#### Abstract

We compare magnetoresistances (MR) and switching currents ( $\mathrm{I}_{\mathrm{s}}$ ) at room temperature ( 295 K ) and 4.2 K for Permalloy/N/Permalloy nanopillars undergoing current-induced magnetization switching (CIMS), with nonmagnetic metals $\mathrm{N}=\mathrm{Cu}, \mathrm{Ag}$, and Au . The N -metal thickness is held fixed at 10 nm . Any systematic differences in MR and $\mathrm{I}_{\mathrm{s}}$ for the different N -metals are modest, suggesting that Ag and Au represent potentially viable alternatives for CIMS studies and devices to the more widely used Cu.

Most experimental studies of current-induced magnetization switching (CIMS) in ferromagnetic/nonmagnetic/ferromagnetic (F/N/F) trilayer metal nanopillars have used $\mathrm{N}=\mathrm{Cu}$ as the spacer layer [see, e.g., 1-8]. None has yet used $\mathrm{N}=\mathrm{Ag}$ or Au . Ag has the potential advantage for devices of sometimes giving a larger Current-Perpendicular-to-Plane (CPP) magnetoresistance (MR) with Permalloy (Py = $\mathrm{Ni}(84) \mathrm{Fe}(16)$ ) [9]. Au has the advantage of being insensitive to atmospheric contamination. We, thus, decided to compare MR and CIMS data at 295 K and 4.2 K for Py-based nanopillars with $\mathrm{N}=\mathrm{Cu}, \mathrm{Ag}$, and Au .

Our sputtered samples have approximately elliptical shape with dimensions $\sim 70 \mathrm{~nm} \times 130 \mathrm{~nm}$. dV/dI was measured with a lock-in amplifier at frequency $\sim 8 \mathrm{kHz}$ and measuring current $\sim 20 \mu \mathrm{~A}$. Details of sample preparation and measurements are given in [6,10]. Fig. 1 compares representative MR and CIMS switching data at 295 K for samples of $\operatorname{Py}(24 \mathrm{~nm}) / \mathrm{N}(10 \mathrm{~nm}) / \operatorname{Py}(6$ nm ) nanopillars with $\mathrm{N}=\mathrm{Cu}, \mathrm{Ag}$, and Au. Fig. 2 compares the same quantities for the same samples at 4.2 K . Table I compares average values of the total resistance, $R$, the change in resistance upon switching, $\Delta \mathrm{R}$, the magnetoresistance, $\operatorname{MR}(\%)=(\Delta R / R) \times 100 \%$, the difference $\Delta \mathrm{I}_{\mathrm{s}}=\mathrm{I}_{\mathrm{s}}^{+}-\mathrm{I}_{\mathrm{s}}^{-}$between positive $(+)$and

Fig. 1. MR(top) and CIMS(bottom) at 295 K for $\mathrm{Py} / \mathrm{N} / \mathrm{Py}$ nanopillars with $\mathrm{N}=\mathrm{Cu}$ (left), Ag (middle) and Au (right). Layer thicknesses are in nm .

Fig. 2. MR (top) and CIMS (bottom) at 4.2 K for $\mathrm{Py} / \mathrm{N} / \mathrm{Py}$ nanopillars with $\mathrm{N}=\mathrm{Cu}$ (left), Ag (middle), and Au (right). Layer thicknesses are in nm .
negative (-) switching currents, $\mathrm{I}_{\mathrm{s}}$, and the upper magnetic switching field, $\mathrm{H}_{\mathrm{s}}$, over 3 to 5 samples of each type at 295 K (top three data sets) and 4.2 K (bottom three data sets). The average resistances of the three sets of samples differ, due to an unknown mix of variation in areas (smaller area increases R, does not change MR, and decreases $\Delta \mathrm{I}_{\mathrm{s}}$ ) and contact resistances (larger contact resistance increases R, decreases MR, and may leave $I_{s}$ unchanged). Thus, a precise comparison between them cannot be made. However, at both temperatures, the MRs and $\Delta I_{s}$ are roughly similar for all three metals. We conclude that Ag and Au represent potentially viable alternatives to Cu for studies of CIMS physics and for CIMS-based devices.

Table I. Average values of $\mathrm{R}, \Delta \mathrm{R}, \mathrm{MR}(\%), \Delta \mathrm{I}_{\mathrm{s}}$, and $\mathrm{H}_{\mathrm{s}}$ at 295 K (top three rows) and 4.2 K (bottom three rows) of $\mathrm{Py} / \mathrm{N} / \mathrm{Py}$ with $\mathrm{N}=\mathrm{Ag}, \mathrm{Au}, \mathrm{Cu}$. The 295K data are
averaged for each metal over 3-5 samples; those at 4.2 K are averaged over 3 samples.
