(Dated: March 22, 2022)

We quantify the presence of direct processes in the S-matrix of chaotic microwave cavities with absorption in the one-channel case. To this end the full distribution  $P_S(S)$  of the S-matrix, i.e.  $S = \sqrt{R} e^{i\phi}$ , is studied in cavities with time-reversal symmetry for different antenna coupling strengths  $T_a$  or direct processes. The experimental results are compared with random-matrix calculations and with numerical simulations based on the Heidelberg approach including absorption. The theoretical result is a generalization of the Poisson kernel. The experimental and the numerical distributions are in excellent agreement with random-matrix predictions for all cases.

PACS numbers: 05.45.Mt, 03.65.Nk, 42.25.Bs, 84.40.Dc

Random-matrix theory has been successfully applied to many different scattering systems in several branches of physics ranging from quantum mechanics and mesoscopic physics to sound and microwave systems [1, 2, 3]. The only precondition is the existence of chaotic ray dynamics of the system. Nevertheless, the connection between the statistical properties of scattering and the underlying chaos is not straightforward since scattering may involve two time scales, namely a prompt and a delayed response. Prompt or direct processes are those in which the waves pass through the interaction region without a significant delay. In the equilibrated or delayed processes the waves suffer several reflections inside the interaction region. The delayed processes are usually studied with techniques of random-matrix theory, whereas the direct processes are described in terms of the average of the S-matrix.

Starting from the pioneering work of Lopez, Mello and Seligman [5], there are several theoretical works addressing the statistical distributions of the S-matrix with imperfect coupling or direct processes [6, 7, 8, 9, 10, 11, 12]. This distribution is known in literature as the Poisson kernel. In the one-channel case with no absorption it is possible to parameterize the S-matrix as  $S(E) = e^{i\phi(E)}$ , and the Poisson kernel reads

$$p(\phi) = \frac{1}{2} \frac{1}{\pi} \frac{\text{Im} S i_j^2}{\text{Re} S i_j^2}; \quad (1)$$

where  $\text{Re} S i_j$  is the ensemble (or energy) average of  $S(E)$ . For  $\text{Re} S i_j = 0$  the distribution of the phase  $\phi(E)$  is uniform between 0 and  $2\pi$ , i.e.,  $S(E)$  is uniformly distributed on the unitary circle, in agreement with the circular ensembles of random-matrix theory. Eq. (1) means that the S-matrix distribution of a system including direct processes is fixed by the average  $\text{Re} S i_j$  exclusively.

Following Brouwer [10], the Poisson kernel can be interpreted as follows: For a chaotic system with an attached waveguide with ideal coupling, the distribution of

the S-matrix is uniform. If the coupling in the waveguide becomes non-ideal then the new S-matrix is distributed according to the Poisson kernel. Thus, the Jacobian of the transformation between S-matrices of the system with ideal coupling to the system with non-ideal coupling yields the Poisson kernel, Eq. (1).

Unfortunately the microwave experiments cannot be directly compared with Poisson's kernel Eq. (1) due to losses or absorption. When absorption is present,  $S$  is a subunitary matrix. For the one-channel case the S-matrix can be parameterized as

$$S = \sqrt{R} e^{i\phi}; \quad (2)$$

where  $R$  is the reflection coefficient. The coupling between the scattering channels and the interior region can be quantified by the transmission coefficient  $T_a$  of a barrier describing the direct processes:

$$T_a = 1 - \text{Re} S i_j^2; \quad (3)$$

The subindex  $a$  will be used to denote the antenna coupling. For perfect antenna coupling ( $T_a = 1$ ) there are some exact results. The phase  $\phi$  is uniformly distributed between 0 and  $2\pi$  as before. The distribution  $P_{R,0}(R)$  of  $R$  is known in the cases of strong ( $T_a = 1$ ) [13] and weak ( $T_a \ll 1$ ) absorption [14] for systems with and without time-reversal symmetry ( $\beta = 1; 2$ ). Throughout this letter the subindex "0" refers to perfect coupling. In case of system without time-reversal symmetry and a single perfectly coupled channel the distribution  $P_{R,0}(R)$  was calculated for any absorption strength by Beenakker and Brouwer [14], as well as for two perfectly coupled channels in presence of time-reversal symmetry. For systems with imperfect coupling and absorption the distributions of the proper time delays and reflection eigenvalues are only known for  $\beta = 2$  [15]. More recently, a general distribution of the reflection eigenvalues has been obtained for a large number of propagating channels, independent

FIG. 1: Sketch of the model for scattering with direct processes and absorption. In (a)  $S_0$  describes the scattering of a billiard with absorption but perfect coupling to the lead ( $T_a = 1$ ). In (b) we associate the S-matrix  $S_a$  given by Eq. (5) to the barrier that describes the non-ideal coupling. The resulting S-matrix of the system with absorption and coupling  $T_a$  can be written in terms of  $S_0$  and  $S_a$ .

often time-reversal symmetry [16]. Other quantities, such as probabilities of no return, distributions of Wigner time delay have also been obtained for systems with absorption [17, 18].

From the experimental point of view the effect of the absorption has been studied on the S-matrix correlation function [19, 20], the reflection coefficient [4, 19], the cross-correlation functions of the S-matrix [21], the transmission coefficient [22] and very recently on the impedance matrix [23].

In this paper measurements are presented which provide clear evidence of direct processes in chaotic scattering with absorption. In particular the distribution  $P(\varphi)$  of the phase of the subunitary S-matrix given in Eq. (2) will be obtained. This corresponds to a generalization of Poisson's kernel, Eq. (1), including absorption. Also the full experimental distribution  $P_S(S)$  of the S-matrix in presence of both absorption and direct processes for the one-channel case is given. Both distributions are related through  $P(\varphi) = \int_0^1 P_S(S) dR$ . We compare our measurements with numerical simulations based on the Heidelberg approach and with our random-matrix analytical calculations.

To derive the distribution  $P_S(S)$  of the S-matrix in the presence of direct processes and absorption for the one-channel case we consider the systems of Fig. 1. In Fig. 1(a) a system with absorption strength  $\gamma$  and perfect coupling ( $T_a = 1$ ) is shown. Let us denote by  $S_0 = \frac{1}{R_0} e^{i\varphi}$  the S-matrix describing the scattering in that case. We assume that the distribution  $P_{S;0}(S_0)$  of  $S_0$  is known. Actually it is sufficient to know the distribution of the reflection coefficient  $P_{R;0}(R_0)$  under the assumption that  $R_0$  and  $\varphi$  are still uncorrelated when absorption is present. As we mention above, the phase is uniformly distributed in the case of perfect coupling and no absorption, i.e.,

$$P_{S;0}(S_0) = \frac{1}{2} P_{R;0}(R_0); \quad (4)$$

Just as for systems without absorption, the S-matrix of the system with direct processes and absorption given by Eq. (2) can be written in terms of the S-matrix of the system with absorption but without direct processes,

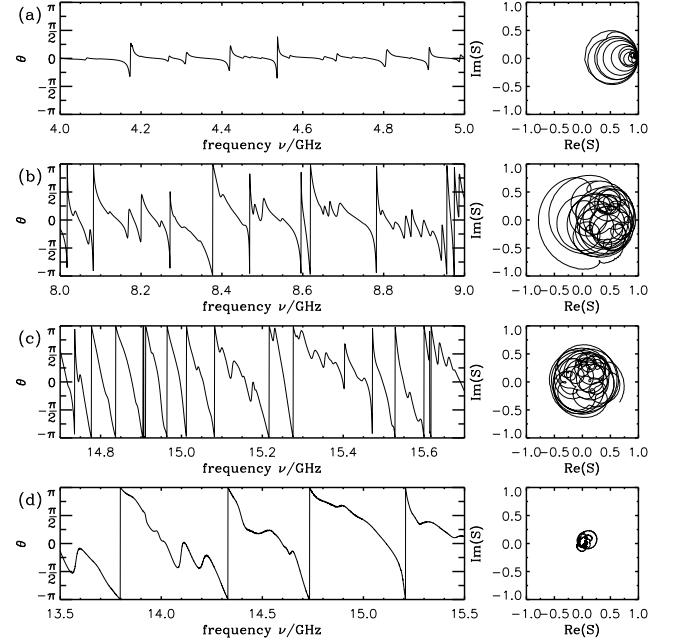

FIG. 2: The phase of the S-matrix for different coupling and absorption regimes: (a)  $\gamma = 0.56$ ,  $T_a = 0.116$  (weak absorption-weak coupling), (b)  $\gamma = 2.42$ ,  $T_a = 0.754$ , (c)  $\gamma = 8.40$ ,  $T_a = 0.989$ , and (d)  $\gamma = 48.00$ ,  $T_a = 0.998$  (strong absorption-nearly perfect coupling). The corresponding Argand diagrams are shown on the right hand side.

$S_0$ , and the S-matrix of the barrier  $S_a$  that describes the non-ideal coupling of the antenna (see Fig. 1(b)). As a model, we take the S-matrix of the barrier to be

$$S_a = \frac{P \frac{1}{T_a}}{P \frac{1}{T_a}} \frac{P \frac{1}{T_a}}{P \frac{1}{T_a}}; \quad (5)$$

where  $T_a$  is the transmission coefficient of the coupling barrier. The combination rule of S-matrices gives the following relation between  $S$  and  $S_0$

$$S_0(S) = \frac{S}{1} \frac{\text{hSi}}{\text{hSi}}; \quad (6)$$

where  $\text{hSi} = P \frac{1}{1 - T_a}$ . Then the distribution  $P_S(S)$  for the system including direct processes is  $P_{S;0}(S_0)$  times the Jacobian of the transformation (6). The result is

$$\begin{aligned} P_S(S) &= \frac{\partial(R_0; \varphi)}{\partial(R; \varphi)} P_{S;0}(S_0) \\ &= \frac{1}{\int_0^1 \frac{\text{hSi}^2}{S \text{hSi}^2}} \frac{1}{2} P_{R;0}(R_0); \end{aligned} \quad (7)$$

where  $R_0 = \int_0^1 \frac{1}{1 - R_0} dR_0$ . The distribution  $P_{R;0}(R_0)$  is known for several cases [13, 14]:

$$\begin{aligned} P_{R;0}(R_0) &= \begin{cases} \frac{8}{\pi} \frac{\exp[-\frac{1}{2}(1-R_0)]}{(1-R_0)^3} [A + B(1-R_0)]; & 0 \leq R_0 < 1; \\ C e^{-\frac{1}{2}(1-R_0)} = (1-R_0)^{2+\frac{1}{2}}; & R_0 = 1; \\ e^{-R_0}; & R_0 > 1; \end{cases} \end{aligned} \quad (8)$$

FIG. 3: Distribution of the S-matrix for the same ranges of coupling and absorption of Fig. 2. The upper, central and lower rows correspond to experiment, numerics and theory, respectively. Note the change of scales for R and  $\theta$ .

where  $\gamma = \gamma_0/2$ ,  $A = (e^{-\gamma} - 1)$ ,  $B = (1 + e^{-\gamma})$ , and  $C = (1 + e^{-\gamma})^2 = (1 + \gamma/2)$ . In the first case of Eq. (8) the absorption can take any value, whereas in the other cases  $\gamma$  can take any value. As our experimental results are for a time reversal system we need the distribution for  $\gamma = 1$ . An approximate distribution for  $\gamma = 1$  was given in Ref. [15], that is valid, however, for intermediate and strong absorption only. The following interpolation formula

$$P_{R,0}(R_0) = C \frac{e^{-\frac{1-R}{R_0}}}{(1-R)^{2+\gamma/2}} \frac{h}{A^{-2} + B(1-R)^{-2}} \quad (9)$$

with  $C = \frac{1}{\Gamma_1} (A(1 + \gamma/2) + B e^{-\gamma})^{-1}$ , where  $(x; \gamma) = \int_0^x t^{\gamma-1} e^{-t} dt$  is the upper incomplete Gamma function. It satisfies all cases of Eq. (8). Notice that the theory presented here is rigorous for the imperfect coupling or direct processes, only the ansatz given by Eq. (9) for the absorption is heuristic.

The experimental setup was described in Ref. [4]. The following two systems were investigated: i) a half Sinai billiard and ii) a half Sinai billiard with a microwave absorber attached to one side. To improve statistics, in both cases the semicircle was moved along the wall in steps of 5 mm to obtain more than 50 measurements. The complex S-matrix was measured with a vector network analyzer. We investigated four different regimes also considered in Ref. [4] ranging from weak absorption and weak coupling ( $\gamma = 0.56$ ,  $T_a = 0.116$ ) to strong absorption and nearly perfect coupling ( $\gamma = 48$ ,  $T_a = 0.998$ ). The one-channel case is realized due to the fact that only a single antenna is attached with a radius much smaller than the

wavelength.

In Fig. 2 we plot the phase of S as a function of the frequency and the corresponding Argand diagrams of the scattering matrix S for different coupling and absorption regimes. The experimental value of  $T_a$  is obtained directly from the mean value of the S-matrix by Eq. (3). The measured value of  $hR$  then fixes the absorption strength which decreases monotonically as a function of  $hR$  and viceversa.

To test the theoretical and experimental results we made numerical simulations based on random matrix theory using the Heidelberg approach. To obtain the numerical distributions we used an ensemble of S-matrices constructed according to

$$S(E) = 1 - 2iW^\dagger(E - H + iWW^\dagger)^{-1}W; \quad (10)$$

where H is taken from the Gaussian orthogonal ensemble and W gives the coupling between the resonant modes of the cavity and the channel states, and E is related to the electromagnetic frequency by Weyl's formula. More details of the numerical method can be found in Ref. [4].

In Fig. 3 we plot the experimental distributions of the S-matrix for the same cases as in Fig. 2. The numerical distributions are also included in order to test the theoretical ones based on Eqs. (4), (7), and (9). An excellent agreement between theory, numerics and experiment is found. Finally, in Fig. 4 we show the distribution  $P(\gamma)$  for the different regimes of absorption and antenna coupling. The numerical simulation is included as well as the theoretical results obtained by integrating Eq. (7) numerically.

FIG. 4: Experimental distribution  $P_{\theta,T}(\theta)$  (histogram) for the same regimes of coupling and absorption as given in Fig. 2. Additionally the numerical (crosses) and the theoretical (solid line) is plotted as well. In (d) the dotted curves correspond to the coupling strengths  $T_a = 0.996$  and  $1$ , respectively.

ically. A gain an excellent agreement is found for Fig. 4 (a)–(c). The deviations in the case of strong absorption and nearly perfect coupling,  $T_a = 0.998$ , (Fig. 4 (d)) are due to the fact that the distribution  $P(\theta)$  depends very sensitive on the coupling parameter  $T_a$ . Within the investigated frequency range the coupling  $T_a$  changes, which is not taken into account in the theory. We additionally plotted the theoretical distributions for  $T_a = 0.996$  and  $1$ .

In conclusion, we have shown experimental evidence of direct processes in the scattering of chaotic microwave cavities in presence of absorption. This was done by i) obtaining the experimental distribution of the S-matrix for various regimes of absorption and antenna coupling in the one-channel case, ii) obtaining the same distributions numerically using the Heidelberg approach, and iii) presenting a theory that generalizes Poisson's kernel to include absorption. Excellent agreement between theory, numerics and experiment was obtained in all regimes of absorption and antenna coupling.  $P_{R,0}(R_0)$  as given by Eq. 9 is not rigorously derived for  $\gamma = 1$ . As soon as a rigorously derived result becomes available it can be

plugged into Eq. (7) to get the exact distribution of the S matrix for any absorption and antenna coupling.
