#### Abstract

I present a generalization of the Ehrenfest um model that is aim ed at sim ulating the approach to equilibrium in a dihute gas. T he present $m$ odeldi ens from the original one in tw o respects: 1) the two boxes have di erent volum es and are divided into identical cells w ith either multiple or single occupancy; 2) particles, which carry also a velocity vector, are sub jected to random, but elastic, collisions, both mutual and against the container walls. I show, both analytically and num erically, that the num ber and energy of particles in a given um evolve eventually to an equilibrium probability density $W$ which, depending on cell occupancy, is binom ial or hypergeom etric in the particle num ber and beta-like in the energy. M oreover, the B oltzm ann entropy $\ln W$ takes precisely the same form as the therm odynam ic entropy of an ideal gas. This exercise can be useful for pedagogical purposes in that it provides, although in an extrem ely sim pli ed case, a probabilistic justi cation for the $m$ axim um -entropy principle.

PACS num bers: 02.50 G a, $02.50 \mathrm{Ng}, 0520 \mathrm{D} \mathrm{d}$
KEY W ORDS: U m m odels; Boltzm ann entropy; m axim um -entropy principle.

## 1 Introduction

The m odem intuition of the em ergence of the Second Law of therm odynam ics from $m$ echanics is $m$ ainly grounded upon the behaviour of stochastic um m odels, where \particles" are sub jected to a probabilistic dynam ics that eventually generates a sort of them odynam ic equilibrium 畒]. O bviously, th is stochastic (M arkovian) dynam ics is only a caricature of the \real" $\mathbb{N}$ ew tonian) dynam ics; it is much like an e ective dynam ics which em erges after averaging over $m$ any instances of the com plicated short-tim em otion.

In the classical Ehrenfest m odel, N num bered balls are distributed into two ums; at each step of the process, a ball is extracted at random and m oved from the um where it resides to the other. Eventually, the num ber ofballs in each um uctuates around $N=2$, $w$ ith relative deviations from the $m$ ean becom ing negligible in the large-N lim it. This stochastic process is taken to represent the attainm ent of particle-num ber equilibrium in a dihute gas di using between two com $m$ unicating vessels of equal volum e.

In order to im prove the E hrenfest $m$ odelso as to $m$ ake it $m$ ore realistic, I consider a generalization where the balls/particles are endowed w th both a discrete position and a continuous velocity. To be m ore speci c, we are given two boxes, 1 and 2, and $N$ particles in the boxes. B ox 1 (2) is divided into $V_{1}$ $\left(\mathrm{V}_{2}\right)$ identicalcells, w ith $\mathrm{V}=\mathrm{V}_{1}+\mathrm{V}_{2}$ the totalœllnum ber. The occupancy c of the th œll can be eithermultiple ( $c=0 ; 1 ; 2 ;::$ :) or single ( $c=0 ; 1$ ), w ith both possibilities being considered. T he velocity of the a-th particle is $v_{a}$, a three-dim ensional vector $w$ ith com ponents $v_{a k}(k=1 ; 2 ; 3)$.

To $m$ ake things simple, positions and velocities are updated independently and by tums, in such a way that the two dynam ics of free $m$ otion and collisions will proceed in parallel though staying separate. H ence, the stationary state of each set of variables can be analysed on its own. A long this route, one arrives at a probabilistic foundation of the expression of the ideal-gas entropy in them odynam ics and, concurrently, at a justi cation (in this case only) of the $m$ axim um entropy principle.

## 2 P osition updates

Let us rst suppose that each cell can host whatever num ber of particles. A position update consists of i) choosing at random one particle, $a_{r}$, and
one cell, ${ }_{r}$; and ii) $m$ oving $a_{r}$ from its original cell into ${ }_{r}$. In term $s$ of the variable $n$, which counts how $m$ any particles are hosted in box 1 , this de nes a stochastic process of the $M$ arkov type, w ith transition probabilities:

$$
T\left(\begin{array}{ll}
\mathrm{n}+1 & \mathrm{n}
\end{array}\right)=\frac{(\mathbb{N} \mathrm{n}) \mathrm{V}_{1}}{\mathrm{NV} \mathrm{~V}} ; \quad \mathrm{T}\left(\begin{array}{lll}
\mathrm{n} & 1 & \mathrm{n} \tag{1}
\end{array}\right)=\frac{\mathrm{nV} V_{2}}{\mathrm{NV} \mathrm{~V}}:
$$

$T$ he ensuing $m$ aster equation adm its the binom ialdistribution

$$
\begin{equation*}
W(n)=N_{n}^{n}{\frac{V_{1}}{V}}^{n}{\frac{V_{2}}{V}}^{N} \tag{2}
\end{equation*}
$$

as unique stationary distribution Rell $_{1}^{-1}$. Since the $M$ arkov chain is ergodic (i.e., there is a path connecting every ( $m$ acro) state $n$ to every other $n^{0}$ ), any initial distribution $P(n ; 0)$ w ill converge, in the long run, to $W(n)$. In particular, the average n goes eventually into $\mathrm{N} \mathrm{V}_{1}=\mathrm{V}$, w ith relative deviations from the $m$ ean of $\left(\mathbb{N}^{1=2}\right.$ ) 刣]. The $m$ ultiplicity of $m$ acrostate $n$, i.e., the num ber of complexions ( $m$ icrostates) of $N$ num bered particles in the boxes, such that box 1 contains $n$ particles, is just $W$ ( $n$ ) $V^{\mathbb{N}}$. A ssum ing $n ; N \quad n=O(N)$ 1, the equilibrium entropy $S(n)$, de ned as the logarithm of the multiplicity, is additive over the boxes and extensive w ith N :

$$
\begin{equation*}
S(n) \quad n \frac{n}{l_{1}} \quad(N \quad n) \frac{N}{V_{1}} \frac{n}{V_{2}} ; \tag{3}
\end{equation*}
$$

being $m$ axim um for $n=N V_{1}=V$. In Eq ( (Зָㄱ), we recognize the volum e contribution to the ideal-gas entropy.

W hile all of the above is rather standard, a novel result is obtained when each cell in the boxes can contain at m ost one particle. N ow, at each step in the process, the selected particle $a_{r}$ is $m$ oved into a cell $r$ that is chosen at random am ong the vacant sites. The transition probabilities read (w ith $\left.\mathrm{V}_{1} ; \mathrm{V}_{2} \mathrm{~N}\right)$ :

$$
\begin{equation*}
\mathrm{W}(\mathrm{n})=: \tag{5}
\end{equation*}
$$

A $s$ in the previous case, the average $n$ converges eventually to $N V_{1}=V$, w ith relative deviations of $\left(\mathbb{N}^{1=2}\right.$ ). Them ultiplicity of state $n$, i.e., the num ber of ways $N$ indistinguishable particles can be arranged in the boxes, in such a way that $n$ particles are placed in box 1 , is equal to $W(n) \quad{ }_{N}^{V}$. A ssum ing $n ; N \quad n ; V_{1} \quad n ; V_{2}(\mathbb{N} \quad n)=O(\mathbb{N}) \quad 1$, the equilibrium entropy becom es:
$S(n) \quad n \ln _{V_{1}}^{n} \quad\left(V_{1} \quad n\right) \ln 1 \quad \frac{n}{V_{1}}$

being $m$ axim um for $n=N V_{1}=V$. Equation ( $\overline{-}$ ) is nothing but the therm odynam ic entropy of two ideal lattice gases that can $m$ utually exchange energy and particles.

## 3 Velocity updates

The collision dynam ics of equalm ass particles can be roughly schem atized as a succession of random binary events which, how ever, are still required to obey energy and $m$ om entum conservation [-1]. On the $m$ acroscopic side, such collision rules go along w ith the conservation oftotalkinetic energy and total m om entum, thus being appropriate only to a very dihute (gaseous) system of particles. If, $m$ oreover, we are $w$ illing to drop the $m$ om entum constraint, provision should be $m$ ade also for elastic collisions against the walls of the (cubic) container.

A s far as the $m$ utual collisions are concemed, I assum e their outcom e to be as $m$ axim ally random as possible. This am ounts to update the velocities of the colliding particles as:

$$
\begin{equation*}
\mathrm{v}_{\mathrm{a}}!\mathrm{v}_{\mathrm{a}}^{0}=\mathrm{v}_{\mathrm{a}}+\hat{\mathrm{r}} ; \quad \mathrm{v}_{\mathrm{b}}!\mathrm{v}_{\mathrm{b}}^{0}=\mathrm{v}_{\mathrm{b}} \quad \hat{\mathrm{r}} ; \tag{7}
\end{equation*}
$$

$w h e r e=\left(v_{b} \quad v_{b}\right) \quad \hat{r}$, and $\hat{r}$ is picked up at random out of the em isphere of unit-length vectors form ing an acute angle $w$ ith $v_{b} \quad V_{a}$. If $m$ utual collisions occur at a rate of $p$, the $m$ aster equation for the velocities nally reads:

$$
\begin{equation*}
\left(f v^{0} g ; t+1\right)=d^{3 N} v \quad\left(f^{0} v^{g} \quad f v g\right)(f v g ; t) ; \tag{8}
\end{equation*}
$$

$$
\begin{aligned}
& \mathrm{w} \text { ith }=\left(\begin{array}{ll}
1 & \mathrm{p}
\end{array}\right)_{1}+\mathrm{p}_{2} \text { and }
\end{aligned}
$$

$$
\begin{align*}
& \text { Y } \quad{ }^{3}\left(\mathrm{v}_{\mathrm{c}}^{0} \quad \mathrm{v}\right)^{5} \text { : }  \tag{9}\\
& \text { ct } \mathrm{a} ; \mathrm{b}
\end{align*}
$$

The follow ing properties can be proved [2]
 properly norm alized function $F$.

U pon denoting the one- and two-body velocity distributions at tim et as $f_{1}\left(v_{1} ; t\right)$ and $f_{2}\left(v_{1} ; v_{2} ; t\right)$, the follow ing exact equation of evolution holds:

$$
\begin{align*}
& f_{1}\left(v_{1} ; t+1\right)=\left(\begin{array}{lll}
1 & p) & 1 \\
N & f_{1}\left(v_{1} ; t\right)
\end{array}\right. \\
& +\frac{1}{3 N}\left[f_{1}\left(V_{x} ; v_{1 y} ; v_{1 z} ; t\right)+f_{1}\left(v_{1 x} ; \quad V_{y} ; v_{1 z} ; t\right)+f_{1}\left(v_{1 x} ; v_{1 y} ; \quad V_{z} ; t\right)\right] \\
& +p 1 \frac{2}{N} f_{1}\left(v_{1} ; t\right)+\frac{2}{N} \quad \frac{1}{2}^{Z} d^{3} v_{2}{ }^{Z} d^{3} \frac{1}{j j}{ }^{\prime \prime} \quad{\frac{v_{1}}{2} V_{2}^{2}}^{2} \\
& \mathrm{E} \frac{\mathrm{v}_{1}+\mathrm{v}_{2}}{2}+; \frac{\mathrm{V}_{1}+\mathrm{v}_{2}}{2} \text {; } \mathrm{t} \text { : } \tag{10}
\end{align*}
$$

For any function, the ansatz $f_{2}^{(e q)}\left(v_{1} ; v_{2}\right)=\left(v_{1}^{2}+v_{2}^{2}\right)$ gives a stationary solution to Eq. ( $(\underline{1} 0,1)$. H ow ever, in case of an isolated system w ith total energy $U$, the only adm issible solution to Eq. ( $\overline{\mathrm{O}})$ ) is the m icrocanonical density $\mathrm{w}(\mathrm{fvg}) /\left(v_{1}^{2}+:::+\mathrm{v}_{\mathrm{N}}^{2} \quad \mathrm{U}\right)$ ) [ [1] [ $]$, and the function becom es:

$$
\begin{equation*}
\mathrm{f}_{2}^{(\mathrm{eq})}\left(\mathrm{v}_{1} ; \mathrm{V}_{2}\right)=\frac{(3 \mathrm{~N}=2)}{(3(\mathrm{~N} \quad 2)=2)}(\mathrm{U})^{3} 1{\frac{\mathrm{v}_{1}^{2}+\mathrm{v}_{2}^{2}!\frac{3(\mathrm{~N} 2)}{2}}{\mathrm{U}}}^{1} \text {; } \tag{11}
\end{equation*}
$$

leading in tum to:

$$
\begin{equation*}
f_{1}^{(e q)}\left(\mathrm{V}_{1}\right)=\frac{(3 \mathrm{~N}=2)}{(3(\mathbb{N} \quad 1)=2)}(\mathrm{U})^{\frac{3}{2}} 1 \quad \frac{V_{1}^{2}!\frac{3(\mathbb{N} 1)}{2} 1}{U}: \tag{12}
\end{equation*}
$$

The latter is the nite N M axw ellBoltzm ann (MB) distribution [G]. In the
 fam iliar $G$ aussian form, $f_{1}^{(e q)}(v)=(=)^{3=2} \exp \left(v^{2}\right)$, with $=3 \mathrm{~N}=(2 \mathrm{U})$ (corresponding to an average $v_{a}^{2}$ of $U=N$ for all $a$ ).

I have carried out a com puter sim ulation of the evolution encoded in Eq. $(\underset{-1}{\overline{1}})$ in order to check whether the stationary distribution ( $(\underline{1} \overline{1})$ is also an asym ptotic solution, as expected (at least when $p>0$ ) from the ergodicity of kemel $(\underline{-1})$. First, I set $N=3$ and $U=0: 06$, with $p=0: 5$. Starting at any particular $m$ icrostate $w$ th energy $U$, I collect in a hystogram the values, at regular tim e intervals, of the three com ponents of particle-1 velocity (see Fig. 1 left). Indeed, this hystogram has, in the long run, the niteN M B form. This is indirect evidence that the simulation trajectory sam ples uniform ly, at leaste ectively ifnot literally, the 3N -dim ensionalhypersurface of energy $U$.

A fterw ards, I take $N=1000$ and $U=20$, and follow the evolution of the sam e hystogram as above, now starting from velocity values extracted at random from e.g. a uniform one-particle distribution of variance $U=(3 N)$. The long-run distribution of velocity no. 1 com pares well w ith a G aussian (F ig. 1 right), that is $w$ th the large N form of the M B distribution. In fact, also the instantaneous velocities of allparticles are asym ptotically distributed, for large $N$, according to the sam e $G$ aussian (see $F$ ig.2). This indicates that: 1) the vast $m$ a jority of points in the energy hypersurface is $m$ ade of \typical" states, i.e., $m$ icrostates that look $m$ ore or less sim ilar as far as low -order distributions like $f_{1}$ are concemed; and 2) them icrostate at which the evolution w as started is, indeed, untypical lबढ़].

For a given num ber $n$ of particles in box 1, the equilibrium probability density $W_{n}(u)$ of their totalenergy $u$ can be calculated exactly for $w(f v g) /$ $\left(v_{1}^{2}+:::+v_{N}^{2} \quad U\right):$

$$
\begin{equation*}
\left.W_{n}(\mathrm{u})=\frac{(3 \mathrm{~N}=2)}{(3 \mathrm{n}=2) \quad(3(\mathbb{N} \quad \mathrm{n})=2)} \mathrm{U} \quad{ }^{\left(\frac{3 N}{2}\right.} 1\right) \mathrm{u}^{\frac{3 n}{2}}{ }^{1}(\mathrm{U} \quad u)^{\frac{3(\mathrm{~N} n)}{2}} 1 ; \tag{13}
\end{equation*}
$$

that is, variable $u=U$ is beta-distributed $w$ ith an average of $n=N$. Of all $n-$ velocity $m$ icrostates, the fraction of those states whose energy lies betw een u and $\mathrm{u}+\mathrm{u}$ is $\mathrm{W}_{\mathrm{n}}(\mathrm{u}) \mathrm{u}(\mathrm{u} \quad \mathrm{u})$. In particular, the Boltzm ann entropy associated w th Eq. (1]

$$
\begin{equation*}
\ln W_{n}(u) \quad \frac{3 n}{2} \ln \frac{n}{u} \quad \frac{3(N \quad n)}{2} \ln \frac{N}{U} \quad n \quad \text { u } ; \tag{14}
\end{equation*}
$$

which, when including also the con gurational term ( $\left.\mathbf{\beta}_{1}\right)$ or ( the expression of the entropy of the ( $m$ onoatom ic) ideal gas.

In conclusion, I have introduced a stochastic process of the E hrenfest type which allow s one to found $m$ icroscopically the expression of the therm odynam ic entropy of an ideal gas, w thout relying on the hypothesis of equal a priori probability of all $m$ icrostates. R ather, the validity of the latter, at least in an e ective sense, follow s as an outcom e from the stochastic dynam ics itself. In them odynam ics, the Second Law requires the maxim ization of the total entropy $S$ under the given constraints (here, the total num ber of particles $N$ and the total energy $U$ of two ideal gases in grand-canonical contact) in order to nd the equilibrium state of an overall isolated system. In the present model, this very sam e prescription em erges naturally, when de ning entropy a la Boltzm ann, as the condition upon which the partition of $N$ and $U$ betw een the gases be, in the long-tim e regin $e$, the $m$ ost probable.

## FIGURECAPTIONS

Fig. 1 : N um erical sim ulation of Eq. (8)-1). H ystogram of velocity values for particle 1 ( 4,2 , and correspond to the x;y, and $z$ com ponent, respectively). Two distinct values of N are com pared, i.e., 3 (left) and 1000 (right), while $\mathrm{U}=\mathrm{N}=0: 02$ in both cases. A fter rejecting a total of $10^{4}$ collisions per particle (CPP), as m any as $\mathrm{N}_{\text {eq }}$ CPP are produced $\mathbb{N}_{\text {eq }}=10^{7}$ for $\mathrm{N}=3$ and $\mathrm{N}_{\text {eq }}=10^{6}$ for $\left.\mathrm{N}=1000\right)$. The p value was 0.5 , held xed during the sim ulation. D ata (in form of frequencies of occurrence) are grouped in bins of width $v=2 \mathrm{U}=\mathrm{N}=31$ (after equilibration, the hystogram is updated every 10 CPP). The full curve is the theoretical, nite N M B distribution per velocity com ponent, which, for $N={ }_{q}$, is appreciably di erent from the in nite-N lim it (i.e., the Gaussian $=\exp \left(\mathrm{v}^{2}\right)$, with $=3 \mathrm{~N}=(2 \mathrm{U})$ \{ broken curve in the left panel, full curve in the right panel).

Fig. 2 : Num erical sim ulation of Eq. ( end of the $\operatorname{sim} u l a t i o n ~ r u n ~ f o r ~ N ~=~ 1000 ~ a n d ~ U ~=~ 20 ~(s a m e ~ s y m b o l s ~$ and notation as in Fig.1). T he distribution of all-particle velocities at a given time strongly resembles the sam e G aussian as in Fig. (full curve). Bottom : D i erence between the above hystogram and this G aussian law .
