W e exam ine the interplay of the K ondo e ect and the R K K Y interactions in electronic G ri ths phases using extended dynam icalm ean- eld theory m ethods. W e nd that sub-O hm ic dissipation is generated for su ciently strong disorder, leading to the suppression of K ondo screening on a nite fraction of spins, and giving rise to universal spin-liquid behavior.

PACS num bers: 71.27.+ a, 75.20 H r, 75.10 N r

D isorder induced non-Ferm i liquid (NFL) behavior has remained an important focus of study in heavy ferm ion system s [1]. A coording to the \m agnetic G ri ths phase" scenario [2], this behavior rejects the form ation of rare m agnetic clusters with large susceptibilities, sim ilarly as in disordered insulating magnets [3]. A nother approach focused on the interplay of disorder and the K ondo effect far away from any magnetic ordering [4]. More recent work [5, 6] has dem onstrated that such \electronic G ri ths phases" are a generic feature of strongly correlated electronic system s with disorder. Neither picture, how ever, seem s satisfactory for the following key reason: in both scenarios, the resulting NFL behavior is characterized by power law anom alies, with non-universal, rapidly varying powers. In contrast, most experimental data seem to show reasonably weak anom alies, close to m arginal Ferm i liquid behavior [1].

Physically, it is clear what is missing from the theory. Sim ilarly asm agnetic G ri thsphases, the electronic Gri ths phase is characterized [4, 5, 6] by a broad distri- $(T_{K})^{1}$  of local energy scales (K ondo bution P  $(T_{K})$ tem peratures), with the exponent W<sup>2</sup> rapidly decreasing with disorder W . At any given temperature, the local moments with  $T_K$  (i) < T remain unscreened. As disorder increases, the number of such unscreened spins rapidly proliferates. W ithin the existing theory [4, 5, 6] these unscreened spins act essentially as free local m om ents and provide a very large contribution to the therm odynam ic response. In a more realistic description, how ever, even the K ondo-unscreened spins are not com pletely free, since the m etallic host generates longranged Ruderm an-Kittel-Kasuya-Yosida (RKKY) interactions even between relatively distant spins. As the RKKY interaction has an oscillatory character, the effective interactions between the (random ly located) unscreened spins will be random in m agnitude and sign. In this Letter, we use an extended dynam icalm ean eld formulation to exam ine the role of such RKKY interactions within the electronic G ri ths phase scenario.

O ur main results are as follows: (a) for disorder W weaker than a critical value W  $_{\rm c}$  we nd Ferm i liquid behavior, but for W > W  $_{\rm c}$  the K ondo e ect is suppressed

on a nite fraction of spins, resulting in a spin-liquid phase displaying (universal) marginal Ferm i liquid behavior; (b) the spins that remain screened are still characterized by a power law distribution of (renormalized) energy scales P (T) (T)<sup>1</sup>, but the exponent acquires a universal value 1=2 throughout the spinliquid phase; (c) the spin liquid phase is unstable to spin glass ordering at the lowest tem peratures, but we nd robust marginal Ferm i liquid behavior in a broad tem – perature window above the freezing tem perature.

W e consider the disordered K ondo lattice m odel as given by the H am iltonian

$$H = t X X X V_{i}c_{i}^{y}c_{j} + H.c. + V_{i}c_{i}^{y}c_{i}$$

$$H = t V_{i}c_{i}^{y}c_{i} + J_{K}c_{i} + J_{K}c_{i} + J_{i}c_{i}^{y}c_{i}$$

$$H = t V_{i}c_{i}^{y}c_{i} + J_{i}c_{i}^{y}c_{i} + J_{i}c_{i}^{y}c_{i} + J_{i}c_{i}^{y}c_{i}$$

$$H = t V_{i}c_{i}^{y}c_{i} + J_{i}c_{i}^{y}c_{i} + J_{i}$$

where the exchange couplings  $J_{ij}$  between localized spins, and site energies  $v_i$  are distributed according to G aussian distributions,  $P_J(J_{ij}) \exp(J_{ij}^2=2J^2)$  and  $P_W(v_i) \exp(v_i^2=2W^2)$  [6]. In this expression,  $S_i$  and  $s_i = \frac{1}{2} c_i^y c_i$  represent a localized spin and the conduction electron spin density at site i, respectively. We concentrate on the param agnetic phase. Applying the standard procedure to average over disorder in the  $J_{ij}$  couplings [7] and taking the lim it of in nite coordination z ! 1 [8], the local electron assumes the form

$$A_{j} = \begin{array}{cccc} X & Z & Z \\ & d & d & ^{0}C_{j}^{y}() \left[ (0 + v_{j}) & ( & ^{0}) \right] \\ & & & Z \\ t^{2}G_{c}( & & ^{0}) C_{j}( & ^{0}) + J_{K} & d & S_{j}( & ) & _{j}S( & ) \\ & & & & \\ \frac{J^{2}}{2} & Z & & & 0 \\ \hline \frac{J^{2}}{2} & & & & 0 \\ & & & & & 0 \end{array}$$

The local action of Eq. (2) describes the so-called Bose-Ferm i K ondo model [9, 10], which describes a K ondo spin interacting with both a ferm ionic bath of conduction electrons and a bosonic bath of spin uctuations. For a disordered K ondo lattice, we must consider an ensemble of such in purity models supplemented by following selfconsistency conditions.  $_{R}^{T}$  he bosonic spin bath () = hT S<sub>j</sub>()  $_{s}(0)i_{A_{j}} = dv_{j}P_{W}(v_{j})hT S_{j}() \underbrace{}_{s}(0)i_{A_{j}}$ and the conduction electron bath G<sub>c</sub>() = G<sub>cj</sub>() =

hT  $c_j$  ()  $\dot{d}_j$  (0)  $i_{A,j}$  are obtained by appropriate disorder averaging [6], and for simplicity we use a simple sem icircular model density of states for conduction electrons.

Destruction of the Kondo e ect. The presence of RKKY interactions introduces a qualitative modi cation in the dynam ics of the Kondo spins, through the presence of a dissipative bosonic bath of spin uctuations. This behavior depends crucially on the precise spectral form of the bosonic bath, allowing for the destruction of the Kondo e ect in the presence of sub-Ohm ic dissipation [9, 10]. For a spectrum of the form

Ferm i liquid behavior is recovered for " = 0, but for " > 0 (sub-0 hm ic dissipation), and for su ciently sm all bare K ondo temperature  $T_K$ , the spin decouples from the conduction electrons. W ithin an electronic G rifths phase, however, the disordered K ondo lattice has a very broad distribution of local K ondo temperatures P ( $T_K$ ) ( $T_K$ )<sup>1</sup>. Therefore, for " > 0 and arbitrarily weak coupling to the bosonic bath (i.e. weak RKKY interaction), a fraction of the spins will decouple.

To obtain a su cient condition for decoupling, we exam ine the stability of the Ferm i liquid solution, by considering the lim it of in nitesim alRKKY interactions. To leading order we replace () !  $_{\circ}()$ (;J = 0),and the calculation reduces to the \bare model" of Ref. [6]. The resulting bosonic bath, which is an average over the site-dependent local dynam ic spin susceptibility,  $_{o}$  (i!  $_{n}$ ) =  $dT_{K} P$  ( $T_{K}$ ) ( $T_{K}$ ; i!  $_{n}$ ), has a Ferm i liquid form in the presence of weak disprder. However, for stronger random ness, W > W $t^2$  <sub>c</sub>J<sub>K</sub> =2 cor-< 2 (here,  $_{\rm c}$  is the density of states responding to for conduction electrons) [6], the power law distribution of energy scales within a Gri ths phase produces sub-0 hm ic dissipation, corresponding to " = 2> 0. Note that the estim ate based on the bare theory sets an upper bound for the true critical disorder strength, i.e.  $W_c < W = W_{nfl} = \frac{1}{2}$  (here,  $W_{nfl} = \frac{1}{2} \frac{1}{c} J_K = 2$  is the threshold for NFL behavior in the bare model [6], corresponding to = 1). We emphasize that within the electronic G ri ths phase, such decoupling em erges for  $W > W_{c}$  even for arbitrarily small J, in contrast to the clean case [11] where much stronger RKKY interactions  $(J > J_c = 10 T_K)$  [12] are required to destroy the K ondo e ect.

The spin liquid phase. For nite J, the actual value of " has to be self-consistently determ ined, as follows. For  $W > W_c$ , the spins break up into two groups: the decoupled spins and those that remain K ondo screened. Since the self-consistent bosonic bath function (i!<sub>n</sub>) is an algebraic average over all spins, it is an additive function of the contributions from each uid

$$(i!_n) = n_{dc} (i!_n) + (1 n)_{s} (i!_n):$$
 (3)

Here, n is the fraction of spins in the decoupled phase. As we shall see, the functions  $_{dc}$  (i!<sub>n</sub>) and  $_{s}$  (i!<sub>n</sub>) both have a singular, non-Fermi liquid form characterized by exponents "<sub>dc</sub> and "<sub>s</sub>, respectively. Deferring for a moment the study of the critical region (in nitesim ally small n), we rst exam ine the solution deep within the spin liquid phase. The rst step in the self-consistent procedure is computing "<sub>dc</sub> and "<sub>s</sub> for a given value of the bath exponent ". The spin autocorrelation function in the decoupled phase assumes the form [9, 10]  $_{dc}$  () = hT S () S (0)i 1=", a result valid to all orders in "[10]. Since "<sub>dc</sub> is de ned by  $_{dc}$  ()  $1=^{2}$ " dc, we nd

$$"_{dc}(") = 2$$
 ": (4)

The non-analytic part of  $_{\rm s}$  (i!  $_{\rm n}$ ) comes from the spins with the smallest (renorm alized) K ondo tem peratures T (\barely screened spins")

$$Z_{bs}(i!_{n}) = dT P(T)_{bs}(T;i!_{n}): (5)$$

Here P (T ) is the distribution of renormalized Kondo tem peratures (local Ferm i liquid coherence scales), and bs (T ; i! n) is the local dynam ic susceptibility for a given T . Properties of the Bose-Ferm i Kondo model in the critical region of the decoupling transition have been extensively studied within renormalization group (RG) [9, 10] and large-N approaches [11], and we use these results to calculate bs. In particular, T  $(T)^{1}$ (  $T_K$  ) , which gives dT =dT<sub>K</sub> (J<sub>k</sub>) Therefore P (T ) = P  $[T_K (T)]dT_K = dT$  $dT_K = dT$  $(T)^{1=1}$ . From scaling arguments [9, 10], bs (T;!) = $(T)^{1}$  (!=T), where is the anomalous dimension, which is known to be exactly " [10]. Perform ing the integration in Eq. (5), we nd at low frequencies  $b_{s}$  (i! n) = bs (0) C "  $j!_n j^{+1}$ , or, equivalently, at large times  $1 = \frac{1}{2}$ . By de nition, s()  $1 = \frac{2}{3}$ , which <sub>bs</sub> ( ) gives

$$"_{s}(") = 2$$
  $1 = :$  (6)

Since = " and > 0 (as the relevant eigenvalue at the unstable xed point), Eqs. (4) and (6) in ply that " $_{dc}$  > " $_{s}$ . Therefore, " = m axf" $_{dc}$ ;" $_{s}g$  = " $_{dc}$ , and from Eq. (4) we nd that the self-consistent bath is characterized by the exponent " = 1; as in the spin liquid m odel of Sachdev and Ye [13], producing a logarithm ic divergence of the average local dynam ic susceptibility. Note that, in contrast to the bare (J = 0) m odel of the electronic G rifths phase, the renorm alized distribution P (T ) of local energy scales now assumes a universal form characterized by an exponent (") = 1= (") "=2 = 1=2 within the spin liquid phase. More work is needed to determ ine the behavior of the uniform susceptibility, as well as the behavior of the speci cheat.

Transport in the spin liquid phase. A lthough the renorm alized K ondo coupling scales to zero for the decoupled spins, the precise form of the RG ows (scaling dimension of \irrelevant operators") near the spin-liquid xed point still determ ines the nite frequency (or nite tem perature) corrections. To leading order, the contribution from decoupled spins scales as (!)  $[J_{\kappa}(!)]^2$ , while  $J_{\kappa}$  (!) !<sup>1=</sup> . To compute the appropriate exponent at the spin-liquid xed point we have used the "-expansion approach of Ref.[10], and we nd  $= 2 = " + 0 ("^3).$ From our self-consistent solution for the spin-liquid phase (" = 1), we obtain 1= 1=2, producing again a m arginal Ferm i liquid correction to the resistivity  $d_{c}(!)$  !, or at ! = 0 and nite tem perature

dc(T) T:

Numerical results. As an illustration of our analytical predictions, and to obtain quantitative results, we proceed to the numerical solution of our equations in the large-N limit [11, 13]. Introducing site-dependent slave boson parameters  $r_j$  and " $_{fj}$ , and m inimizing the local free energy, we come to the following saddle-point equations [11]

$$\frac{1}{2} \sum_{i=1}^{X} e^{i!_{n}0^{+}} G_{fj}(i!_{n}) = \frac{1}{2};$$
 (7)

$$\frac{1}{J_{K}} G_{fj}(i!_{n}) f_{j}(i!_{n}) = \frac{1}{J_{K}} :$$
 (8)

The local f-pseudo-ferm ion G reen's function  $G_{fj}() = hT f_j()f_j^y(0)i$ , is given by  $G_{fj}^1(i!_n) = i!_n$ "fj j(i!\_n)  $r_j^2$  fj(i!\_n). The self-energy is equal to j() = J<sup>2</sup> ()Gfj(), and  $\frac{1}{fj}(i!_n) = i!_n + \frac{v_j t^2G_c(i!_n)}{G_{fj}()G_{fj}()}$ , self-consistency requires () =  $\frac{G_{fj}()G_{fj}()}{G_{fj}()G_{fj}()}$ , and  $G_c(i!_n) = \frac{G_{cj}(i!_n)}{G_{cj}(i!_n)}$ , where  $G_{cj}^{1}(i!_n) = \frac{1}{fj}(i!_n) r_j^2 = [i!_n "f_j j(i!_n)]$ :

These equations were solved on the in aginary axis at T = 0 using fast Fourier transform methods. The total average local dynamic susceptibility together with the contributions coming from K ondo screened s and decoupled spins dc is shown in Fig.1(a). At low frequencies, the contribution from K ondo screened spins saturates to a constant, while the decoupled spins produce a logarithmic divergence. A comparison with the bare model illustrates how the strong power law divergence of found for J = 0 is suppressed by the dynam icalRKKY interactions. Fig.1(b) shows how evolves with the change of disorder. Note that marginal Fem i liquid behavior persists up to a crossover scale  $!_{s1} = 0$ :  $T_K (v_j = 0)$  which has very weak dependence on the disorder strength.

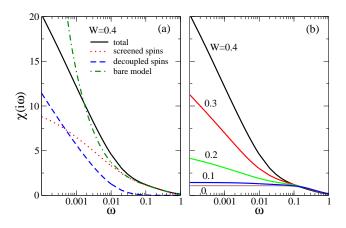

Figure 1: Local dynam ic m agnetic susceptibility. (a) At low frequencies, the decoupled spins (dashed line) provide the leading logarithm ic dependence of the total averaged susceptibility (full line). For the values of the param eters used  $(J_{\rm K}~=~0.8, J~=~0.05,~=~0.1$  in units of the halfbandwidth, corresponding to  $T_{\rm K}~(v_{\rm j}=0)=0.1$  and W  $_{\rm C}~0.1$ ), there are n = 8% of decoupled spins at W = 0.4. The bare model (J = 0) leads to a stronger non-universal power law singularity (dash-dotted line). (b) (i!) for the disorder strength ranging from 0 to 0.4.

Critical behavior. Near the critical point the arguments which followed Eq. (3) have to be modied since the relative importance of the various contributions to the average local susceptibility changes. First, we concentrate on the contribution from the barely screened spins given by Eq. (5). As before, P(T) =P  $[T_K (T)]dT_K = dT$ , but close to the transition P  $(T_K)$ is small and cannot be replaced by a constant prefactor of order 1. Since P ( $T_K$ ) P ( $T_{Kc}$ ) ( $T_{Kc}$ ) <sup>1</sup>, we nd  $_{\circ}^{T_{K\,c}}$  dT\_K P (T\_K) (T\_K\_c) , where T\_K\_c is the bare n = 0K ondo tem perature at the site energy  $v_c$  at which the spins start to decouple. Therefore P  $(T_{\kappa})$ n<sup>(1)=</sup>. From the bare model, we know that (for small J) 2 near the critical point. Now we are in a position to write down the general form of the total bosonic bath at low frequencies

$$(i!_n) = {}_{o} C_1 j!_n j C_2 n^{1=2} j!_n j^{+ -1} C_3 n \ln j!_n j;$$
  
(9)

The rst two terms come from the well screened spins and have the Ferm i liquid form. The third term is due to the \barely screened" spins and the last term is the contribution from the decoupled spins. The crucial point is that the non-analytic term from the barely screened spins, being proportional to  $\frac{P}{n}$ , is much larger than the logarithm ic term due to the n decoupled spins, except at exponentially small frequencies. Therefore, we can neglect the last term in Eq. (9). Below the crossover frequency !  $n^{(1=2)=[2]} (1=)]$ , the non-analytic term in Eq. (9) is dom inant and close to the decoupling point,

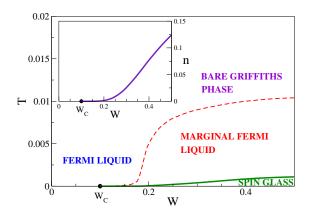

Figure 2: Phase diagram obtained for the same values of param eters as in Fig. 1. The inset shows the fraction of decoupled spins as a function of disorder. Note that the decoupling sets in already in the presence of moderate disorder.

i.e. in the lim it "<sub>fj</sub> ! 0 and  $r_j^2$  ! 0, G<sub>f</sub> assumes the form G<sub>f</sub>(i!) iC sgn != j!  $\frac{1}{2}$  "<sup>=2</sup> for j! j< !, and G<sub>f</sub>(i!)

i=! for j! j > ! . The parameter " has to be selfconsistently determ ined from the equation 1 " = + <sup>1</sup> 1.W ithin the large-N theory, = 2="which gives " = 4=5. Inserting this expression into Eq. (8), we nd the critical site energy for decoupling  $v_c$  jlnnj. Since the number of decoupled spins is equal to n =  $v_c$  dvP<sub>W</sub> (v), we have a closed set of equations forn (W), from which we nd that the number of decoupled spins is exponentially

small in the vicinity of the critical point

$$n e^{A = (W W_{c})}; \qquad (10)$$

where A is a positive constant. The num erical results for n(W) are shown in the inset of Fig. 2. Interestingly, no precursors (vanishing coherence scale of the Fermiliquid) arise as the critical point is approached from the FL side, in contrast to what we have found by solving the same equations in absence of disorder [11]. This indicates a novel type of quantum critical behavior that has a character of an essential singularity, a feature that appears speci c to quantum G ri ths phases.

Spin glass instability and phase diagram. In this paper we have concentrated on the param agnetic solution of our m odel. However, the decoupled spins can be expected to form a spin glass (SG) at low temperatures in the presence of random inter-site interactions [7]. For a rigorous treatment of the spin glass phase, one needs to go beyond the N = 1 limit, but a rough estimate of the temperature for SG ordering [11] may be obtained by using the large-N approach as an approximate theory for the considered N = 2 case. The spin glass instability criterion [7], as appropriately generalized to the case of additional site random ness then reads

$$q = \frac{1}{\sum_{j=1}^{2} j} p_{\overline{2}} = 1:$$
 (11)

Fig. 2 represents a generic phase diagram of our model. For weak disorder the system is in the Ferm i liquid phase, while for  $W > W_c$  the marginal Ferm i liquid phase emerges. The crossover temperature (dashed line) delimiting this regime can be estimated from the frequency up to which the logarithm is behavior in (i!) is observed [14]. The spin glass phase, obtained from Eq. (11), appears only at the lowest temperatures, well below the marginal Ferm i liquid boundary [14]. Interestingly, recent experiments have indeed found evidence of dynam ical spin freezing in the millik elvin temperature range for som e K ondo alloys [15].

To sum marize, we have introduced and solved a disordered K ondo lattice model with random inter-site RKKY interactions. Our solution, valid with in extended dynam – ical mean-eld theory, illustrates how non-O hm ic dissipation arising from inter-site RKKY interaction restores universality for non-Ferm i liquid behavior of electronic G ri ths phases. A lthough considerably di erent in detail, this dissipative mechanism is reminiscent of the processes leading to dynam ical freezing of droplets within m agnetic G ri ths phases [16], suggesting a generic role of RKKY interactions in disordered heavy ferm ion system s.
