relaxation in an unbounded system, in which the $m$ ean im purity scattering time is T. For very strong SOIw ith $\mathrm{I}_{\mathrm{so}}<\mathrm{L}$, the spin polarization after the initial drop reaches zero and later on oscillates w th a large am plitude.

These results clearly dem onstrate that the spin evolution in $Q D$ 's is qualitatively distinct from the DP spin relaxation in unbounded system s . In order to elucidate the physical origin of this phenom enon, two investigations have been perform ed. First, the spin evolution along a single electron trajectory was studied in detail, which provided a chue for understanding the above-m entioned polarization behavior. Second, the residual polariza-
tion obtained from the classicalsim ulations for a circular quantum dot was com pared w ith that derived from the exact solution ofthe Schrodinger equation. A good agree$m$ ent betw een the results from these two approaches has been found. However, for QD's w th chaotic and random electron dynam ics, the generalquantum $m$ echanical analysis revealed a contradiction to the long tim e spin evolution observed in our sem iclassical sim ulations.

The article is organized in the follow ing way. In Section II the general expression of the polarization $w$ ill be derived for the spin evolution via classicalpath integrals. In Section III the results of the num erical sim ulations in di erent quantum dots $w$ ill.be dem onstrated. The quantum $m$ echanical theory for the spin polarization in the circular quantum dot $w$ ill be presented in Section IV, w th the calculation in detail shown in the A ppendix. $D$ iscussion and conclusion will be given in Section $V$.

## II PATH INTEGRALS FOR THESPIN EVOLUTION

The H am iltonian of the system,

$$
\begin{equation*}
\mathrm{H}=\mathrm{H}_{0}+\quad \mathrm{h} \hat{\mathrm{k}} 0 ; \tag{1}
\end{equation*}
$$

consists of the spin independent part $H_{0}$, which is the electron kinetic energy plus the 2D con ning potential $V(r)$, and the spin-orbit interaction. In III-V sem iconductor heterostructures the e ective "m agnetic" eld $h(\hat{k})$ is given by the sum of the $R$ ashba $[\bar{q}]$ and the $D$ resselhaus $[\overline{9}]$ term s . If the z -axis is chosen penpendicular to the heterostructure interface, the $m$ agnetic eld $h_{R}$ contributing to the $R$ ashba term has two com ponents $\left(h_{R}^{X}(\hat{k}) ; h_{R}^{Y}(\hat{k})\right)=\left({ }_{R} \hat{k}_{Y} ;{ }_{R} \hat{k}_{x}\right)$, where $h \hat{k}=$ $\left(h \hat{k}_{x} ; h \hat{k}_{y}\right)$ is the $m$ om entum operator. In the 2D connem ent, them agnetic eld $h_{D}$ contributing to the $D$ resselhaus term contains both linear and cubic parts $w$ ith respect to $\hat{k}\left[\begin{array}{ll}{[10} \\ \hline\end{array}\right]$. In a [001] oriented Q $W$ the linear term has the components $\left(h_{D}^{X}(\widehat{k}) ; h_{D}^{Y}(\hat{k})\right)=\left({ }_{\mathrm{D}} \hat{k}_{\mathrm{x}} ;{ }_{\mathrm{D}} \hat{\mathrm{k}}_{\mathrm{Y}}\right)$. For heterostructures w th a typical 10 nm con nem ent in $z$-direction, the linear part of $h_{D}$ is usually larger than the cubic part, except the case of high doping concentration [11]. The R ashba term is not zero only in heterostructures w ith asym $m$ etry in their grow th direction. $T$ his term can be much larger than the D resselhaus term in the narrow gap InA s based system $s$ [ $\left.\overline{7}_{1}\right]$. In this article we w ill study the spin evolution induced by the $R$ ashba term . But, since the SO I H am iltonians corresponding to the $R$ ashba and the linear $D$ resselhaus term $s$ can be transform eg from one to the other by the unitary $m$ atrix $(x+y)=\overline{2}$, our results are also valid for system $s$ in which the linear D resselhaus term dom inates the SO I.

Let us suppose $E_{n}$ to be the $n$-th quantized energy level w th the eigenfunction ' n , which is a two component spinor. At zero $m$ agnetic eld this quantum state is at
least doubly degenerate. Let

$$
\begin{equation*}
(r)=e^{i k r}(r \quad R) \tag{2}
\end{equation*}
$$

be the wave packet created at time $t=0$, centered at the point R, and propagating w th the 2D wavevector $k$. The function ( $r$ ) is assum ed to be slow ly varying w ithin the scale of the electron k avelength $2=\mathrm{k}$ and norm alized, so that the integral $j(r) j^{2} d^{2} r$ over the QD volum e is equal to 1 . The initial spin polarization $P(0)=\quad$ is the sum over the two com ponents of the spinor, where $2 f 1 ; 2 g$. Fort $>0$, the w ave packet evolves in time as

$$
\begin{equation*}
(r ; t)={ }_{n}^{X} c_{n}^{\prime}{ }_{n}(r) e^{i E_{n} t=h} ; \tag{3}
\end{equation*}
$$

where

$$
c_{\mathrm{n}}=r_{\mathrm{n}}^{\mathrm{y}}(r) \quad(r) d^{2} r:
$$

In term s of $(r ; t)$ the tim e dependent spin polarization is expressed as

$$
\begin{equation*}
P(t)=X^{X^{Z}} \quad(r ; t) \quad(r ; t) d^{2} r ; \tag{5}
\end{equation*}
$$

w ith three com ponents $P^{(t)}=\left(P^{x}(t) ; P^{y}(t) ; P^{z}(t)\right)$.
For further analysis it is convenient to introduce the retarded and advanced $G$ reen functions,

$$
\begin{align*}
& \left.G^{r} \quad \underset{X}{t} \quad \text { lir } ; r^{0}\right)=G^{a} \quad\left(t^{0} \quad t ; r^{0} ; r\right)  \tag{6}\\
& \left.=i_{i}^{X} r_{n}(r)_{n}{ }_{n}\left(r^{0}\right) e^{i E_{n}\left(t t^{0}\right)} \text { ( } \quad t^{0}\right) \text {; }
\end{align*}
$$

which are 22 m atrices acting on the $\mathrm{SU}(2)$ spin space, $w$ here ( $t \quad t^{0}$ ) is the $H$ eaviside function. U sing these G reen functions, the spin-spin correlation function can be de ned as

$$
\begin{align*}
& K_{Z}^{i j}\left(r ; r^{0} ; t \quad l\right)  \tag{7}\\
& =\operatorname{Tr}^{\mathrm{i}} \mathrm{G}^{\mathrm{r}}\left(\mathrm{t} \quad \mathrm{l} ; \mathrm{r}^{\infty} ; r\right)^{\mathrm{j}} \mathrm{G}^{a}\left(\mathrm{t}^{0} \quad \mathrm{t} ; \mathrm{r}^{0} ; r^{\infty}\right) d^{2} r^{\infty} ;
\end{align*}
$$

where i;j 2 fx;y;zg. This de nition together with Eqs. (3ָ1, in $\operatorname{tim} \mathrm{e}$,

$$
\begin{array}{r}
P^{i}(t)=\frac{1}{2}^{Z} K^{i j}\left(r ; r^{0} ; t\right)(r \quad R) \quad\left(r^{0} \quad R\right) \\
\left.e^{i k(r} r^{0}\right) P^{j}(0) d^{2} r d^{2} r^{0}: \tag{8}
\end{array}
$$

For classical sim ulations below, the sem iclassical approxim ation of Eq. ( $\bar{q}$ ) is required. It can be derived from a standard path integral form alism [ $[1 \overline{2} \overline{2}]$, by representing the retarded $G$ reen function in Eq. (17) as the
sum ofproducts,

$$
\begin{align*}
& \mathrm{G}_{\mathrm{Z}}^{\mathrm{r}}\left(\mathrm{t} \quad \mathrm{t}_{\mathrm{e}} ; \mathrm{r}_{\mathrm{r}} \mathrm{r}^{0}\right) \mathrm{X}  \tag{9}\\
& \left.=\quad d r_{1} \quad n \begin{array}{l}
X \\
d r
\end{array} \quad h r ; j^{i H(t)} t_{1}\right) j_{1} ;{ }_{1} i \\
& h r_{1} ;{ }_{1} \dot{j}^{i H\left(t_{1} t_{2}\right)} j_{2} ;{ }_{2} i \quad n \text {; hrje }{ }^{i H\left(t_{n} t^{0}\right)} j^{0} ; i
\end{align*}
$$

ofthe evolution operatorse if ( $t_{i} t_{j}$ ) within the in nitesim ally short time intervals ( $t_{i} \quad t$ ). Thereafter, the $G$ reen fiunction can be expressed as the path integral of $T \exp \frac{i}{h} S\left(t \quad e_{i} r ; r^{0}\right)$, where the action

$$
\begin{align*}
& S\left(t \quad t_{i}^{0} r ; r^{0}\right)  \tag{10}\\
& =\mathrm{t}_{\mathrm{t}^{0}}^{\mathrm{Z}} \frac{\mathrm{~m}}{2} \mathrm{v}^{2}\left(\mathrm { r } \quad \mathrm { V } \left(\mathrm{r}(\mathrm{)}) \quad \mathrm{R} \frac{\mathrm{~m} \mathrm{~V}(\mathrm{)}}{\mathrm{h}}\right.\right.
\end{align*}
$$

is a tim e integral of the particle Lagrangian evaluated along a trajectory starting from $r^{0}$ at time $t^{0}$ and ending $w$ ith $r$ at time $t$, where $v()=\frac{d r}{d}$. In this Lagrangian, the constant term $m \quad{ }_{R}^{2}=2$ is ignored, because it only gives a phase factor. Since the SO I Lagrangians on different parts of the trajectory do not com $m$ ute, one has to keep di erent $\exp \frac{i}{h} S\left(t \quad f_{i} ; r^{0}\right)$ in the order of the sequence in Eq. (d), which is preserved by the tim e ordering operator $T$.

By using the saddle point approxim ation, the path integralin Eq. ( $\bar{q}_{1}^{\prime}$ ) can be reduced to a sum over all classical trajectories [13],

$$
\begin{align*}
& G^{r}\left(t \quad e^{0} ; r ; r^{0}\right)  \tag{11}\\
& =\frac{1}{2} \mathrm{P} \frac{\mathrm{~J}\left(r ; r^{0}\right) \mathrm{e}^{\frac{i}{n}} S_{0}\left(t t^{0} ; r ; r^{0}\right)}{} \mathrm{U}\left(\mathrm{t} \quad \mathrm{e} ; r ; r^{0}\right) ;
\end{align*}
$$

w th the spin independent m onodrom y m atrix $\mathrm{J}\left(r ; r^{0}\right)=$ det $\frac{ब^{2} S_{0}}{@ r_{i} @ r_{j}^{0}}$ and the spin independent classical action $S_{0}\left(t \quad t_{i} r ; r^{0}\right.$ ) along the classical trajectories. The spin dependence part of the $G$ reen function is represented by the unitary $m$ atrix

$$
\begin{equation*}
U\left(t \quad t^{0} ; r r^{0}\right)=T e^{\frac{i}{h}}{ }_{t 0}^{R_{t}} h_{R} \frac{m v()}{h} d: \tag{12}
\end{equation*}
$$

Such a decoupling of the spatial and spin degrees of freedom can be done under the assum ption that the classical paths are only weakly perturbed by SO I, which is reasonable, when the SO I param eter $R$ is $m$ uch less than the electron Ferm i velocity. U nder this assum ption, all quantities $J, S$, and $U$ are evaluated on the unperturbed trajectories.
 tain a sem iclassical expression for the spin polarization. This expression can be substantially sim pli ed after integrating over coordinates $r$ and $r^{0}$ in Eq. (8/1). Indeed, let us consider the integral in Eq. (i),
$Z \mathrm{p} \overline{J\left(r^{\infty} ; r\right)} e^{\frac{i}{h} S_{0}\left(t ; r^{\infty} ; r\right) \quad(r \quad R) e^{i k r} U\left(t ; r^{\infty} ; r\right) d^{2} r:(13), ~}$

In the sem iclassical lim it, the exponential function $\exp \frac{i}{h} S_{0}\left(t ; r^{\infty} ; r\right)$ rapidly oscillates as a function of $r$ w ith a period given by the Ferm i w avelength. H ow ever, $J, U$, and are slow ly varying functions ofr. The length scale of J's variation is given by the dot size. The spatial changes of $U$ are controlled by the spin orbit length $L_{\text {so }}=h=\left(\begin{array}{ll}m & R\end{array}\right)$, which is assum ed to be much larger than the Ferm iwavelength. Therefore, the in uence of the SO I on the saddle-point position can be ignored. T he variation of also can be ignored, because this function was assum ed to change weakly w thin the length scale equal to the electron wavelength. U nder these approxi$m$ ations, we obtain the saddle-point equation in the form

$$
\begin{equation*}
\frac{@ S_{0}\left(t ; r^{\infty} ; r\right)}{@ r}+h k=0: \tag{14}
\end{equation*}
$$

This equation is the classical equation of $m$ otion. It determ ines the trajectory $r=r_{0}\left(r^{\infty}(t) ; p(0)\right)$ which passes through the given point $r^{\infty}(t)$ at the instant $t$, on condition that at $t=0$ the initialm om entum wasp $(0)=h k$. $T$ herefore, the saddle point $r$ is a particle coordinate at $t=0$ belonging to this tra jectory. Since the integralover $r^{0}$ in Eq. (8/') is taken around this extrem um, the value $r^{0}=r=r_{0}$ are inserted into all slow ly varying functions $J, U$ and .

Further, to calculate the integral over $r$ in Eq. [1] $\overline{3}$ ), the action $S_{0}\left(t ; r^{\infty} ; r\right)$ is expanded around $r=r_{0}$ up to the second order,

$$
\begin{align*}
& S_{0}\left(t ; r^{\infty} ; r\right)+h k=S_{0}\left(t ; r^{\infty} ; r_{0}\right) \\
& +\frac{1}{2} \frac{@ S_{0}\left(t ; r^{\infty} ; r_{0}\right)}{@ r_{0}^{i} @ r_{0}^{j}}\left(\begin{array}{lll}
r & r_{0}^{i}
\end{array}\right)\left(\begin{array}{rl}
r & r_{0}^{j}
\end{array}\right): \tag{15}
\end{align*}
$$

The integration over $r$ and $r^{0}$ in Eq. ( $\left.\overline{(B}_{1}\right)$ gives (2 $)^{2}=\operatorname{det} \frac{@ S_{0}\left(t ; r^{00} ; r_{0}\right)}{@ r_{0}^{i} @ r_{0}^{j}}$. Combining this Jacobian with $J\left(r^{\infty} ; r_{0}\right)$ we obtain

$$
\begin{align*}
& \operatorname{det} \frac{@ S_{0}\left(t ; r^{\infty} ; r_{0}\right)}{@ r^{\infty i} @ r_{0}^{j}} \ln \frac{@ S_{0}\left(t ; r^{\infty} ; r_{0}\right)}{@ r_{0}^{i} @ r_{0}^{j}} \#_{1} \\
& =\operatorname{det} \frac{@ r_{0}^{i}}{@ r^{\infty j}}: \tag{16}
\end{align*}
$$

By using the identity

$$
\begin{equation*}
\operatorname{det} \frac{\varrho r_{0}^{i}}{@ r^{00 j}} d^{2} r^{\infty}=d^{2} r_{0} ; \tag{17}
\end{equation*}
$$

Eq. ( $\bar{I}_{1}$ ) can be integrated over $r_{0}$, instead of $r^{\infty}$, which leads to the expression of the sem iclassicalspin polarization,

$$
\begin{equation*}
P_{C}^{i}(t)={\frac{P^{j}(0)}{2}}^{Z} R^{i j}\left(r ; r^{0} ; t\right) j\left(r^{0} \quad R\right) \xi d^{2} r^{0} ; \tag{18}
\end{equation*}
$$

with

$$
\begin{equation*}
\mathrm{R}^{\mathrm{ij}}\left(\mathrm{r} ; \mathrm{r}^{0} ; \mathrm{t}\right)=\operatorname{Tr}{ }^{\mathrm{i}} \mathrm{U}\left(\mathrm{t} ; \mathrm{r} ; \mathrm{r}^{0}\right)^{\mathrm{j}} \mathrm{U}^{\mathrm{y}}\left(\mathrm{t} ; \mathrm{r} ; \mathrm{r}^{0}\right) \quad: \tag{19}
\end{equation*}
$$

Equation ( $\overline{1} \overline{8}$ 인) describes the spin evolution of a particle initially distributed around the point $R \mathrm{w}$ ith the probability density j ( $\left.r^{0} R\right)$ ). Thisparticle starts its classical $m$ otion from the point $r^{0} w$ ith the $m$ om entum $h k$ at tim $e$ zero and arrives in the position $r$ at timet. In the follow ing, we are interested in the spin evolution averaged over an ensem ble of electrons w ith uniform ly distributed coordinates $R$ and random directions of the initial mo$m$ enta on the Ferm i surface. A fter averaging Eq. (1'q) over R and the angular coordinate $k$ of the $m$ om entum k , we obtain the sim ple expression:

$$
\begin{equation*}
P_{c}^{i}(t)={\frac{P^{j}(0)}{4}}^{Z} R^{i j}\left(r ; r^{0} ; t\right) d^{2} r^{0} d_{k}: \tag{20}
\end{equation*}
$$

It should be noted that after the integration over $R$ this expression does not depend on the initial wave packet envelope ( $r$ R ). Therefore, the sam e Eq. (20.) holds for $=$ const, so that the initial state can be sim ply a plane wave.

## III N UMERICALRESULTS

Equation (2 2 ) is the basic equation for our num erical sim ulations of the spin polarization. Below we will restrict ourselves to the case when the initial polarization $P(0)$ is directed along the $z$ axis, so that $P^{z}(0)=1$, and the polarization to be calculated at tim $e t$ is also in z-direction.

## III.1 Spin evolution in ballistic quantum dots

C onsider a free electron con ned inside a quantum dot and $m$ oving along the tra jectory , which consists of the successive straight segm ents $j$ of the lengths $l_{j} w$ ith $j=$ 1, 2, :::; $n$. T he spin state along this tra jectory can be described by the evolution operator $U=U\left(t ; r ; r^{0}\right)$ in Eq. (12) with $t^{0}=0$. $T$ his operator can be represented as a product

$$
\begin{equation*}
\mathrm{U}=\mathrm{U}_{\mathrm{n}} \quad \mathrm{j}^{\mathrm{U}} \quad{ }_{2} \mathrm{UU}_{1} ; \tag{21}
\end{equation*}
$$

of the individual operators

$$
\begin{equation*}
U_{j}=\exp \left[i_{j} J_{j}\right] ; \tag{22}
\end{equation*}
$$

with ${ }_{j}=\frac{l_{j}}{L_{s o}}, J_{j}=N_{j}$. Thereby, $N=n_{j} \quad e_{z}$ is the unit vector parallel to the e ective $m$ agnetic eld $h(k)=R\left(k \quad e_{z}\right)$, where $n_{j}=k=k j$ is the unit vector along the tra jectory segm ent $j$ and $e_{z}$ is the unit vector in $z$-direction. Since $J_{j}$ is a vector in the space of the $P$ aulim atrices, the individual operator in Eq. (22') has a sim ple form

$$
\begin{equation*}
U_{j}=\cos (j) 1 \quad i \sin \left({ }_{j}\right) J_{j} ; \tag{23}
\end{equation*}
$$

w ith the identity m atrix 1 .
Let us assume the $j$-th segm ent $j$ to have the angle $\mathrm{w}_{\mathrm{j}} \mathrm{w}$ ith respect to the x -axis. A ccordingly, the vector $N_{j}$ has the angle $w_{j} \quad=2$, so that we get the explicit expression $J_{j}=\sin \left(w_{j}\right) \times \quad \cos \left(w_{j}\right)$ y. In SU (2) representation, the operator $U{ }_{j}$ can be expressed as the m atrix

$$
U_{j}=\quad \begin{array}{cc}
\cos \left(j^{j}\right) & \sin \left(j_{j}\right) e^{i w_{j}}  \tag{24}\\
\sin \left({ }_{j}\right) e^{i w_{j}} & \cos \left(j_{j}\right)
\end{array}
$$

which acts on the spin state

$$
=\begin{align*}
& 1  \tag{25}\\
& 2
\end{align*}=\cos (=2) e^{i} 1 \quad \sin (=2) e^{i} 2 \quad: ~
$$

In SO (3) representation, the operator $U{ }_{j}$ corresponds to a spin rotation around the axis $N_{j}$ through the angle $2 j$. The three com ponents of the spin expectation value are related to the spinor by

For convenience, we will call the vector projections $s_{i} 2$ [ $1 ; 1$ ] as spin components, although they are tw ice larger than the corresponding values for the spin $1 / 2$.

A s an exam ple ofspin evolution induced by the $R$ ashba interaction, let us consider an electron con ned inside a quantum dot in $F$ ig. 1 (a), moving along the trajectory which consists of three straight segm ents 1,2 , and 3 W th the respective length $l_{1}, l_{2}, l_{3}$ and the angles $\mathrm{w}_{1}==2, \mathrm{w}_{2}=, \mathrm{w}_{3}=3=2$. The initial spin state of this electron is polarized in $z$-direction, which is represented by an arrow in Fig . 1 (c). This arrow is projected dow $n$ to the origin $(0 ; 0)$ on the $s_{x} s_{Y}$ plane in $F i g$. 1 (b). W hen the electron starts itsm otion from the initial point palong the segm ent ${ }_{1}$ ( F ig. 1 (a)), its spin rotates around the axis $N_{1}=(1 ; 0 ; 0)$ and circum scribes an arc on the 3 -dim ensional sphere in $F$ ig. 1 (c). This curve is projected down onto a straight line on the $s_{x} s_{y}$ plane. $T$ his line is parallel to 1 , but runs in a direction opposite to 1 , as shown in Fig. 1 (b). A fter the rst collision $w$ ith the boundary the electron further $m$ oves along the segm ent 2 , while its spin rotates around $\mathrm{N}_{2}=(0 ; 1 ; 0)$ and circum scribes the second arc on the sphere in Fig. 1 (c). The spin projection in Fig. 1 (b) now runs parallel to 2 in the direction opposite to electron $m$ otion along 2. It is easy to see that the spin evolution on other seg$m$ ents follows the sam e rule: W hen an electron passes through the $j$-th segm ent in a certain direction, the spin circum scribes on the 3D unit sphere an arc around the axis $N_{j}$. This arc, in its tum, is pro jected onto the $s_{x} S_{y}$ plane as a straight line parallelto the electron tra jectory, but oppositely directed to it.

Further, let us proceed from the spin evolution on individual trajectories to the spin evolution averaged over

F IG . 1: (C olor online) (a) Electron $m$ otion inside a quantum dot. The trajectory consists of three straight segm ents
1, 2, and 3. (b) The corresponding spin evolution on the $S_{x}$ Sy plane, which is projected from (c). (c) The spin evolution induced by the Rashba spin-orbit interaction on the 3-dim ensional unit sphere.
an ensem ble of trajectories. W e consider an ensem ble of electrons distributed uniform ly within a bounded area of a 2 -dim ensionalheterostructure. At $t=0$ these electrons have random outgoing angles but the sam e spins polarized in $z$-direction. Let $s_{z}^{(\mathrm{i})}(\mathrm{t})$ be the z com ponent of the electron spin at time $t$ for the $i$-th trajectory. Then, in our num erical sim ulations the integral in Eq. (201) can be replaced by the sum,

$$
\begin{equation*}
P_{c}^{z}(t)=\frac{1}{n}_{i=1}^{X^{n}} S_{z}^{(i)}(t) ; \tag{27}
\end{equation*}
$$

where the sum runs over $n$ individual trajectories. The so averaged spin polarization will be calculated in the follow ing ve system $s$ :
(a) In 2-dim ensional bulk (Fig. 2 (a)) w ith the elastic collision length 1 distributed according to the P oisson law $P$ rob $(1)=e^{l=l_{n}}=l_{n n}$, where $l_{n}$ is the $m$ ean free path. It is a stochastic open system. This is just the system where the conventionald 'yakonovPerel' spin relaxation has to be observed.
(b) In a ballistic circular quantum dot of radius 1 w ith the sm ooth boundary in Fig. 2 (b). Since the boundary is sm ooth, the incident and re ection angles on the boundary are the sam e. Since the system is ballistic, no scattering occurs inside the dot. It is an integrable system w ith a high spatial sym $m$ etry.
(c) In a ballistic triangular quantum dot $w$ ith the sm ooth boundary in Fig. 2 (c). It is an integrable system of low er sym $m$ etry com pared to the circular dot.
(d) In a generalized Sinai billiard with the sm ooth boundary in Fig. 2 (d). It is a determ inistic but strongly chaotic system. T he boundary geom etry generates an ergodic dynam ics in the phase space.
(e) In a ballistic circular quantum dot like $F$ ig. 2 (b), but $w$ th random re ections from the boundary. The re ection angle takes random values betw een $=2$ and $=2 \mathrm{w}$ th respect to the boundary norm al. It is a stochastic closed system and corresponds to a quantum dot whose boundary is not perfect in the scale of the electron Ferm iw avelength.

Them ean free path $l_{n}$ in bulk in $F$ ig. $2(a)$ is set to 1. The sizes of the triangular and $S$ inajodots, as show $n$ in Fig. 2 (c) and (d), are chosen to be $\overline{2} \quad 2: 5066$ and $32=(16) \quad 2: 7961$, such that these dots have the same area as that of the circular dot in $F$ ig. 2 (b). W e w illuse the dim ensionless tim e unit, such that during the tim e intervall a particle $m$ oving $w$ th the Ferm ivelocity travels a distance of the length 1 .

## III. 2 R esults of the num erical sim $u$ lations

In $F$ ig. 3 the tim e dependences of $P_{c}^{z}(t)$ for 2124 electrons in the open system ( F ig. 2 (a)) w ith $\mathrm{L}_{\text {so }}=10,6$ and 2 are plotted by solid curves $C_{1}, C_{2}$, and $C_{3}$. O ne can see that the relaxation tim $e$ increases $w$ th $L_{\text {so }}$. These curves can be tted by the well know n expression for the longitudinalD P relaxation [ [13'],

$$
\begin{equation*}
P_{D E}(t)=\exp \frac{4 t_{\text {I }}}{L_{S O}^{2}} ; \tag{28}
\end{equation*}
$$

which is shown by the dashed curves in $F$ ig. 3. This expression was derived under the assum ption of su ciently large $L_{\text {so }} \quad l_{\text {n }}$. For not so large $L_{\text {so }}$ the tting is not good, as it can be seen for the curve $\mathrm{C}_{3}$ around its rst drop at $t=4$. In this regim e the spin rotates rather fast, so that $m$ ost of the spins $s_{z}^{(i)}(t)$ evolve to negative values before the electrons encounter their rst collisions w ith im purities. Therefore, $\mathrm{P}_{c}^{\mathrm{z}}(\mathrm{t})$ can evolve to a deep negative value $w$ ithin a short tim $e$ interval. But later on $P_{c}^{z}(t)$ approaches to the asym ptotic value $P_{c}^{z}=0$ (curve

F IG . 2: (C olor online) Electrons tra jectories (solid lines) for short tim e intervals: (a) in bulk, (b) circular quantum dot, (c) triangular quantum dot, and (d) Sinaiquantum dot.
$C_{3}$ in $F$ ig. 3). These results from $M$ onte $C$ arlo sim ulationscon $m$ thew ell known DP relaxation in unbounded system s.

F IG . 3: Solid curves $C_{1}, C_{2}$, and $C_{3}$ represent the tim e dependent polarization $P_{c}^{z}(t)$ for 2124 particles in an unbounded QW w ith $L_{\text {so }}=10,6,2$ and the $m$ ean free path $l_{n}=1$. The particles were in itially placed inside a circular area of the radius $R=1$ and polarized in $z$-direction. The dashed curves depict the D P relaxation calculated from Eq. (281). For com parison, curve $C_{4}$ show $\operatorname{SP}_{c}^{z}(t)$ for 2124 particles con ned inside a circular dot of the radius $R=1$ and $L_{\text {so }}=10$.

If electrons are con ned inside the sm ooth circular dot ( $F$ ig. 2 (b)), the relaxation of $\mathrm{P}_{\mathrm{c}}^{\mathrm{z}}(\mathrm{t})$ is considerably suppressed, so that at large $L_{\text {so }}$ the spin polarization rem ains
close to 1 at large tim es, as the curve $\mathrm{C}_{4}$ in F ig. 3 dem onstrates for the case of $L_{s o}=10$. At this regim $e$, the suppression of relaxation takes place in all other quantum dots, like the circular dot $w$ ith the rough boundary (curve $\mathrm{C}_{6}$ ), the triangular dot (curve $\mathrm{C}_{7}$ ), and the Sinai billiard (curve $\mathrm{C}_{8}$ ) in F ig. 4. In all of these curves the $P_{c}^{z}(t)$ values fall into the range betw een $0: 97$ and $0: 98$ at large tim es up to $t=10^{3}$.

On the other hand, the spin polarization evolves very fast down to 0 if $L_{\text {so }}$ is sm aller than the dot size. T he corresponding tim e dependence of $P_{c}^{z}(t)$ is sim ilar to that shown in $F$ ig. 3 (curve $C_{3}$ ), with a sharp drop at the beginning followed by oscillations around zero.

F IG . 4: (C olor online) $T$ im e dependence of $P_{c}^{z}(t)$ for $L_{\text {so }}=10$ in the sm ooth circular dot (curve $\mathrm{C}_{5}$ ), the circular dot w ith the rough boundary (curve $\mathrm{C}_{6}$ ), the triangular dot (curve $\mathrm{C}_{7}$ ), and the Sinaibilliard (curve $\mathrm{C}_{8}$ ).

F IG . 5: (C olor online) $T$ im e dependence of $P_{c}^{z}(t)$ for $L_{s o}=2$ in the sm ooth circular dot (curve $\mathrm{C}_{5}$ ), the circular dot $w$ ith the rough boundary (curve $\mathrm{C}_{6}$ ), the triangular dot (curve $\mathrm{C}_{7}$ ), and the Sinaibilliard (curve $\mathrm{C}_{8}$ ).

For an interm ediate $L_{\text {so }}$ the spin relaxes according to di erent scenarios, depending on the quantum dot geom etry. A s an exam ple, $F$ ig. 5 show $s$ the function $P_{c}^{z}(t)$ for various dot geom etries at $L_{\text {so }}=2$. A fter a fast initial drop, the polarization further relaxes to 0 in the Sinai billiard (curve $\mathrm{C}_{8}$ ) and in the circular dot $w$ ith the rough boundary (curve $\mathrm{C}_{6}$ ). However, in the sm ooth circular (curve $\mathrm{C}_{5}$ ) and triangular (curve $\mathrm{C}_{7}$ ) dots this function oscillates around a constant value at large tim es. It should be noted that in the form er tw o exam ples the spin polarization relaxes to zero atm uch longertim es than the DP relaxation time in the unbounded system ( $F$ ig. 3), although the $m$ ean elastic scattering length there is com parable to the dot size. The relaxation tim es for $\mathrm{C}_{6}$ and $\mathrm{C}_{8}$ in F ig. 5 increase rapidly w ith higher $\mathrm{L}_{\text {so }}$. Thus, at $\mathrm{L}_{\text {so }}=10 \mathrm{we}$ could not detect any system atic decrease of the spin polarization in the Sinaibilliard and rough circular dot, up to $t=10^{3}$, which is by an order ofm agnitude larger than the range plotted in $F$ ig. 4.

An interesting feature of $P_{c}^{z}(t)$ in the regular system $s$, like the triangular and sm ooth circular dots, is the apparent oscillation of the polarization. It can be seen at F igs. 4 and 5, although the oscillations in the latter gure are $m$ ore profound for the case of the circular dot, com pared to alm ost vanishing ripples in the triangle. T hese oscillations do not disappear at large tim es and their am plitude increase w ith the strength of SO I. W e can not say much about their nature. P robably, they are associated with the role of periodic trajectories in regular system s. A special study is required to understand the origin and characteristics of these oscillations.

FIG. 6: The residual polarization $P_{c}^{z}$ vs the spin rotation length $L_{\text {so }}$ for a sm ooth circular dot.

At long time the spin polarizations in both regular quantum dots (triangle and sm ooth circle) in Fig. 4 and 5 oscillate around certain nonzero residual values. These residual polarizations $P_{c}^{z}$ are $L_{\text {so }}$ dependent, as plotted in $F$ ig. 6 for the circular dot.
III. 3 Sp in evolution along individualtrajectories

The existence of the nonzero residual polarization in regular quantum dots and long spin relaxation tim e in chaotic system s are fiundam entally distinct from the DP spin relaxation in the boundless $Q W$. Such a distinction is surprising, because at rst sight the spin walks on the sphere in F ig. 1 (c) should be random ized by scattering of particles from dot boundaries, sim ilar to random ization by im purity scattering in unbounded system s. H ow ever, this sim ple point of view is wrong, because there is an im portant di erence betw een the im purity scattering and the boundary scattering. For convenience, let us de ne the scattering with a direction change sm aller than $=2$ as a 'forw ard' scattering and that larger than $=2$ as a 'oackw ard' scattering. If the particles are isotropically scattered by an im purity, half of them continue to $m$ ove 'forw ard'. H ow ever, if the particles are scattered by a sm ooth boundary, the particles w ith incident angles betw een $=4$ to $=4 \mathrm{w}$ th respect to the boundary nom al w illbe re ected 'backw ard'. Since statistically m ore particles hit the boundary within this range of angles, the 'backw ard' scattering prevails in $\mathrm{D} Q$ 's. This property of particle scattering can also be extended to Q D's w ith rough boundaries. Further, according to F ig. 1, a 'back$w$ ard' particle $m$ otion is $m$ apped onto a 'backw ard' spin walk. H ence, if the spin $m$ oves aw ay from the north pole in $F$ ig. 1, after a boundary scattering the spin is $m$ ore likely bounced back tow ards the north pole. Such a non$M$ arkovian statistics of the spin walks gives a clue for understanding the num erical results in subsection III.2.

In order to $m$ ake this argum ent $m$ ore clear it is instructive to study in detail the spin evolution along a single tra jectory. A s described in Fig. 1, the spin $m$ otion on the unit sphere can be pro jected onto the $s_{x} s_{y}$ plane. A fter a long tim e the spin path on the sphere will cover a region and produce a certain pattem on the $s_{x} s_{y}$ plane. In the circular dot th is pattem looks rather ordered. If the electron $m$ oves along a triangular periodic trajectory ( $F$ ig. 7 (a)), the pattem is a rounded triangle ( $F$ ig. 7 (i)). If the trajectories are hexahedral and star-like (F ig. 7 (b) and (c)), the corresponding pattems are a rounded hexagon and a rounded star ( F ig. $7(j)$ and $(k)$ ). If the tra jectories are non-periodic, e.g., Fig. 7 (d), the pattem is a disc ( $F$ ig. 7 (1)). A com $m$ on feature of these pattems is that they have the sam e size, which is less than 1 in the case of $L_{\text {so }}=5$. $T$ hese pattems are highly stable up to the observation tim e $t=10^{4}$. It im plies that the spin on the unit sphere cannot $m$ ove far aw ay from the north pole, so that $s_{z}^{(i)}$ (t) cannot take negative values. O ur analysis of various tra jectories w ith various in itial conditions has con m ed this generalfeature of the spin evolution in the circular dot. H ence, a non-zero $P_{c}^{z}$ in $F$ ig. 6 at in nitely long tim e is obviously expected.

In the triangular dot, two periodic and one non-
periodic tra jectories are shown in Fig. 7 ( $f$ ), ( $g$ ), and (h). The corresponding spin pattems ( $F$ ig. $7(\mathrm{n})$, ( 0 ), and (p)) are less sym $m$ etric and have less predictable sizes than those in the circular dot. For the tra jectory in Fig. $7(\mathrm{~g})$ the pattem in F ig. 7 (o) touches the circular border. $N$ evertheless, our investigation show s that the pattems ofm ost other tra jectories are quite stable up to the observation time $10^{4}$ and do not touch the boarder. On this reason the spin polarization being averaged over trajectories is expected to relax to a positive residual value, although this value is sm aller than that in the sm ooth circular dot.

FIG.7: Electron trajectories on the xy plane ((a)-(h)) and respective spin evolution pattems on the $s_{x} s_{y}$ plane ((i)-(p)) for $L_{s o}=5 .(a)$, (b), and (c) Periodic triangular, hexahedral, and star-like trajectories in the sm ooth circular dot. (d) A non-periodic trajectory in the sm ooth circular dot. (e) A stochastic trajectory in the rough circular dot. ( $f$ ) and ( $g$ ) Two periodic trajectories in the triangular dot. (h) A nonperiodic tra jectory in the triangular dot.

In the circular dot w ith a rough boundary, the re ection angles are stochastic, as show $n$ in $F$ ig. 7 (e). W ithin the observation tim $e t=10^{3}$ the corresponding spin pattem on the $s_{x} s_{y}$ plane has spread out to a much larger area ( $F$ ig. $7(m)$ ) than those in the sm ooth circular dot ( F ig. 7 (i)-(1) ). Furthem ore, the pattem in (Fig. 7 (m)) is still expanding. The corresponding spin state on the 3D sphere can penetrate into the low er hem isphere after $t=10^{3}$. H ow ever, it can retum back to the north sphere again. Therefore, the $z$ com ponent of this spin state oscillates betw een negative and positive values. W hen averaged over $m$ any trajectories, such oscillations sum up to a relaxation curve, sim ilar to $\mathrm{C}_{6}$ in F ig. 5.

In the Sinaibilliard, the $s_{x} s_{y}$ pattem resem bles that in the rough circular dot. C onsequently, the spin relaxation dynam ics in both cases have sim ilar characteristics
(curves $\mathrm{C}_{6}$ and $\mathrm{C}_{8}$ in F ig. 5).
A general trend seen from Fig. 7 is that the con ne$m$ ent of the particle $m$ otion in $Q D$ 's makes the spin to be also con ned within the upper hem isphere, if $L_{\text {so }}$ is larger than the size of the QD's. For a sm ooth circular dot, this trend can be easily understood from the 'backw ard' scattering e ect described at the beginning of this subsection. Since all tra jectories in this case have a sim ple geom etry, one can easily see that particles are $m$ ore frequently scattered from the boundary in a 'backw ard' direction. But although this argum ent holds for general bounded system $s$, it is less evident for other Q D 's besides the $s m$ ooth circular dot. In general case, the trend toward the spin con nem ent can be argued in a di erent way: A s seen from Fig. 1, the projected spin path on the $s_{x} s_{y}$ plane in $F$ ig. 1 (b) is $m$ ore or less a rescaled curve of its particle tra jectory in $F$ ig. 1 (a). But in reality the $m$ apping from a trajectory to the corresponding spin path is not sim ply a rescaling, because the spin rotations on the sphere are non-com $m$ utative. For exam ple, a closed particle trajectory is in generalm apped onto an open spin path. H owever, if $L_{\text {so }}$ is large, the spin path is restricted to a sm all part of the sphere. A ccording to Eq. $\left.\left(2 \overline{1}_{-1}^{+2}\right)^{2}\right)$, a closed particle tra jectory produces an open spin path of the linear size $1=I_{\text {so }}$, while the dis tance betw een the initialand the end points of the path is only $1=\mathrm{I}_{\text {so }}^{2}$. T hem apping betw een the tra jectories and the spin paths is then sim ilar to a m apping betw een two Euclidean spaces. Therefore, w ith the accuracy $1=L_{\text {so }}^{2}$, the spin paths are the rescaled particle tra jectories and those paths are con ned because the particle tra jectories are con ned. It should be noted that such a tendency for the spin con nem ent tums out to be strong even for not so large $L_{\text {so }}$, as one can see from the spin dynam ics shown in $F$ ig. 5 for $L_{\text {so }}=2$.
$T$ he above argum ent about the spin con nem ent does not take into account a long time evolution. Even at large $L_{\text {so }}$, sm all corrections due to non-com mutativity of spin walks will accum ulate in time. As a result, the spin can slow ly drift tow ard the low er hem isphere. The expanding pattem in $F$ ig. $7(m)$ of the rough circular dot is an exam ple of such a long tim e behavior. H ow ever, in contrast to that unstable pattem, the pattems from regular system s (Fig. 7 (i)-(p) besides (m)) rem ain stable in tim $e . T$ his di erence betw een the single tra jectories of random and regular system s is consistent w th the spin relaxation curves show $n$ in $F$ ig. 5.

Such a distinction between regular and chaotic system $s$ follow $s$ from fiundam ental properties of regular and chaotic system s . It can be understood from consideration of periodic onbits. A fter a particle runs along a periodic orbit and completes a period, its in itial spin state w illevolve to U w th $\mathrm{U}=\exp [\mathrm{iR}$ ], which represents a rotation around the axis R through the angle 2 . $B$ oth $R$ and are determ ined entirely by the geom etry of and by the value of $L_{s o}$. A fter the particle repeats $w$
periods, all spin positions ( U$)^{\text {w }}$, corresponding to the end points of all periods $w=1 ; 2$; are located on a closed circle. T his circle can be obtained by rotating the north pole around $R$, if the initial is related to the spin polarized in the north pole direction. The other points on the periodic orbit arem apped onto spin states around this circle. Taking $m$ any periodic onbits into account, one obtains a set ofdi erent axes $R$ and consequently a set of circles passing through the north pole. H ence, when averaged over all periodic onbits, spin spends $m$ ore tim e in the upper hem isphere. This m eans that at least the fam ily of the periodic orbits contributes to a nonzero residual polarization. H ow signi cant is this contribution to the whole residual value depends on the am ount of the periodic orbits in a system, which is quite di erent in regular and chaotic systems. In a regular system the fam ily of periodic orbits has a nitely positive $m$ easure and a bundle of adjacent nearly periodic orbits. These adjacent tra jectories behave like periodic orbits if the time is not too large, because their linear deviation in tim e from the periodic onbits is sm all. On the contrary, the periodic orbits in chaotic system s are of zero $m$ easure [14]. Furtherm ore, their adjacent trajectories deviate from them exponentially fast. T herefore, w ith increasing tim $e$, the weight of the periodic orbits and their adjaœnt trajectories becom es exponentially sm all in chaotic system s , while it is a nonzero value in regular system s. H ence, as long as we consider only periodic orbits, the residual spin polarization has to be a positive num ber for regular system $s$ and zero for chaotic system $s$.

The individual tra jectory study in a larger tim e scale carried out in this subsection helps us to understand som e of the results in subsection III. 2. H ow ever, although the existence of the nonzero residualpolarization $P_{c}^{z}$ is apparent from Figs. 3-6, one cannot exclude a possibility that $P_{c}^{z} w$ ill decay to zero in a much larger tim e scale, since the num erical sim ulations in all these gures are truncated within a nite time. Therefore, we can not de nitely answer the question whether the spin polarization relaxes to zero at the in nitely long time, or to a nonzero residual value. For the sm ooth circular dot the latter altemative is corroborated by an analysis of the spin polarization from the exact solution of the Schrodinger equation, as show $n$ in the next section.

## IV QUANTUM MECHANICALPOLARIZATION IN THECIRCULAR QUANTUM DOT

D ue to the tim e reversal sym $m$ etry, the quantized energy levels $E_{n}$ of the $H$ am iltonian $H$ in $E q$. [1]in) are, at least, tw ofold degenerate $w$ th the corresponding spinor eigenfunctions' na, where a $2 \mathrm{f} g$ is the degeneracy index. In the basis of these states a nom alized w ave func-
tion ( $r ; t$ ) can be expanded as

$$
\begin{equation*}
(r ; t)=C_{n a}^{X} c_{n a}^{\prime} n a(r) e^{i E_{n} t=h} ; \tag{29}
\end{equation*}
$$

with the coe cient

$$
c_{n a}=r_{n a}^{y}(r) \quad(r) d^{2} r:
$$

The expression of $(r ; t)$ in Eq. $\left(2 \overline{2} \bar{q}_{1}\right)$ di ens from Eq. $(\bar{\beta} \bar{\beta})$ only by the degeneracy index $a$, which is explicitly written here for convenience of our further analysis. Taking the notation

$$
\begin{equation*}
\mathrm{na}(\mathrm{r} ; \mathrm{t})=\mathrm{c}_{\mathrm{na}}{ }_{\mathrm{na}}(\mathrm{r}) \mathrm{e}^{\mathrm{iE} E_{\mathrm{n}} \mathrm{t}=\mathrm{h}} ; \tag{31}
\end{equation*}
$$

and $\mathrm{na}(\mathrm{r})=\mathrm{na}(\mathrm{r} ; 0)$, the z com ponent of the quantum $m$ echanical polarization in Eq. (5ַ') can be expressed as

$$
\begin{align*}
& P^{z}(t)=\underset{X}{h}(r ; t) j^{z} j(r ; t) i \\
& =\quad \quad \stackrel{y}{\mathrm{na}}(\mathrm{r})^{\mathrm{z}} \mathrm{nb}^{(r)} \mathrm{d}^{2} r  \tag{32}\\
& \begin{array}{rr}
\mathrm{nab} & Z \\
\mathrm{X} &
\end{array} \\
& +\quad{ }_{n a}^{y}(r)^{z} \underset{m b}{ }(r) e^{i\left(E_{n} \quad E_{m}\right) t=h} d^{2} r: \\
& \text { n } 6 \mathrm{~m} ; \mathrm{ab}
\end{align*}
$$

The rst sum in this equation is time independent, while the second sum oscillates in tim e, so that its average over a su ciently long tim e intervaltums to zero. It is interesting to nd out whether the form er term $\mathrm{co}-$ incides $w$ ith the residual polarization in $F$ ig. 6. Such a coincidence is not evident because the tim e dependent sum can give rise to large variations of $P^{z}(t)$ after long tim e t. M oreover, the sem iclassical theory em ployed in the previous section can be not valid for tim es larger than the $m$ ean distance betw een energy levels near the Ferm i energy. W e can check such a coincidence at least for the sim ple case of a circular dot $w$ th the sm ooth boundary, by calculating the residual polarization

$$
P^{z}=X_{n a a^{0}}^{X} \quad \underset{\mathrm{na}}{\mathrm{y}}(\mathrm{r})^{z} \underset{n a^{0}(r) d^{2} r}{ }
$$

because the analytic solution of the Schrodinger equation w ith the arbitrarily strong $R$ ashba interaction is available [1] ]. In this section only the key steps of the calculation are presented, while the calculation in detail is show n in the A ppendix.

Let us consider a circular quantum dot of radius $R$ w ith the con ning potential

$$
V()=\begin{array}{lll}
0 & \text { for } 0  \tag{34}\\
1 & \text { for } R>
\end{array} \quad \quad \text {; }
$$

w ritten as a function of the polar coordinates $r=r(;)$. $T$ he eigenfunctions of the $n$-th eigenvalue $E_{n}$ are [1]

$$
\prime_{n+}(r)=\quad \begin{gather*}
e^{i} f()  \tag{35}\\
e^{i(+1)} g+1()
\end{gather*}
$$

and

$$
\begin{equation*}
r_{n}(r)=e^{e^{i(+1)} g+1()} \quad e^{i} f() \tag{36}
\end{equation*}
$$

where the function
contains the th order Bessel fiunctions of the rst kind $J$ ( ), the nom alization constant d, the param eters

$$
\begin{equation*}
a=\frac{J(k)}{J\left(k_{+}\right)}=\frac{J+1(k)}{J+1\left(k_{+}\right)} \tag{38}
\end{equation*}
$$

the wave num bers

$$
\begin{equation*}
\mathrm{k}=\frac{\mathrm{p} \overline{\mathrm{~b}^{2}+4^{\prime \prime}}}{2} \text { b } \tag{39}
\end{equation*}
$$

and the index

$$
\begin{equation*}
=\quad 3=2 \quad \mathrm{w} \text { th } \quad=1 ; 2 ; \quad \text { : } \tag{40}
\end{equation*}
$$

Therein, the dim ensionless param eters $==R, "=$ $2 \mathrm{~m} E \mathrm{R}^{2}=h^{2}$, and $b=2 \mathrm{R} \mathrm{m} R=h^{2}$ have been used. The wave num bers $k$ are quantized because the energy levels " are determ ined by the zeros of the function

$$
\begin{equation*}
Z \quad("):=J(k) J+1\left(k_{+}\right)+J\left(k_{+}\right) J+1(k): \tag{41}
\end{equation*}
$$

W e chose the plane w ave

$$
(r)=\begin{align*}
& 1  \tag{42}\\
& 0
\end{align*} e^{i k r}
$$

as the initial state. A fter inserting ${ }^{\prime} n+(r)$ from Eq. (35)
 Eq. (33') and averaging over directions of the vector $k$ we obtain

$$
\begin{equation*}
P^{z}=2^{X} \quad \dot{\zeta}_{n}+\rho \quad \dot{j}_{f} \quad \rho \quad\left(F_{n} \quad G_{n}\right) ; \tag{43}
\end{equation*}
$$

w ith

$$
\begin{align*}
& F_{n}=d^{2}{ }^{h} a^{2} I^{(1)} \quad 2 a I^{(2)}+I^{(3)}{ }^{i} \\
& G_{n}=d^{2} a^{2} I_{+1}^{(1)}+2 a I_{+1}^{(2)}+I_{+1}^{(3)} ; \tag{44}
\end{align*}
$$

where the coe cients $I^{(1)}, I^{(2)}$, and $I^{(3)}$ are presented
 w ritten as

$$
\begin{align*}
& \dot{\operatorname{j}}_{\mathrm{n}} \text { J } \quad=4^{2} \mathrm{~d}^{2} \quad a I^{(4)}+I^{(5)}{ }^{2} \\
& \dot{\mathrm{j}}_{\mathrm{n}} \boldsymbol{J}=4^{2} \mathrm{~d}^{2} \quad \text { a } I_{+1}^{(4)}+I_{+1}^{(5)}{ }^{2} ; \tag{45}
\end{align*}
$$

w th the coe cients $I^{(4)}$ and $I^{(5)}$ given by Eq. (6" ${ }^{(6)}$ ). U sing the dim ensionless units, one has the radius $R={ }^{-} 1$,
the coupling constant $b=2=L_{\text {so }}$, and the $w$ ave num ber $k=2 R=$, where is the electron wavelength. H ence the sem iclassical range of param eters corresponds to $k$ 1.

T he residual polarization calculated from Eq . (4) 4 shown in $F$ ig. 8. The $P^{z}$ curves for $k=20,30$, and 40 are very close to each other and $m$ erge into the dashed curve. This curve coincides with the residual polarization obtained from the sem iclassical sim ulations in the previous section ( $F$ ig. 6). For $k=5,1$, and $0: 1$, the curves are plotted in the dotted, solid, and dash-dotted curves, respectively. A ll the curves, as expected, have the com $m$ on asym ptotic value 1 in the case of the w eak spinorbit coupling $L_{\text {so }}!1$. In the opposite $\lim$ it, $L_{\text {so }}!0$, the behavior of $P^{z}$ is nonanalytic and not $m$ uch revealing. The strong oscillations in this lim it increase with sm aller w ave num bers and signal about the appearance of large quantum beats in $P^{z}(t)$. This regim $e$ of $L_{s o}$ is not interesting from the practical point of view because it im plies unphysically large values of $R$ for the typical dot radius $R=500 \mathrm{~nm}$. In the practically im portant regim e of $L_{\text {so }} \quad 1$ we note an apparent dependence of $P^{z}$ on $k$ at $k$. This is a quantum e ect which is not observed in our sem iclassical sim ulations. In sem iclassics the particle velocity determ ines the speed with which $P^{z}(t)$ approaches to the residual value $P^{z}$, but not this value itself.

F IG . 8: (C olor online) The residual spin polarization $P^{z}$ vs $\mathrm{L}_{\text {so }} \mathrm{w}$ th $\mathrm{k}=20,30,40$, (dashed) $\mathrm{k}=5$ (dotted), $\mathrm{k}=1$ (solid), and $k=0: 1$ (dash-dotted). The dashed curve coincides w ith the curve from F ig. 6.

V D ISCUSSIO N

Sum $m$ arizing the above results of the sem iclassical $M$ onte $C$ arlo sim ulations and quantum $m$ echanical calculations we can draw the follow ing picture of the spin
evolution in sem iclassicalquantum dots. In the dots with regular classical dynam ics the spin polarization does not decay to zero at long tim e and its residualvalue coincides w th the quantum m echanicalspin polarization averaged over an in nitely long tim e interval. At least, we were able to check such a coincidence for the circular dot. O $n$ the other hand, in dots $w$ ith chaotic or random dynam ics the spin polarization relaxes to zero $w$ ith the relaxation time much larger than the DP relaxation time in unbounded quantum wells. Such a decay down to zero can not be understood from the general quantum $m$ echanical expression in Eq. ( $32 z^{2}$ ), because it im plies that the average of $P^{z}(t)$ over an asym ptotically long tim e interval is zero. H ow ever, Eq. (32') predicts that this average is given by the rst term in Eq. (32), which is nonzero in general. Obviously, this contradiction is associated $w$ th quantum mechanical e ects, which indicates that the sem iclassical approxim ation is insu cient for anal ysis of the long time polarization evolution. In disordered $m$ esoscopic system $s$ the statistics of their energy spectrum togetherw ith quantum interference ects give rise to the so called quantum dynam icalecho [1] ${ }^{-1}$ ] which can contribute to the spin evolution at large tim es. This problem needs further study.

The predicted spin evolution can be $m$ easured experim entally. For an InA s dot doped up to $10^{11} \mathrm{~cm}^{2}$, the time unit in Figs. $3-5$ is about 1 ps if the dot size is $\mathrm{L}=0: 5 \mathrm{~m} . \mathrm{H}$ ence, the spin polarization saturates to its residual value during rst 20 ps and for $L_{\mathrm{so}}=1 \mathrm{~m}$ the di erence in the long tim e evolution betw een chaotic and regular dots can be observed in the nanosecond range. In order to suppress allinelastic spin relaxation $m$ echanism $s$
 low tem peratures. The R ashba spin-orbit interaction can be strong in $\operatorname{In} A$ s based heterostructures, $w$ ith $L_{\text {so }}$ dow $n$ to several hundreds nm. M oreover, it can be tuned in a w ide interval by varying the gate voltage [1].

In conclusion, we perform ed path integral sem iclassicalsim ulations ofspin evolution controlled by the R ashba spin-orbit interaction in quantum dots of various shapes. O ur calculations revealed that the spin polarization dynam ics in $Q D$ 's is quite di erent from the D'yakonovPerel spin relaxation in bulk 2D system s. Such a distinction is not expected from the simple picture of the spin random walk, in particular when the rate of electron elastic scattering on im purities in bulk is equal to the $m$ ean frequency of electron scattering from the dot boundaries. W e have also found an im portant distinction betw een long tim e spin evolutions in classically chaotic and regular system $s$. In the form er case the spin polarization relaxes to zero within relaxation time much larger than the DP relaxation, while in the latter case it evolves to a tim e independent residual value. This value decreases w th the stronger spin orbit interaction. We also analyzed the generalquantum m echan icalexpression for the tim e dependent spin polarization. $U$ sing the exact
solutions of the Schrodinger equation w ith R ashba SO I for a circular dot, we calculated the average of the spin polarization over an in nitely long tim e intervaland com pared the result w ith the residual polarization from the $M$ onte $C$ arlo sim ulations. $W$ e found that the residualvalues from these two approaches coincide, which con ms the results from the sem iclassical sim ulations. On this basis, we con jecture that the nonzero residual value is a general property of regular system s. On the other hand, the spin relaxation dow $n$ to zero in the Sinaibilliard and circular dot w th the rough boundary contradicts to w hat have to be expected from quantum $m$ echanics. The long tim em em ory due to the $m$ esoscopic spin echo is assum ed to be responsible for this contradiction.

## A P P E N D IX

$T$ his appendix dem onstrates a quantum $m$ echanical calculation of the residualpolarization $P^{z}$, as it is de ned in Eq. [33]). The calculation of the exact eigenfunctions of the H am iltonian in Eq. (극) for the circular quantum dot can be found in Ref. [161], which is sum $m$ arized in the follow ing Eqs. 4ad

In order to calculate the residual polarization (331), the wave function $n a(r)$ is expanded in the basis of the eigenfunctions given by Eqs. ( 3 3itha $)$. W e note that for a sym $m$ etric presentation, the fiunctions $f$ and $g$ have di erent de nitions from those in Ref. [161. Inserting Eqs. ( 3 3 tion we obtain the equation for $f$ and $g$ in term $s$ of the dim ensionless param eters ;", and b de ned in the previous section,

$$
\begin{align*}
& {[4+\eta] f() \quad b r(+1) g+1()=0 ;} \\
& {[4+1+"] g+1() \quad b r_{+} f()=0 ;} \tag{46}
\end{align*}
$$

w ith the Laplacian

$$
\begin{equation*}
4=\frac{1}{-} \frac{d}{d} \quad \frac{d}{d} \quad \frac{2}{2} \tag{47}
\end{equation*}
$$

and the nabla operator

$$
\begin{equation*}
r=\frac{d}{d} \quad-: \tag{48}
\end{equation*}
$$

The solutions ( $f()$; $g()$ ) of these equations are
w ith the norm alization constant $d$, the factors a given by Eq. ( $3 \overline{3}$ í), and the wave vectors $k$ from Eq. ( $\overline{3} \overline{9})_{1}$. $T$ hese wave vectors obey the relations

$$
\begin{align*}
& \mathrm{k}_{+} \mathrm{k}=\mathrm{k} ; \mathrm{k}_{+} \mathrm{p} \frac{\mathrm{k}=\mathrm{b} ;}{\mathrm{b}^{2}+4 ":}  \tag{50}\\
& \text { and } \mathrm{k}_{+}+\mathrm{k}=
\end{align*}
$$

The quantized dim ensionless energies " are determ ined by the zeros of the function in Eq. (4)른). This function stem $s$ from the determ inant of the equation system in Eq. (4-6) $w$ th the boundary conditions $f()=g()=0$ at
$=1$. G iven a coupling constant b , the n -th quantized value " n w th $\mathrm{n}=\mathrm{n}(;)$ is determ ined by the -th zero of $Z$ ("), where and are related by Eq. ${ }^{\prime}(\overline{4}(\bar{\phi})$. The allow ed wave num bers $k$ are given by Eq. (3d)w ith " = " $n$. They correspond to the two degenerate eigenstates of the $n$-th energy level. The rst root of the function Z (") is zero for $=1=2 ; 3=2$;:: and is a positive value for $=1=2($ see $F i g .9)$. T he larger the value of $b$, the larger the second root of Z (").

F IG . 9: The function $Z \quad(")$ for $=1=2,1=2$, and $3=2$. $T$ his function is singular at " $=0$ for $=1=2$.

Substituting the wave functions in Eqs. ( 3 3nting into Eq. (33) we obtain the residual polarization in the form

$$
\begin{align*}
& +2 c_{n} C_{n} f() g_{+1}() e^{i(2+1)} \\
& +2 c_{n} c_{n}+f() g+1() e^{i(2+1)^{i}} d \quad d: \tag{51}
\end{align*}
$$

For the in itial wave function given by Eq. (4) $4 \overline{2}$ ), the constants $\mathrm{C}_{\mathrm{n}}$ can be expressed as

$$
\begin{align*}
& =\quad r_{n+}^{(1)}(r) e^{i k r} d^{2} r \\
& Z_{2} Z_{1} \\
& \left.=0_{0} e^{i \mathbb{k} \cos ( }\right) \quad \ddagger() d d \text {; } \tag{52}
\end{align*}
$$

$w$ here and stand for the angles of the vectors $r$ and $k$ w ith respect to the positive x -axis and $\mathrm{k}=\mathrm{k} j$. A fter the shiff of the angular variable from to the above integral transform $s$ to

$$
\begin{equation*}
C_{n+}=e^{i} \int_{0}^{Z_{2}} Z_{1} e^{i \mathbb{k}} \cos () \quad \mathrm{f}() \quad d \quad d: \tag{53}
\end{equation*}
$$

Substituting $t=+=2$ and $m=$ into the integral representation of the $B$ essel function [ [1] ],

$$
\begin{equation*}
J_{m}(z)=\frac{1}{2}^{Z} \quad e^{i[z \sin (t) m t]} d t ; \tag{54}
\end{equation*}
$$

we obtain

$$
\begin{equation*}
2 e^{i}=2 J(z)=Z_{0}^{Z_{2}} e^{i[z \cos ()} \quad \text { dd }: \tag{55}
\end{equation*}
$$

By using this identity, Eq. (53) can be written as

$$
\begin{equation*}
C_{n+}=2 e^{i}(=2)_{0}^{Z} J(k) f() d: \tag{56}
\end{equation*}
$$

By analogy, one has

A fter integrating Eq. (51~1) over and the direction of $k$ (integration over is sim ilar to that over $k$ in Eq.
 only the rst term rem ains. Introducing the param eters

$$
\begin{equation*}
F_{n}=Z_{0}^{Z_{1}} f^{2}() d \quad \text { and } \quad G=Z_{0}^{Z_{1}} g_{+1}^{2}() d \text {; } \tag{58}
\end{equation*}
$$

the nal expression for the residual polarization can be w ritten as

$$
\begin{equation*}
P^{z}=\frac{P}{p n} \dot{j}_{n}+\mathcal{\jmath} \quad \dot{j_{n}} \quad \mathcal{f}\left(F_{n} \quad G_{n}\right), \tag{59}
\end{equation*}
$$

For num erical calculations we explicitly w rote the norm of the nom alized w ave fiunction $(r ; t)$ in the denom inator. In this form the expression in Eq. ( $5 \mathbf{5}_{1}^{\prime}$ ) is also valid for non-norm alized w ave functions, because the norm alization constants $d$ in the num erator and denom inator are canceled w th each other.
$T$ he polarization $P^{z}$ in Eq. (50 ${ }^{-1}$ ) is determ ined by the four integrals $\mathrm{C}_{\mathrm{n}}, \mathrm{F}_{\mathrm{n}}$, and $\mathrm{G}_{\mathrm{n}}$. They can be calculated by using the form ula [1d]

$$
\begin{align*}
& Z_{1} \\
& J(\quad) J(\quad) d  \tag{60}\\
& 0 \\
& =\frac{1[J(1) J+1(1) \quad J(1) J+1(1)]}{2}:
\end{align*}
$$

C onsequently, the integrals in Eq. (50) can be written in the closed form

$$
\begin{align*}
& F_{n}=d^{2}{ }^{h} a^{2} I^{(1)} \quad 2 a I^{(2)}+I^{(3)^{i}} ;  \tag{61}\\
& G_{n}=d^{2} a^{2} I_{+1}^{(1)}+2 a I_{+1}^{(2)}+I_{+1}^{(3)} ; \tag{62}
\end{align*}
$$

w ith

$$
\begin{align*}
& I^{(1)}=\frac{J\left(k_{+}\right)^{2}+J+1\left(k_{+}\right)^{2}}{2} \frac{J\left(k_{+}\right) J+1\left(k_{+}\right)}{k_{+}} ; \\
& I^{(2)}=\frac{k J\left(k_{+}\right) J+1(k)}{k^{2}} k_{+} k_{+}^{2}(k) J+1\left(k_{+}\right) \\
& I^{(3)}=\frac{J(k)^{2}+J+1(k)^{2}}{2} \frac{J(k) J+1(k)}{k}: \tag{63}
\end{align*}
$$

By analogy, calculating the integrals in Eqs. $\left.\left(56-5{ }^{-}\right]_{1}\right)$ we obtain

$$
\begin{array}{ll}
\dot{\jmath}_{n}+\mathcal{J}=4^{2} d^{2} & a I^{(4)}+I^{(5)}{ }^{2} ; \\
\dot{\jmath}_{n} f=4^{2} d^{2} & \text { a } I_{+1}^{(4)}+I_{+1}^{(5)}{ }^{2} ; \tag{65}
\end{array}
$$

with

$$
\begin{align*}
& I^{(4)}=\frac{k_{+} J(k) J+1\left(k_{+}\right) k J\left(k_{+}\right) J+1(k)}{k_{+}^{2}} ; \\
& I^{(5)}=\frac{k J(k) J{ }_{+1}(k) k J(k) J{ }_{+1}(k)}{k^{2}}: \tag{66}
\end{align*}
$$

Forsm allb the spin polarization approaches to $P^{z}=1$, as it $m$ ust be in the absence of the spin-orbit interaction. It follow $s$ from the relation $k \quad k_{4}=b \quad 0$ in Eq. ${ }^{2}(5, b)$, which results in $f() \quad 0$, according to the de nition
 which contain $f()$, vanish in $P^{z}$. Therefore, the sum $s$ in the num erator and denom inator of $P^{z}$ becom $e$ the sam $e$, which gives rise to $P^{z}=1$.

For large $b$, we have $P^{z}!0$, which is due to the large di erence betw een $\mathrm{k}_{+}$and k , nam ely, $\mathrm{k}_{\mathrm{C}} \quad \mathrm{k}_{+}=\mathrm{b} \quad 1$. A ccording to the asym ptotic behavior [1d]

$$
\begin{equation*}
J(x)=\frac{r}{\frac{2}{x}} \cos x \quad-\quad+\frac{1}{2}+0 \frac{1}{x} \tag{67}
\end{equation*}
$$

of the Bessel function at large $x$, the $m$ agnitude of the oscillating function $J\left(k_{+}\right)$is much larger than $J(k)$ by the order of $\overline{k=k_{+}}$. Therefore, the leading term $s$ of $I^{(4)}$ and $I^{(5)}$ in Eq. ( 6

$$
\begin{array}{ll}
I^{(4)} & \frac{J\left(k_{+}\right) J+1(k)}{k} ; \\
I^{(5)} & \frac{J(k) J+1(k)}{k}: \tag{68}
\end{array}
$$

The rst term is much larger than the second one. C onsequently, both $C_{n}$ and $C_{n}$ are dom inated by $I^{(4)}$ and have the sam e lim it for large b. By analogy, $\mathrm{F}_{\mathrm{n}}$ and $\mathrm{G}_{\mathrm{n}}$ also have the sam e lim it. Therefore, both $\dot{j}_{n}+\begin{aligned} & f \\ & j_{f}\end{aligned}$ and $F_{n} \quad G_{n}$ in the num erator of Eq . (50 $\mathrm{S}_{1}$ ) becom e sm all and hence $P^{z}=0$ forb! 1 .
