¹Theoretische Physik, ETH-Honggerberg, CH-8093 Zurich, Switzerland (D ated: M arch 22, 2024)

M etallic K $_{3}C_{60}$ shows pronounced structure and a sharp Ferm i edge in integrated photoen ission spectra (PES) while the insulating K $_{4}C_{60}$ and K $_{6}C_{60}$ phases display only a broad structureless peak. We not that both types of spectra can be explained by the coupling to the optic vibrations of the K $^{+}/C_{60}^{n}$ ionic lattice. This is suppressed in K $_{3}C_{60}$ due to m etallic screening but is strong in the insulating phases. We use the non-crossing approximation to calculate the density of states (D O S) of electrons in K $_{3}C_{60}$ coupled to the intram olecular H $_{g}$ m odes in good agreement with the experiment. For K $_{4}C_{60}$ and K $_{6}C_{60}$ strong coupling to the low energy optic K $^{+}/C_{60}^{n}$ m odes controls the D O S and yields broad peaks in the PES. A moment expansion is used to calculate the position and width of these peaks which agree well with the experiment.

PACS num bers: 63.20 K r, 73.61 W p, 79.60 Fr

A Ikalim etal-doped C 60 has been investigated extensively by photoem ission spectroscopy (PES) in bulk systems (Ref. 1, 2, 3 and references therein). Recently, Yang et al. measured the electronic band dispersion of K₃C₆₀ in a monolayer system on Ag(111) by angle resolved PES (ARPES) [4]. By comparing angle integrated spectra (A IPES) from several experiments a generic feature emerges which is the striking dierence between the spectra of metallic K₃C₆₀ and the insulating K_4C_{60} and K_6C_{60} (the form er is a Jahn-Teller distorted insulator, the latter a band insulator): $K_{3}C_{60}$ shows a metallic spectra with a sharp Ferm i edge and distinct structures whereas the insulating phases display a broad Gaussian-peak. In the present work we address this difference. The key ingredient is the large change in coupling strength of the low-energy (! 10 m eV) optic vibrations of the K⁺ ions. These modes cause a net shift of the C₆₀ molecular levels and their interaction is e ciently screened in metallic K₃C₆₀ where it is reduced by a factor 10 4 10 2 [5, 6]. However, in the insulating phases, where m etallic screening is absent, they couple strongly (g 70 m eV, see below) due to the direct Coulom b interaction of the ionic charge with the photoem ission hole. The resulting physics is best illustrated by the toy-model H = $! a^{y}a + gc^{y}c(a^{y} + a)$ where a single electron is coupled to a harm onic oscillator. The corresponding photoem ission spectrum is a Poisson distribution P () = $n^{n} e = n! (+ [n]!) where = (g=!^{2})$ is the average number of excited phonons em itted during the photoem ission process. In the insulating phases

is very large (50) and as a result the spectrum becom es incoherent resulting in a Gaussian-like shape. In the following we treat the metallic and insulating phases separately. First, using the non-crossing approximation (NCA), it is shown that the spectrum of metallic K $_{3}C_{60}$ is dominated by the coupling to the intram olecular C $_{60}$ modes. Second, we use moment expansion to calculate position and width of the Gaussian-like spectra of K $_{4}C_{60}$ and K $_6$ C $_{60}$.

The only modes that couple strongly (1) in K $_{3}C_{60}$ are the intram olecular H $_{g}$ modes which cause a splitting of the threefold degenerate LUM O's of C $_{60}$ (See R ef. 7 for m ore details). We treat these modes by NCA [8] and neglect the on-site C oulomb interaction (U 1 eV in bulk). This is justimed in a monolayer adsorbed on Ag(111) where U is reduced by the proximity of the metal [9]. Here we restrict our attention to such system s. A similar calculation was performed by Liechtenstein et al. who showed that the width of the plasm on in K $_{3}C_{60}$ can be explained by electron-phonon coupling [10]. The Ham iltonian which describes the conduction band of K $_{3}C_{60}$ coupled to the H $_{g}$ modes is (setting ~ = 1)

$$H_{H_{g} vib} = \begin{array}{c} X & X \\ t_{nm} () c_{j+m}^{y} c_{jn} + ! a_{jk}^{y} a_{jk} + \\ & X & h \\ g c_{jm}^{y} c_{jn} C_{nm}^{k} a_{jk}^{y} + C_{mn}^{k} a_{jk} : (1) \\ & & \\ \end{array}$$

The rst term is the tight-binding band in standard notation form ed by the 3-fold degenerate (t_{1u}) LUM O 's of C_{60} . The sum is over the orbitals n and m, the lattice sites j and the nearest neighbors . As the spin orientation is preserved in the Ham iltonian, explicit sum s over spins are dropped throughout. The second term is the energy ! of the eight ve-fold degenerate Hg vibrationalmultiplets [7]. The indices and k denote the multiplet and the mode respectively. The last term describes the electron-phonon coupling. The phonon energies ! and the coupling parameters g are dispersionless. The parameters g are related to the parby $g^2 = \frac{3}{2}!$ tial coupling constant =N (0) where N (0) is the density of states per spin and molecule [11]. Values for ! and where taken from Ref. 12. The structure of the coupling is given by the coe cients $\frac{3}{5}$ (1)^m h2;kj1; m;1;ni where h:::i is the $C_{nm}^{k} =$ Clebsch-Gordan coe cient [13]. The normalization is

such that $P_{knm} C_{nm}^{k}^{2} = 3$. In the NCA, the electron self-energy is determ ined self-consistently by the lowest order self-energy diagram with the interacting G reen's function. In the present problem the Green's function G_{nm} (!;k) and self-energy $_{nm}$ (!;k) are 3 3 m atrices. The free phonon propagator $D_{k}^{0}(!;q) = D^{0}(!)$ depends only on frequency and the multiplet. As a consequence, only the local part of the G reen's function $G_{nm}^{loc} = 1=N$ $_{k}$ G_{nm} (!; k) enters which renders the self-energy $_{nm}$ (!;k) = $_{nm}$ (!) local as well. This is a consequence of including only non-crossing diagram s. The evaluation of the basic diagram can be simplied further when the symmetry of the lattice is used. The m om entum -independent G reen's function $G_{\,n\,m}^{\,\rm loc}$ and selfenergy \lim_{nm} have to be invariant under all symmetry transform ations which belong to the point-group of the lattice. In particular, in a cubic environment (such as a fcc lattice)

$$G_{nm}^{loc}(!) = \hat{G}^{loc}(!)_{nm}; \quad nm(!) = (!)_{nm}; (2)$$

where $\hat{G}^{\text{loc}}(!)$ and $\hat{(!)}$ are scalars. On the surface or in a monolayer the symmetry is lower than cubic and the G reen's function has additional o -diagonal parts. However, the corresponding corrections were found to be small (1 % or less) and therefore it is an excellent approximation to use the G reen's function and self-energy as given in (2). This yields the scalar equation

^ (E) =
$$i g^2 \frac{d!}{2} D_0 (!) \hat{G}^{loc} (E !)$$
: (3)

Thus, the problem is simplified to a single band interacting with a discrete set of phonon modes. Relation (3), which is an equation for the self-energy, is solved iteratively using the advanced G reen's function. In (3), the band-structure only enters via the density of states (DOS) and we chose a generic square DOS with a width $W = 0.5 \text{ eV} \cdot U$ sing other bare DOS revealed that the interacting DOS depends only weakly on the form of the bare DOS. The result for half-lling (= 0), which corresponds to K₃C₆₀, is shown in Fig. 1. The interacting DOS shows an overall structure, such as a dip at 0.2 eV and a second hum p at 0.4 eV, which agrees well with the A IPES of the monolayer system [4].

The insulating com pounds K $_4C_{60}$ and K $_6C_{60}$ di er im – portantly from K $_3C_{60}$. As discussed in the introduction, in the absence of metallic screening, the coupling to the K⁺ modes is strong and the ground state of a hole created by photoem ission will be polaronic. This type of physics is not captured by NCA. On the other hand, the ground states of the insulating phases are rather simple: K $_6C_{60}$ is a trivial band insulator, whereas in K $_4C_{60}$ there are four localized electrons on each C $_{60}$ which form a singlet due to Jahn-Teller distortions [13, 19] R fithe ground state j $_0$ i is known, the moments $_k = d^{-k}P()$ of

TABLE I: Frequencies and coupling constants for the vibrationalm odes in K $_{\rm n}$ C $_{60}$ (all energies are in meV).Parameters for the intram olecular H $_{\rm g}$ and A $_{\rm g}$ modes were taken from R ef. 12. The coupling constant for the lattice vibrations were calculated in this work. In K $_3$ C $_{60}$ the coupling to the A $_{\rm g}$ m odes and the vibrations of the ionic lattice is e ciently suppressed by m etallic screening. a) applies for K $_4$ C $_{60}$.

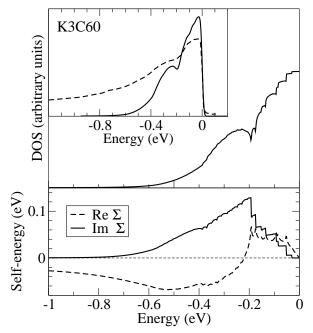

FIG.1: Solution of the NCA at half lling (= 0) which corresponds to K₃C₆₀. Upper panel: Occupied part of the interacting DOS.Lower panel: A dvanced self-energy. Inset: Occupied DOS (solid line) convoluted with a Gaussian (= 10 m eV) and com pared to the experimental spectrum of the m onolayer (dashed line) [4].

the spectrum P () (norm alized to 1) can exactly be calculated by evaluating the expectation values

$$_{k} = \frac{1}{N} \frac{X}{_{jn}} h_{0} j c_{jn}^{Y} [[c_{jn}; H]; H]; H] \dots]j_{0} i: \qquad (4)$$

The sum is over all sites j and orbitals n and N is the total number of the electrons. H is the full H am iltonian and includes all vibrationalm odes as wellas C oulom b in-

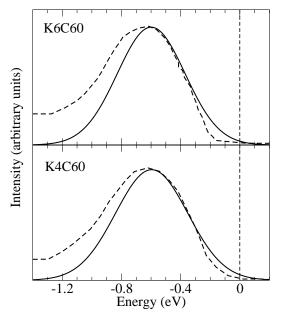

FIG. 2: Gaussian t (solid curves) to the photoem ission spectrum using the rst and second moment as calculated in (4) and plotted with respect to the chem ical potential. The dashed curves are the experimental data (Ref. 2 for K $_6C_{60}$, Ref. 3 for K $_4C_{60}$)

teractions. A lthough relation (4) is exact, the reconstruction of a distribution from a nite number of known moments is an ill-de ned problem if the overall shape of the distribution is unknown. However, as was argued above, the strong coupling to the low -energy optic modes yields a very incoherent, and therefore G aussian-like spectrum. Hence, for this physical reason the distribution should be well approximated by a G aussian which is determined by the rst and second moment as given by (4). The procedure which follows is, rst, to determine all contributions to H and, second, calculate the moments by (4).

The additional phonon contributions to H are modes which cause a net shift of the molecular orbitals and therefore are no longer screened in the insulating phases [5, 6]. These modes are the intram olecular A_q m odes and the vibrations of the ionic lattice. In principle, lattice vibrations also couple via a change in hopping, but the corresponding coupling is much smaller [7]. In the case of the two intram olecular $A_{\rm q}$, the frequencies ! and coupling parameters g are dispersionless. As for the H_q m odes, the latter is given by $g^2 = \frac{3}{2}!$ =N (0) (see above) and values were taken from Ref. 12. The coupling to the ionic lattice has been studied much less extensively, mainly because it is negligible in the superconducting K₃C₆₀. Here we consider the coupling due to the Coulomb interaction between the ionic charges. The mass ratio $M_{C_{60}} = M_K = 18.4$ is big which allows to separate the lattice vibrations into optic dispersionless K -m odes and acoustic m odes. The frequencies of these modes were measured by EELS [14] where it was

observed that K⁺ ions close to the surface have substantially lower frequencies. As photoem ission is surface sensitive, we use these values which are $!_{\rm K} = 8.9 \,\text{meV}$ and $!_{\rm K} = 10.9 \,\text{meV}$ for K₄C₆₀ and K₆C₆₀ respectively. In what follows, only the averaged coupling constant $q_{\rm K}^2 = N_{\rm s}^{-1} q_{\rm s} g_{\rm q} f$ enters (the sum is over all optic K-modes) which is given by (with ~ exceptionally included)

$$q_{\rm K}^2 = \frac{e^2 \sim}{2M_{\rm K}!_{\rm K}} \frac{X}{{}_{\rm r2\,fK^+g}} E_{\rm r}^2:$$
(5)

The sum runs over all K^+ ions r and E_r is the electric

eld at the positions r and caused by an additional hole on the C $_{60}$ m olecule at the origin. The sum in (5) depends on the lattice. K₆C₆₀ has a bcc lattice with a cubic lattice constant a = 11:39 A where each C₆₀ m olecule is surrounded by 24 K⁺ ions located at (0;0:5;0:25)a [16]. Considering the bare coupling of the closest by ${\rm K}^+$ ions yields $g_K = 120 \text{ m eV}$. Taking into account the polarizability of the C_{60}^{6} ions by multipole expansion [17] reduces the electric elds entering (5) by 40 % and yields a coupling constant $g_K = 72 \text{ meV}$. In K $_4C_{60}$ distances between C $_{60}^4$ and K $^+$ are alm ost the same as in K $_6$ C $_{60}$, how ever, every C_{60}^4 ion is surrounded by 16 K⁺ ions instead of 24. This reduces g_{K} in $K_{4}C_{60}$ by a factor 2=3 with respect to K₆C₆₀. Taking also into account the difference in $!_{K}$ we nd $q_{k} = 65 \text{ meV}$ for $K_{4}C_{60}$. Coupling to the acoustic modes is more involved because both ! q and g_q are q dependent. W e used a simple spring m odel param etrized by a phonon frequency of 5 m eV at the B rillouin zone boundary [18]. This yields an averaged coupling constant $g_i = 10 \text{ meV}$. In addition we dan average frequency $i_a = N_s^{1} q_{q} q_{q} = q_{f}^{2} = 3.8 \text{ meV}$. Finally, the Coulom b interactions should also be included in H. However, they vanish in the case of K₆C₆₀ where a single hole is created in a full band. In K_4C_{60} there is a contribution from the on-site Hunds-rule coupling term which involves an exchange energy K = 50 meV (see Ref. 20 for a detailed description). This term leads to an additional increase of the width of the K $_4C_{60}$ spectrum .

In the following wew ill discuss the results for K₆C₆₀ in m ore detail than those of K $_4$ C $_{60}$ because the ground state of the latter involves Jahn-Teller distorted m olecules and a detailed discussion would go beyond the scope of this letter. As m entioned above, the ground state of K $_6C_{60}$ _{jn} c^y jvaci. is a full band and trivially given by $j_0 i =$ Note that j₀i doesn't have any phonon excitations. Coulomb terms can be neglected for $K_{\,6}C_{\,60}$ and the Ham iltonian H = H $_{kin}$ + H $_{p}$ + H $_{ep}$ consists of the kinetic energy, the phonon energies and the electron-phonon coupling terms. As in the previous section we assume a quadratic bare DOS $_0$ with a width W = 0.5 eV and centered around zero. Using relation (4) to evaluate the moments of the photoem ission spectrum one nds that $_1 = 0$. The second moment is $_2 = _2(_0) +$ $_{x} g_{x}^{2}$

where $_{2}(_{0}) = W = (2 \ \overline{3})$ is the second moments of the normalized square DOS $_{0}$. The sum is over all phonon modes x. Similarly, the third moment is $_{3} = _{x} w_{x} g_{x}$. Using the parameters as listed in Tab. I one nds $= \frac{P}{2} = 0.229 \text{ eV}$ and $_{3} = ^{3} = 0.319$. U sually, the photoem ission spectrum is plotted with respect to the chemical potential which, per de nition, is $= E_{0}(N) = E_{0}(N-1) = E_{0}(N-1)$ and therefore corresponds to the polaron ground state energy. In the sm all polaron lim it, where the hole is localized on a single molecule, the chemical potential is given by the relaxation energy of the phonon degrees of freedom which couple to the hole:

$$= E_0 (C_{60}^1) + \frac{q_1^2}{!_K} + \frac{q_2^2}{!_a} = 0.599 \text{ eV}; \quad (6)$$

E $_0$ (C $^1_{60}$) is the Jahn-T eller ground state energy of an electron in the LUM O of an isolated C 60 m olecule interacting with the intram olecularm odes. By particle-hole symmetry, this is the same as E $_0$ (C $_{60}^5$) and was calculated numerically in Ref. 19. The last two terms are the energy gain due to the ionic lattice distortions. It must be noted that the total contribution of the K-m odes to the chemical potential is proportional to $w_{K}^{\ 2}$, because g_{K}^{2} itself is proportional to w_{K}^{1} (relation (5)). Hence, depends sensitively on $!_{K}$. Note that this estimate is a lower bound for the chem ical potential, because in the insulating K $_{6}C_{60}$ it may lay everywhere in the bandgap rather than on the top of the led band. In Fig. 2 a Gaussian of width and shifted by is plotted. The result com pares well with the experimental curve from bulk measurem ents although the width is som ew hat too sm all [2]. O ther thing functions which accounted correctly for the non-zero third m om ent were tested as well which, how ever, yielded only slightly di erent curves than the G aussian shown here.

The case of K $_4C_{60}$ is more complicated, due to Jahn-Teller distorted molecules where the three-fold degenerate LUMO is split into a singlet and a doublet. In K₄C₆₀ the doublet is lower in energy and occupied by four electrons. Hence, they form a fullband in the solid which results in the insulating state. The problem of the Jahn-Teller distortion in C 60, which cannot be solved analytically, has been extensively studied by various approaches [13, 19]. In addition, we developed a variational wavefunction for C_{60}^4 which yields a ground state energy in agreem ent with exact diagonalization results [19]. In order to calculate the expectation values in (4) we use this variational ground state (details of the calculation of the will be published elsew here). We nda rst moment $_1 = 0.174 \text{ eV}$ which is due to the energy gain of the Jahn-Teller distortion. The chem ical potential is again

given by (6), except that $E_0(C_{60}^1)$ has to be replaced by $E_0(C_{60}^4)$ $E_0(C_{60}^3)$ which yields = 0.422 eV [19]. Finally, the second moment is = p - 2 = 0.244 eVwhich is almost the same as in K_6C_{60} . In Fig. 2 the corresponding G aussian is plotted and compared to the experimental data from bulk measurements [3]. Again, good agreement is found.

In conclusion, we showed that the di erent photoem ission spectra in m etallic and insulating K $_{\rm n}$ C $_{60}$ are due to a large change in the coupling strength to the low energy, optic K $^+$ m odes. Theoretical calculations for both cases yield good results.

W e are gratefulto E.K och and O.G unnarsson for useful discussions and, especially, to Z.-X. Shen for drawing our attention to this problem as wellas to W.L.Yang for providing the experimental data. We also acknow ledge the support from the Sw iss N ationalfonds.
