# The two dim ensional X Y m odel at the transition tem perature: A high precision M onte C arlo study 

$M$ artin $H$ asenbusch<br>D ipartim ento diF isica dell U níversita diP isa and $\mathbb{N} F N$, Largo B runo P ontecorvo 3, I-56127 P isa, Italy<br>em ail: $M$ artin $H$ asenbusch@ df.unipi.it

A bstract
W e study the classical $X Y$ (plane rotator) $m$ odelat the $K$ osterlitz$T$ houless phase transition. We sim ulate the model using the single cluster algorithm on square lattioes of a linear size up to $L=2048$. $W$ e derive the nite size behaviour of the second $m$ om ent correlation length over the lattice size $2 n d=L$ at the transition tem perature. T his new prediction and the analogous one for the helicity m odulus are confronted w ith our $M$ onte $C$ arlo data. This way $\kappa$ т $=1: 1199$ is con m ed as inverse transition tem perature. Finally we address the puzzle of logarithm ic corrections of the $m$ agnetic susceptibility at the transition tem perature.

## 1 Introduction

W e study the classical XY model on the square lattice. It is characterised by the action

$$
\begin{equation*}
S={ }_{x ;} s_{x} s_{x+\wedge} ; \tag{1}
\end{equation*}
$$

where $s_{x}$ is a unit vector $w$ th tw o real com ponents, $x=\left(\mathrm{x}_{1} ; \mathrm{x}_{2}\right)$ labels the sites on the square lattice, where $\mathrm{x}_{1} 2 \mathrm{f1;} 2 ;::: ; \mathrm{L}_{1} \mathrm{~g}$ and $\mathrm{x}_{2} 2 \mathrm{f1;} 2 ;:: ; \mathrm{L}_{2} \mathrm{~g}$,
gives the direction on the lattioe and ${ }^{\wedge}$ is a unit-vector in the -direction. W e consider periodic boundary conditions in both directions. The coupling constant has been set to $J=1$ and is the inverse tem perature. In our notation, the Boltzm ann-factor is given by $\exp (S)$. Som etim es in the literature the present $m$ odel is also called \plane rotatorm odel", while the nam e X Y m odel is used for a m odel w ith three spin-com ponents.
$K$ osterlitz and Thouless [1] have argued that the $X Y \mathrm{~m}$ odel undergoes a phase transition of in nite order. The low tem perature phase is characterised by a vanishing order param eter and an in nite correlation length , associated w th a line of Gaussian xed points. At a su ciently high tem perature pairs of vortices unbind and start to disorder the system resulting in a nite correlation length . In the neighbourhood of the transition tem perature $\mathrm{T}_{\mathrm{K}}$ t it behaves as

$$
\begin{equation*}
\text { , } a \exp \left(b t^{1=2}\right) \text {; } \tag{2}
\end{equation*}
$$

where $t=\left(T \quad T_{K T}\right)=T_{K T}$ is the reduced tem perature and $a$ and $b$ are nonuniversal constants. In subsequent work (e.g. refs. [2, 3]) the results of K osterlitz and Thouless had been con $m$ ed and the argum ents had been put on a $m$ ore rigorous basis.

This rather good theoretical understanding of the K osterlitz-T houless ( K T ) phase transition is contrasted by the fact that the veri cation of the theoretical predictions in M onte C arlo sim ulations had often been inconclusive or even in contradiction. Only starting from the early nineties, $M$ onte C arlo sim ulations allow ed to favour clearly the K T behaviour (2) over a pow er law / $t$, which is characteristic for a second order phase transition. A typical exam ple for such a work is ref. [4], where the XY m odel w ith the V illian action [5] was studied on lattioes of a size up to $1200^{2}$.

[^0]The di culties in $M$ onte $C$ arlo sim ulations $m$ ight be explained by logarithm ic corrections that are predicted to be present in the neighbourhood of the transition.

In the present paper we like to address tw o puzzling results presented in the literature that are related to this problem :
$T$ he tw o $m$ ost precise results $[6,7]$ for the transition tem perature $T_{K}$ of the X Y m odel di er by about 8 tim es the quoted errors.

The $m$ agnetic susceptibility is predicted to scale as $/ L^{2} \quad(\mathrm{ln} L)^{2 r}$ w ith $=1=4$ and $r=1=16$ at the transition tem perature. ${ }^{\mathrm{y}} \mathrm{H}$ ow ever the authors of refs. [10, 11] nd in their $M$ onte $C$ arlo sim ulations $r=0: 023(10)^{z}$ and $r=0: 0270(10)$, respectively.

In refs. [13, 7] the authors have show $n$ that $X Y$ m odels $w$ ith di erent actions share the universality class of the BCSOS model. This had been achieved by $m$ atching the renorm alization group ( $R G$ ) ow of the BCSOS m odelat the criticalpoint w ith that of the exact duals [14] of the X Y m odels using a particular $M$ onte $C$ arlo renorm alization group $m$ ethod. A s a result of this $m$ atching the estim ate $\mathrm{K}_{\mathrm{T}}=1: 1199(1)=1=0: 89294$ (8) for the XY m odel (1) has been obtained. ${ }^{x}$ The BCSOS m odel is equivalent w th the six-vertex $m$ odel [15]. T he exact result for the correlation length of the sixvertex $m$ odel $[16,17,18]$ show s the behaviour ofeq. (2) predicted by the K T theory. Them ain advantage of the $m$ atching approach is that the logarithm ic corrections and in particular also subleading logarithm ic corrections are the sam e in the XY m odel and the BCSO S m odel. ${ }^{1}$

In a m ore standard approach, O lsson [6] and Schultka and M anousakis [19] have studied the nite size behaviour of the helicity m odulus arriving at the estim ates $1={ }_{\text {к }}=0: 89213(10)$ and $1={ }_{\mathrm{K} ~}=0: 89220$ (13), respectively.

[^1]These authors studied lattioe sizes up to $L=256$ and $L=400$, respectively. W hile in their approach leading logarithm ic corrections are taken properly into account, subleading logarithm ic corrections are m issed. T his m ight explain the m issm atch of the results for the transition tem perature. H ere we shall resolve this discrepancy by brute foroe: W e study the helicily m odulus (and in addition the second $m$ om ent correlation length) on lattioes up to $\mathrm{L}=2048$.

H aving an accurate estim ate of $\mathrm{T}_{\mathrm{K}} \mathrm{T}$ and num erical results for large lattice sizes at hand, we then study the scaling of the $m$ agnetic susceptibility. H ere it tums out that the puzzling result for the value of the exponent $r$ can be resolved by taking into account subleading corrections.

A $m$ a jorpurpose of the present paper is to check the reliability ofstandard $m$ ethods to determ ine the tem perature of the transition and to verify its K T-nature. This aim smainly at m ore com plicated models, e.g. quantum $m$ odels or thin m s of three dim ensional system $\mathrm{s} w$ th nontrivial boundary conditions, where the duality transform ation is not possible, and hence the $m$ ethod of refs. $[13,7]$ can not be applied.

The outline of the paper is the follow ing: In the next section we give the de nitions of the observables that are studied in this paper: the helicity $m$ odulus, the second $m$ om ent correlation length and the $m$ agnetic susceptibility. Next we sum $m$ arise som e results from the literature on duality and the RG - ow at the K T transition. We re-derive the nite size behaviour of the helicity $m$ odulus at the transition tem perature. A long the sam e lines we then derive a new result for the dim ensionless ratio 2 nd $=\mathrm{L}$. T his is followed by $M$ onte $C$ arlo sim ulations using the single cluster algorithm for lattioes of a linear size up to $L=2048$ for $=1: 1199$ and $=1: 12091$. F itting the data for $=1: 1199$ we nd the behaviour of the helicity $m$ odulus and $2 n d=L$ predicted by the theory for the transition tem perature, while for $=1: 12091$ there is clear $m$ issm atch. F inally we analyse the data of the $m$ agnetic susceptibility at $=1: 1199$.

## 2 The observables

In this section we shall sum $m$ arise the de nitions of the observables that we have $m$ easured in our sim ulations. T he totalm agnetisation is de ned by

$$
\begin{equation*}
M={ }_{x}^{x} S_{x}: \tag{3}
\end{equation*}
$$

T he m agnetic susceptibility is then given as

$$
\begin{equation*}
=\frac{1}{\mathrm{~L}^{2}} \mathrm{M}^{2}: \tag{4}
\end{equation*}
$$

### 2.1 The second $m$ om ent correlation length 2 nd

$T$ he second $m$ om ent correlation length on a lattige of the size $L^{2}$ is de ned by

$$
\begin{equation*}
\text { 2nd }=\frac{1}{2 \sin (=\mathrm{L})} \quad \overline{\mathrm{F}} \quad 1^{1=2} \text {; } \tag{5}
\end{equation*}
$$

where is the m agnetic susceptibility as de ned above and

$$
\begin{equation*}
\mathrm{F}={\frac{1}{L^{2}}}_{\mathrm{x} ; \mathrm{y}}^{\mathrm{X}} \mathrm{hs}_{\mathrm{x}} s_{y} i \cos \left(2 \quad\left(\mathrm{y}_{1} \quad \mathrm{x}_{1}\right)=\mathrm{L}\right): \tag{6}
\end{equation*}
$$

$N$ ote that the results obtained in this paper only hold for the de nition of 2nd given in this subsection.

### 2.2 The helicity m odulus

The helicity m odulus gives the reaction of the system under a torsion [20]. To de ne the helicity m odulus we consider a system, where rotated boundary conditions in one direction are introduced: Forpairs x;y ofnearest neighbour sites on the lattioe $w$ th $x_{1}=L_{1}, y_{1}=1$ and $x_{2}=y_{2}$ the term $s_{x} s_{y}$ is replaced by

$$
s_{x} R s_{y}=s_{x}^{(1)} \cos () s_{x}^{(1)}+\sin () s_{x}^{(2)}+s_{x}^{(2)} \cos () s_{x}^{(2)} \sin () s_{x}^{(1)} \quad: \quad \text { (7) }
$$

T he helicity m odulus is then de ned by the second derivative of the free energy w th respect to at $=0$

$$
\begin{equation*}
=\frac{L_{1}}{L_{2}} \frac{@^{2} \ln Z()}{@ 2}=0 \tag{8}
\end{equation*}
$$

$N$ ote that we have skipped a factor one over tem perature in our de nition of the helicity modulus to obtain a dim ensionless quantity. It is easy to write the helicity m odulus as an observable of the system at $=0$ [21]. For $\mathrm{L}_{1}=\mathrm{L}_{2}=\mathrm{L}$ we get

$$
\begin{equation*}
=\frac{L^{2}}{}{ }^{D} s_{x} s_{x+1}{ }^{E} \frac{2}{L^{2}} s_{x}^{(1)} s_{x+1}^{(2)} s_{x}^{(2)} s_{x+1}^{(1)}{ }^{2}: \tag{9}
\end{equation*}
$$

## 3 K T theory

In this section we sum $m$ arise results from the literature that are relevant for our num erical study and also derive a novel result for the nite size behaviour of the second $m$ om ent correlation length at the transition tem perature.

X Y m odels can be exactly m apped by a so called duality transform ation [14] into solid on solid (SO S) m odels. E.g. the X Y m odelw ith the action (1) becom es

$$
\begin{equation*}
Z_{X Y}^{S O S}={ }_{\text {fhg } X ;}^{X} I_{f_{f_{X}} h_{x+\wedge j}() ;} \tag{10}
\end{equation*}
$$

$w$ here the $I_{n}$ are $m$ odi ed Bessel functions and the $h_{x}$ are integer. $T$ he XY $m$ odelw ith V illian action [5] takes a sim pler form under duality:

$$
\begin{equation*}
\mathrm{Z}_{\mathrm{V}}^{\operatorname{sos}}={ }_{\mathrm{fhg}}^{\mathrm{x}} \exp \quad \frac{1}{2}_{\mathrm{x} ;}^{\mathrm{x}}\left(\mathrm{~h}_{\mathrm{x}} \mathrm{~h}_{\mathrm{x}+\wedge}\right)^{2} ; \tag{11}
\end{equation*}
$$

where the $h_{x}$ are integer again. This $m$ odel is also called discrete $G$ aussian (D G ) m odel. In the context of nite size scaling one should pay attention to the fact that the boundary conditions transform non-trivially under duality. E.g. periodic boundary conditions in the XY m odel require that in the SO S m odel one sum s over all integer shifts $\mathrm{h}_{1}$ and $\mathrm{h}_{2}$ at the boundaries in 1-and 2-direction, respectively.

It tumed out to be most convenient to study the K osterlitz-T houless phase transition using generalisations of SO S m odels (see e.g. refs. [2, 3]).

### 3.1 The S ine-G ordon m odel

The Sine-G ordon $m$ odel is de ned by the action

$$
\begin{equation*}
S_{S G}=\frac{1}{2}_{x ;}^{x}(x \quad x+\wedge)^{2} \quad z_{x}^{x} \cos (2 x) ; \tag{12}
\end{equation*}
$$

where the variables x are realnum bers. Forpositive values of $z$, the periodic potential favours $x$ close to integers. In particular, in the lim it $z!1$, we recover the D G -SOS m odel. In the lim it $z=0$ we get the G aussian model (or in the language of high energy physics, a free eld theory). The SineG ordon model (using cuto schem es di erent from the lattioe) can be used to derive the RG-ow associated with the KT phase transition. For >2= the coupling $z$ is irrelevant, while for $<2=$ it becom es relevant. To discuss the RG - ow it is convenient to de ne

$$
\begin{equation*}
x=\quad 2: \tag{13}
\end{equation*}
$$

The ow equations are derived in the neighbourhood of $(x ; z)=(0 ; 0)$. To leading order they are given by

$$
\begin{align*}
& \frac{@ z}{@ t}=x z+::: ;  \tag{14}\\
& \frac{@ x}{@ t}=\text { const } z^{2}+::: ; \tag{15}
\end{align*}
$$

where $t=\ln l$ is the logarithm of the length scale $l$ at which the coupling is taken. N ote that we consider a xed lattioe spacing and a running length scale l, while e.g. in ref. [3] the cuto scale is varied. This explains the opposite sign in the ow equations com pared w ith e.g. ref. [3]. The const in the equation above depends on the particular type of cut-0 that is used. C orrections ofo ( $z^{3}$ ) have been com puted in ref. [3] and con $m$ ed in ref. [22]. $H$ ere we are $m$ ainly interested in the nite size behaviour at the transition tem perature. Therefore the trajectory at the transition tem perature is of particular interest. It is characterised by the fact that it ends in $(x ; z)=$ $(0 ; 0)$. To leading order it is given by

$$
\begin{equation*}
x=\text { const }^{1=2} \quad z: \tag{16}
\end{equation*}
$$

It follow s that the RG - ow on the critical trajectory is given by

$$
\begin{equation*}
\frac{@ x}{@ t}=x^{2}: \tag{17}
\end{equation*}
$$

I.e. on the critical tra jectory

$$
\begin{equation*}
x=\frac{1}{\ln 1+C} ; \tag{18}
\end{equation*}
$$

where $C$ is an integration constant that depends on the in itial value $x_{i}$ of $x$ at $l=1$. Taking into account the next to leading order result of ref. [3] the ow on the critical trajectory becom es

$$
\begin{equation*}
\frac{@ x}{@ t}=x^{2} \quad \frac{1}{2} x^{3}:::: \tag{19}
\end{equation*}
$$

Im plicitly the solution is given by [3]

$$
\begin{equation*}
\ln l=\frac{1}{x} \quad \frac{1}{x_{i}} \quad \frac{1}{2} \ln \frac{1=x+1=2}{1=x_{i}+1=2} ; \tag{20}
\end{equation*}
$$

where now the initial value $x_{i}$ of $x$ takes the role of the integration constant. The authors of ref. [3] give an approxim ate solution of this equation that is valid for $\mathrm{x}_{\mathrm{i}} \gg \mathrm{x}$. This leads to corrections to eq. (18) that are proportional to $\ln \mathrm{jln} L j \mathrm{j} j \mathrm{ln} \mathrm{L}$ f. H ow ever, in our num erical sim ulations we are rather in a situation where $x_{i}$ and $x$ di er only by a sm all factor. Therefore we $m$ ake no attem pt to $t$ our data taking explicitly into account the last term of eq. (20).

An im portant result of ref. [3] is that corrections proportional to $\ln j \ln L j j \ln L \rho$ arise from the $R G$ - ow in the $(x ; z)$-plane and are not caused by som e additional $m$ arginal operators, which $m$ ight have di erent am plitudes in di erent $m$ odels. Therefore the two-param eter $m$ atching of refs. $[7,13]$ is su cient to take properly into account corrections proportional to ln jln Ljj근予 (and beyond).

### 3.2 F in ite size scaling of dim en sion less quantities

H ere we com pute the values of the helicity modulus and the ratio ${ }_{\text {nd }}=L$ at $\mathrm{T}_{\mathrm{K}}$ in the $\lim$ it $\mathrm{L}!1$ and leading $1=\ln \mathrm{L}$ corrections to it. Since for both quantities the coe cient of the order $z$ is vanishing, this can be achieved by com puting both quantities at $z=0$ (i.e. for the $G$ aussian $m$ odel) and plugging in the value of given by eq. (18).

### 3.2.1 T he helicity m odulus

The helicity m odulus can be easily expressed in term softhe SO S m odeldual to the XY m odel:

$$
\begin{equation*}
=\frac{\mathrm{L}_{2}}{\mathrm{~L}_{1}} \operatorname{hh}_{1}^{2} \mathrm{i}_{\mathrm{sos}} ; \tag{21}
\end{equation*}
$$

$w h e r e h_{1}$ is the shift at the boundary in the 1 -direction. In this form we can com pute the helicity $m$ odulus in the Sine-G ordon $m$ odel. To this end we have to com pute the free energy as a function of the boundary shifts $\mathrm{h}_{1} ; \mathrm{h}_{2}$ :

$$
\begin{equation*}
\mathrm{F}\left(\mathrm{~h}_{1} ; \mathrm{h}_{2}\right)=\ln \left(\mathrm{Z}\left(\mathrm{~h}_{1} ; \mathrm{h}_{2}\right)=\mathrm{Z}(0 ; 0)\right) ; \tag{22}
\end{equation*}
$$

where $\mathrm{Z}\left(\mathrm{h}_{1} ; \mathrm{h}_{2}\right)$ is the partition function of the system w ith a shift by $\mathrm{h}_{1}$ and $h_{2}$ at the boundaries in 1 and 2-direction, respectively. From the SG action (12) we directly read o that $F\left(h_{1} ; h_{2}\right)$ is an even function of $z$. Hence the leading $z$ dependent contribution is $O\left(z^{2}\right)$. H ence for our purpose the purely $G$ aussian result $z=0$ is su cient. For the action (12) at $z=0$ we get

$$
\begin{align*}
& Z\left(h_{1} ; h_{2}\right)=Z^{Z}[] \exp \frac{1}{2}_{x ;}^{x}(x \quad x+\wedge d)^{2} \\
& =\quad \mathrm{D}\left[\mathrm{l} \exp \frac{1}{2} \mathbb{L}_{1} \mathrm{~L}_{2}\left(\mathrm{~d}_{1}^{2}+\mathrm{d}_{2}^{2}\right)+{ }_{\mathrm{x}}^{\mathrm{x}}(\mathrm{x} \quad \mathrm{x}+\wedge)^{2}\right] \\
& =\exp \frac{1}{2} L_{1} L_{2}\left(d_{1}^{2}+d_{2}^{2}\right) \quad Z(0 ; 0) \\
& =\exp \frac{1}{2} \frac{\mathrm{~L}_{2}}{\mathrm{~L}_{1}} \mathrm{~h}_{1}^{2}+\frac{\mathrm{L}_{1}}{\mathrm{~L}_{2}} \mathrm{~h}_{2}^{2} \quad \mathrm{Z}(0 ; 0) ; \tag{23}
\end{align*}
$$

where we have de ned $d=h=L$. N ote that we have distributed the boundary shift along the lattice by a reparam etrisation of the eld:

$$
\begin{equation*}
x=\sim_{x}+x_{1} d_{1}+x_{2} d_{2} ; \tag{24}
\end{equation*}
$$

where ${ }^{x}$ is the original eld. It follow s

$$
\begin{equation*}
=\frac{\mathrm{L}_{2}}{\mathrm{~L}_{1}} \frac{\mathrm{P}}{\mathrm{~h}_{1} \exp } \frac{1}{2} \frac{\mathrm{~L}_{2}}{\mathrm{~L}_{1}} \mathrm{~h}_{1}^{2} \quad \mathrm{~h}_{1}^{2} \exp \frac{1}{2} \frac{\mathrm{~L}_{2}}{\mathrm{~L}_{1}} \mathrm{~h}_{1}^{2} \quad: \tag{25}
\end{equation*}
$$

A ltematively we m ight evaluate the helicity modulus in the spin-w ave lim it of the XY m odel on the original lattice. This is justi ed by the duality transform ation presented in ref. [2] in appendix D. H ere we are only interested in the G aussian lim it of them odel. Under duality the of the G aussian m odel transform sas $\sim=1=$. Secondly we have to take into account that
even though vortioes are not present in the lim it $z=0$, the periodicity of the $X Y \mathrm{~m}$ odel has to be taken into account for the boundary conditions. H ence, the proper spin-w ave (SW ) description of the XY $m$ odel on a nite lattice w ith periodic boundary conditions is

$$
\begin{equation*}
Z_{S W}={\underset{n_{1} ; n_{2}}{\mathrm{X}} \mathrm{~W}\left(\mathrm{n}_{1} ; \mathrm{n}_{2}\right) \mathrm{Z}(0 ; 0) ; ~ ; ~}_{\text {, }} \tag{26}
\end{equation*}
$$

where $n_{1}$ and $n_{2}$ count the $w$ indings of the $X Y$ - eld along the 1 and 2 direction respectively. In the $G$ aussian $m$ odel they are given by shifts by $2 \mathrm{n}_{1}$ and $2 \mathrm{n}_{2}$ at the boundaries. The corresponding weights are

$$
\begin{equation*}
\mathrm{W}\left(\mathrm{n}_{1} ; \mathrm{n}_{2}\right)=\exp \quad \frac{(2)^{2}}{2^{\sim}} \frac{\mathrm{L}_{2}}{\mathrm{~L}_{1}} \mathrm{n}_{1}^{2}+\frac{\mathrm{L}_{1}}{\mathrm{~L}_{2}} \mathrm{n}_{2}^{2} \quad: \tag{27}
\end{equation*}
$$

H ere we can easily introduce a rotation by the angle at the boundary:

$$
\begin{equation*}
\mathrm{Z}_{\mathrm{SW} ;}={ }_{\mathrm{n}_{1} ; \mathrm{m}_{2}}^{\mathrm{x}} \exp \frac{(2)^{2}}{2^{\sim}} \frac{\mathrm{L}_{2}}{\mathrm{~L}_{1}}\left[n_{1}+=(2)\right]^{2}+\frac{\mathrm{L}_{1}}{\mathrm{~L}_{2}} \mathrm{n}_{2}^{2} \quad \mathrm{Z}(0 ; 0): \tag{28}
\end{equation*}
$$

P lugging this result into the de nition (8) of the helicity m odulus we get

$$
\begin{equation*}
=\frac{1}{\sim} \frac{L_{2}}{L_{1}} \frac{n_{1} \exp \frac{\left(2 n_{1}\right)^{2}}{2^{\sim}} \frac{L_{2}}{L_{1}}}{L_{1}} \frac{h_{2} n_{1}}{\sim} \frac{L_{2}}{L_{1}} i_{2} i_{1} \exp \frac{\left(2 n_{1}\right)^{2}}{2^{\sim}} \frac{L_{2}}{L_{1}} \quad: \tag{29}
\end{equation*}
$$

In the literature often only $=1=\sim=$ is quoted and the (tiny) correction due to winding elds is ignored. W e have checked num erically that the results of eq. (25) and eq. (29) indeed coincide. H ere we are interested in the case of an $L^{2}$ lattice in the neighbourhood of $=2=$. O ne gets

$$
\begin{equation*}
L^{2} ; z=0=0: 63650817819:::+1: 001852182:::(\quad 2=)+::: \text { : } \tag{30}
\end{equation*}
$$

P lugging in the result (18) and identifying the lattioe size L w ith the scale at which the coupling is taken, we get

$$
\begin{equation*}
L^{2}, \text { tran sition }=0: 63650817819:::+\frac{0: 318899454:::}{\ln L+C}+::: \tag{31}
\end{equation*}
$$

C ontributions ofo ( $\mathrm{z}^{2}$ ) that we have ignored here are proportionalto $1=(\mathrm{ln} \mathrm{L}+$ C ) ${ }^{2}$ at the transition.

### 3.2.2 T he second m om ent correlation length

In this section we derive a result for the dim ensionless ratio 2 nd $=\mathrm{L}$ analogous to eq. (31) for the helicity $m$ odulus. To this end we have to com pute the X Y two-point correlation function as a series in $z$. For the lim it L! 1 , the result can be found in the literature. It is im portant to notice that sim ilar to the helicity m odulus $O(z)$ contributions to the correlation function vanish. I.e. also here the G aussian result is su cient for our purpose. The nontrivial task is to take properly into account the e ects of periodic boundary conditions on the nite lattice. The starting point of our calculation is the spin wave m odel (26). Follow ing the de nition (24), a di erence of variables $\tilde{x}_{\mathrm{x}}$ and $\tilde{y}_{\mathrm{y}}$ of the system w ith shifted boundary conditions can be rew ritten in term $s$ of the system w ithout shift:

$$
\tilde{x}^{\sim} \sim_{y}=x \quad y+p_{1} n_{1}\left(x_{1} y_{1}\right)+p_{2} n_{2}\left(\begin{array}{ll}
x_{2} & y_{2} \tag{32}
\end{array}\right)
$$

w ith $\mathrm{p}_{\mathrm{i}}=2=\mathrm{L}_{\mathrm{i}}$. U sing this results, the spin-spin product can be written as

$$
\begin{align*}
\boldsymbol{s}_{\mathrm{x}} \boldsymbol{s}_{\mathrm{y}} & \left.=<\exp \left(\mathrm{i}\left[\begin{array}{cc}
\tilde{x}_{x} & \left.\left.\tilde{y}_{\mathrm{y}}\right]\right) \\
& =<\exp \left(\mathrm{i}\left[\begin{array}{ll}
\mathrm{x} & \mathrm{y}
\end{array}\right]\right) \exp \left(i \left[\left[_ { 1 } \mathrm { n } _ { 1 } \left(\mathrm{x}_{1}\right.\right.\right.\right. \\
\mathrm{y}_{1}
\end{array}\right)+\mathrm{p}_{2} \mathrm{n}_{2}\left(\mathrm{x}_{2} \quad \mathrm{y}_{2}\right)\right]\right) ;(33
\end{align*}
$$

where we have interpreted $\sim_{x}$ as the angle of the spin $s_{x}$.
The expectation value in the spin-w ave lim it becom es

$$
\begin{align*}
& { }_{P}^{h s_{x} s_{y} i_{S W}=} \\
& \frac{n_{1} ; n_{2} W\left(n_{1} ; n_{2}\right) \operatorname{hexp}\left(i\left[x_{p} \quad{ }_{y}\right]\right) \dot{o}_{0 ; 0} \cos \left(p_{1} n_{1}\left(x_{1} \quad y_{1}\right)+p_{2} n_{2}\left(x_{2} \quad y_{2}\right)\right)}{n_{1} ; m_{2} W\left(n_{1} ; n_{2}\right)} ; \tag{34}
\end{align*}
$$

where $h:: i_{0 ; 0}$ denotes the expectation value in a system w th vanishing boundary shift. C on gurations with a winding (ie. w ith a shift in ~) give only $m$ inor contributions; E.g. W $(1 ; 0)=3: 487::: 10^{6}$ for an $L^{2}$ lattice at
$=2=$.
W e have com puted hexp (i[ $\left.\begin{array}{ll}x & y\end{array}\right]$ ) $i_{0 ; 0}$ num erically, using the lattice propagator. To this end, we have used lattioes up to $L=2048$. For details of this calculation see the appendix. The results for $\left\langle\mathrm{S}_{\mathrm{x}} \mathrm{S}_{\mathrm{y}}\right\rangle$ were plugged into the de nition (5) of the second $m$ om ent correlation length. Extrapolating the nite lattice results to L ! 1 gives

$$
\begin{equation*}
2 n d=L=0: 7506912:::+0: 66737:::(\quad 2=)+:::::: \tag{35}
\end{equation*}
$$

Inserting $\frac{1}{\ln \mathrm{~L}+\mathrm{C}}=(2=)$ for the critical trajectory, we obtain

$$
\begin{equation*}
\text { 2nd }=\mathrm{L}=0: 7506912:::+\frac{0: 212430:::}{\ln L+C}+::: \tag{36}
\end{equation*}
$$

$N$ ote that a sim ilar result for the exponential correlation length on a lattice w ith strip geom etry, i.e. an L 1 lattioe, can be found in the literature [23]:

$$
\begin{equation*}
\exp =L=2 \text { : } \tag{37}
\end{equation*}
$$

Inserting $\frac{1}{\ln \mathrm{~L}+\mathrm{C}}=(2=)$ into (37) gives

$$
\begin{equation*}
\exp =L=\frac{4}{-}+\frac{2}{\ln L+C}+::: \tag{38}
\end{equation*}
$$

at the K T transition. This prediction had been com pared w ith M onte C arlo results in ref. [24] for lattice sizes up to $L=64$.

It is interesting to note that the lim it

$$
\begin{equation*}
\lim _{\exp ; 1}!1 \quad \exp =\mathrm{L} \dot{z}_{\mathrm{z}=\mathrm{L}=\exp ; 1} \text {; } \tag{39}
\end{equation*}
$$

where exp; 1 is the exponential correlation length in the in nite volum e lim it in the high tem perature phase, is exactly known for any $\mathrm{z}=\mathrm{L}=$ exp;1 [25]. $N$ ote that this lim it corresponds to the RG tra jectory that ow s out of the point $(x ; z)=(0 ; 0)$, while the present study is concemed w ith the tra jectory that ows into $(x ; z)=(0 ; 0)$.

## 4 M onte C arlo S im ulations

W e have sm ulated the XY m odel at $=1: 1199$, which is the estim ate of ref. [7] for the inverse transition tem perature and $=1: 12091$ which is the estim ate of $O$ lsson [6] and consistent $w$ thin error-bars $w$ th the result of Schultka and $M$ anousakis [19]. For both values of , we have sim ulated square lattioes up to a linear lattioe size of $L=2048$. The sim ulations were perform ed w th the single cluster algorithm [26]. A m easurem ent was perform ed after 10 single chuster updates. In units of these $m$ easurem ents, the integrated autocorrelation tim e of the $m$ agnetic susceptibility is less than one for all our sim ulations.

Table 1: M onte C arlo results for the helicity $m$ odulus , the second $m$ om ent correlation length over the lattice size ${ }_{2 n d}=\mathrm{L}$ and the $m$ agnetic susceptibilly for two dim ensional X Y model on a square lattice of linear size $L$ at = 1:1199.

| L |  | 2nd $=\mathrm{L}$ |  |
| ---: | :--- | :--- | :---: |
| 16 | $0.72536(7)$ | $0.79953(17)$ | $133.011(9)$ |
| 32 | $0.70883(7)$ | $0.79231(18)$ | $452.114(31)$ |
| 64 | $0.69785(7)$ | $0.78701(18)$ | $1536.58(11)$ |
| 128 | $0.69001(7)$ | $0.78310(18)$ | $5220.99(36)$ |
| 256 | $0.68400(7)$ | $0.77977(19)$ | $17729.9(12)$ |
| 512 | $0.67926(6)$ | $0.77745(18)$ | $60185.8(4.0)$ |
| 1024 | $0.67544(7)$ | $0.77532(19)$ | $204160 .(15)$. |
| 2048 | $0.67246(10)$ | $0.77300(28)$ | $692146 .(74)$. |

For each lattice size and -value we have perform ed 5.000 .000 m easurem ents, except for $\mathrm{L}=2048$ were only 2.500 .000 m easurem ents were perform ed. W e have used our own implem entation of the G 05CAF random num ber generator of the NAG -library. For each run, we have discarded at least 10000 m easurem ents for equilibration. N ote that this ism ore than what is usually considered as safe. On a PC w th an A thlon XP 2000+ CPU the sim ulation of the $L=2048$ lattice at one value of took about 76 days.

In table 1 we have sum $m$ arised our results for the helicity modulus , the second $m$ om ent correlation length over the lattioe size $2 n d=L$ and the $m$ agnetic susceptibility at $=1: 1199$. In table 2 we give analogous results at $=1: 12091$.

First we tted the helicity m odulus w ith the ansatz

$$
\begin{equation*}
=0: 63650817819+\text { const= }(\mathrm{ln} L+C) ; \tag{40}
\end{equation*}
$$

where const and C are the free param eters of the $t$. N ote that $O\left((\mathrm{ln} L)^{2}\right)$ corrections that are due to e.g. the $O\left(z^{2}\right)$ contribution to are e ectively taken into account by the $t$ param eter C.A lso corrections [3] proportional to $\ln j \ln L j(\ln L)^{2}$ contribute to the value of $C$, since ln $j \ln L$ jvaries little for the values of $L$ that enter into the ts.

The results of the ts for $=1: 1199$ are sum $m$ arised in table 3 and for

Table 2: Sam e as table 1 but for $=1: 12091$.

| L |  | 2nd $=\mathrm{L}$ |  |
| ---: | :--- | :--- | :---: |
| 16 | $0.72695(7)$ | $0.80044(18)$ | $133.174(10)$ |
| 32 | $0.71059(7)$ | $0.79326(18)$ | $452.856(31)$ |
| 64 | $0.69982(7)$ | $0.78888(18)$ | $1540.31(11)$ |
| 128 | $0.69225(7)$ | $0.78464(18)$ | $5235.34(36)$ |
| 256 | $0.68629(7)$ | $0.78157(19)$ | $17794.7(12)$ |
| 512 | $0.68186(7)$ | $0.77951(19)$ | $60436.6(4.3)$ |
| 1024 | $0.67826(7)$ | $0.77733(20)$ | $205185 .(15)$. |
| 2048 | $0.67528(10)$ | $0.77547(28)$ | $696308 .(75)$. |

= 1:12091 in table 4. For $=1: 1199$ the ${ }^{2}=$ d.o.f. stays rather large even up to $L_{m}$ in $=512$. A lso the value of $C$ is increasing steadily $w$ ith increasing $\mathrm{L}_{\mathrm{m}}$ in . H ow ever this is not too surprising, since corrections that are not taken into account in our ansatz decrease slow ly w ith increasing $L$. H ow ever, the results for const approach the theoretical prediction 0:318899454::: as $\mathrm{L}_{\mathrm{m}}$ in increases. For $L_{m}$ in $=64$ and 128, the ${ }^{2}=$ d.o.f. for $=1: 12091$ is much larger than for $=1: 1199$. H ow ever for $L_{m}$ in $=256$ it becom es about one for $=1: 12091$. This should however be seen as a coincidence, since the value of const is increasing $w$ ith $L_{m}$ in and already for $L_{m}$ in $=64$ the value of const is larger than the value predicted by the theory.

W e conchude that our t results are consistent w th $=1: 1199$ being the inverse transition tem perature, while $=1: 12091$ is clearly ruled out. O ne should notige how ever that ts w ith ansatze like eq. (40) are problem atic, since corrections that are not included die out only very slow ly as the lattioe size is increased.
$N$ ext we tted the results for the second $m$ om ent correlation length $w$ ith an ansatz sim ilar to that used for the helicity $m$ odulus

$$
\begin{equation*}
\text { 2nd }=\mathrm{L}=0: 7506912:::+ \text { const= }(\mathrm{n} L+C): \tag{41}
\end{equation*}
$$

The results of these ts are sum $m$ arised in table 5 for $=1: 1199$ and table 6 for $=1: 12091$. In contrast to the helicity modulus, we get a sm all
${ }^{2}=$ d.o.f. already for $L_{m}$ in $=64$. $T$ his $m$ ight be partially due to the fact that the relative statistical accuracy of $2 n d=\mathrm{L}$ is less than that of the helic-

Table 3: Fits of the helicity m odulus at $=1: 1199 \mathrm{w}$ ith the ansatz (40). $D$ ata $w$ th $L=L_{m}$ in up to $L=2048$ have been included into the $t$.

| $\mathrm{L}_{\mathrm{m}}$ in | const | C | 2/d.o.f. |

ity m odulus. The result for const at $=1: 1199$ is quite stable as $\mathrm{L}_{\mathrm{m}}$ in is varied, and furtherm ore it is consistent w ith the theoretical prediction const $=0: 212430:::$ derived in this work. On the other hand, the $t$ results of const at $=1: 12091$ are clearly larger than the theoretical prediction and furtherm ore the value of const is even increasing as $L_{m}$ in is increased. These results are consistent w th the analysis of the helicity m odulus: W hile our results are consistent with = 1:1199 being the inverse transition tem perature,
= 1:12091 is clearly nuled out.

### 4.1 T he m agnetic susceptib ility

The magnetic susceptibility at the transition tem perature is predicted to behave as

$$
\begin{equation*}
=\text { const } \mathrm{L}^{2} \quad(\mathrm{ln} L)^{2 r}::: \text {; } \tag{42}
\end{equation*}
$$

w th $\mathrm{r}=1=16$ and const depends on the particularm odel. This result can be obtained e.g. by integration of

$$
\begin{equation*}
h S_{x} S_{y} i / R^{1=4}(\ln R)^{1=8} \tag{43}
\end{equation*}
$$

given in ref. [3] for the correlation function, where $R=j x j$ jeading corrections to eq. (42) are due to the integration constant in eq. (18):

$$
\begin{equation*}
=\text { const } L^{2} \quad(\mathrm{ln} L+C)^{2 r}:::: \tag{44}
\end{equation*}
$$

In ref. [10] Irving and $K$ enna have sim ulated the sam e m odel as studied in this work on lattices up to $L=256$. $U$ sing the ansatz (42), leaving $r$ as free param eter, they nd $r=0: 023(10)$, which is about half of the value predicted by the theory. Later Janke [11] repeated this analysis for the XY model with the V illian action and lattioes up to $\mathrm{L}=512$. He nds, also tting $w$ ith the ansatz (42), $r=0: 0270(10)$, which is consistent $w$ ith the result of Irving and $K$ enna.

H ere we shall check whether the value of $r$ changes as larger lattioe sizes are included into the $t$. To this end, we only discuss the data for $=1: 1199$. In table 7 we give results for ts w ith the ansatz (42), where we have taken $2 r$ as a free param eter. The ${ }^{2}=d . o . f$. is very large up to $L_{m}$ in $=256$. For $L_{m}$ in $=32$ our results for $2 r$ is slightly larger than that of refs. [10, 11]. A swe increase $L_{m}$ in also $2 r$ increases. However, even for $L_{m}$ in $=512$, the result for $2 r$ is by $m$ ore than 70 standard deviations sm aller than the value predicted by the KT theory.

N ext we checked whether this apparent discrepancy can be resolved by adding the leading correction predicted by the theory as free param eter to the $t$. In table 8 we give our results for ts w ith the ansatz (44), where we have xed $2 r=1=8$. We see that already for $L_{m}$ in $=128$ an acceptable ${ }^{2}=$ d.o.f. is reached.
F inally we perform ed ts w the ansatz (44), where now also $2 r$ is used as free param eter. The results are sum $m$ arised in table 9. The ${ }^{2}=$ d.o.f. becom es acceptable for $L_{m}$ in starting from $L_{m}$ in $=128$. $N$ ow the $t$ results for 2 r for $\mathrm{L}_{\mathrm{m}}$ in $=128$ and 256 are consistent w ithin the statistical errors w th the theoretical prediction.

W e conclude that the apparent discrepancy w ith the K T -theory that was observed in refs. $[10,11]$ can be resolved by adding a correction term, which is predicted by the K T theory, to eq. (42).

Table 7: F its of the m agnetic susceptibility at $=1: 1199 \mathrm{w}$ th the ansatz (42). D ata w ith $\mathrm{L}=\mathrm{L}_{\mathrm{m}}$ in up to $\mathrm{L}=2048$ have been included into the $t$.

| $\mathrm{L}_{\mathrm{m}}$ in | const | $2 r$ | ${ }^{2}=$ d.o.t. |

| 256 | $0.857(38)$ | $2.5(1.1)$ | $0.112(14)$ | 0.01 |

## 5 Sum $m$ ary and Conclusions

W e have studied the nite size behaviour of various quantities at the $K$ osterlitz$T$ houless transition of the tw o-dim ensionalX Y m odel. For the helicity m odulus the value at the K osterlitz-T houless transition in the $\mathrm{L}!1$ lim it and the leading logarithm ic corrections to it are exactly known. Here, we have derived the analogous result (36) for the second $m$ om ent correlation length over the lattioe size ${ }_{2 n d}=\mathrm{L}$ :

$$
2 \mathrm{nd}=\mathrm{L}=0: 7506912:::+\frac{0: 212430:::}{\ln \mathrm{L}+\mathrm{C}}+:::
$$

W e have perform ed M onte Carlo simulations of the 2D XY model at = 1:1199 and = 1:12091, which are the estim ates of the transition tem perature of ref. [7] and ref. [6], respectively. U sing the single cluster algorithm we sim ulated lattioes of a size up to $2048^{2}$, which is by a factor of $5^{2}$ larger than the lattioes that had been studied in ref. [6]. A nalysing our data for the helicity m odulus and the ratio 2 nd $=\mathrm{L}$ we con $\mathrm{m}=1: 1199$ as transition tem perature, while $=1: 12091$ is clearly ruled out.

F itting M onte C arlo data w ith the ansatze $(40,41)$ is certainly a reasonablem ethod to locate the transition tem perature and to verify the $K$ osterlitz$T$ houless nature of the transition. H ow ever one should note that the large values of $=$ d.o.f. of our ts and the running of the $t$ param eter $C$ with the $s m$ allest lattice size $L_{m}$ in that is included into the $t s$, indicate that subleading corrections that are not taken into account in the ansatze $(40,41)$ are still large for the lattioe sizes that we have studied. Since these corrections decay only logarithm ically w th the lattice size, it is di cult to estim ate the system atic errors that are due to these corrections.

F inally we studied the nite size scaling of the m agnetic susceptibility. At the transition it should behave like $/ L^{2} \quad \ln L^{2 r}$ with $=1=4$ and $r=$ $1=16$. H ow ever, tting num erical data, the authors of refs. [10, 11] found $r=0: 023(10)$ and $r=0: 0270(10)$, respectively. Inchuding larger lattioes into the ts, our result for $r m$ oves tow ard the predicted value. Extending the ansatz to / $L^{2}(\mathrm{n} L+C)^{2 r}$, where C is an additional free param eter consistent w ith the theory, the apparent contradiction is com pletely resolved: For a $m$ in im al lattice size $L_{m \text { in }}=256$ that is included into the $t$, we get $r=0: 056(7)$.

## 6 A cknow ledgem ent

I like to thank Ettore $V$ icarifor discussions and a critical reading of the draft. Som e of the sim ulations have been perform ed at the $H$ um boldt-U niversitat zu B erlin, where I stayed as guest in O ctober 2004. I like to thank V incenzo A lba for spotting the error in $=\mathrm{L}$ given in tables 1 and 2 that has been corrected in the present version of the paper.

## 7 A ppendix: The correlation function at $z=0$

H ere we com pute the spin-spin correlation function for $z=0$, i.e. for the spin w ave approxim ation, for nite lattioes w ith periodic boundary conditions.

To this end letus rst sum $m$ arise a few basic form ula on $m$ ulti-dim ensional G aussian integrals as they can be found in text books on eld theory.

O ur starting point is the generating functional

$$
\begin{equation*}
\frac{1}{Z}^{Z} D\left[\exp \quad \frac{1}{2}(; A)+i k \quad=\exp \quad \frac{1}{2}\left(k ; A^{1} k\right)\right. \tag{45}
\end{equation*}
$$

w here

$$
\begin{equation*}
\frac{1}{2}(; A)=\frac{1}{2}_{x ; y}^{X} A_{x y} x y_{y}=\frac{1}{2}_{x ;}{ }^{h}(x \quad x+\wedge)^{2}+m^{2}{\underset{x}{2}}_{i}^{i} \tag{46}
\end{equation*}
$$

is the action of the $G$ aussian $m$ odel on a square lattioe and the partition function is given by

$$
\begin{equation*}
\mathrm{Z}=\mathrm{D}\left[\mathrm{l} \exp \frac{1}{2}(; \mathrm{A})\right. \tag{47}
\end{equation*}
$$

w ith

$$
\begin{equation*}
\mathrm{Z}[]^{\mathrm{Y}} \mathrm{Z}^{\mathrm{Z}} \mathrm{~d}_{\mathrm{x}}: \tag{48}
\end{equation*}
$$

For a square lattioe w ith periodic boundary conditions A ${ }^{1}$ can be easily obtained using a Fourier transform ation :

$$
\begin{align*}
\left(A^{1}\right)_{x y} & ={\frac{1}{L^{2}}}^{x} \frac{e^{i p(x y)}}{\hat{p}^{2}+m^{2}} ; \\
\hat{p}^{2} & =42 \operatorname{cosp}_{1} \quad 2 \operatorname{cosp}_{2} ; \tag{49}
\end{align*}
$$

where the $p_{i}, i=1 ; 2$ are summed over the values $f 0 ;::: 1 \mathrm{~L} \quad 1 g_{p} \quad(2=L)$. Here we are interested in the $m$ assless lim it m! 0 . N ote that for ${ }_{x} k_{x}=0$ $\left.{ }_{P}^{\text {the contributions to }(k ; A ~}{ }^{1} k\right)$ from $\left(\mathrm{p}_{1} ; \mathrm{P}_{2}\right)=(0 ; 0)$ exactly cancel, while for ${ }_{x} k_{x} \in 0$, in the lim it $m!~ 0$, the right hand side of eq. (45) vanishes due to the divergent zero-m om entum contributions to ( $k ; A^{1} k$ ). H enœ we get:

$$
\begin{align*}
& \lim _{m!} \frac{1}{Z}^{Z} D[] \exp \quad \frac{1}{2}(; A)+i k \tag{50}
\end{align*}
$$

w ith

$$
\begin{equation*}
C_{x y}={\frac{1}{L^{2}}}_{p \in 0}^{X} \frac{e^{i p(x y)}}{p^{2}}: \tag{51}
\end{equation*}
$$

N ote that adding a constant to $\mathrm{C}_{\mathrm{XY}}$ does not change the result. H ere we have chosen this constant such that $\mathrm{C}_{\mathrm{xx}}=0$.

N ow we are in the position to com pute the two-point correlation function (34) required for the com putation of the second $m$ om ent correlation length (5):

$$
\operatorname{hexp}\left(i\left[\begin{array}{ll}
\mathrm{x} & \mathrm{y} \tag{52}
\end{array}\right]\right) \mathrm{i}_{00}=\exp \left[\mathrm{C}_{\mathrm{xy}}\right]:
$$

D ue to translational invariance, it is su cient to com pute $g(x)=C_{(0 ; 0) ; x}$, for all lattice sites $x$. Em ploying the re ection sym $m$ etry of the lattice $w$ th respect to various axis the num ber of sites can be further reduced by a constant factor. Still, the direct im plem entation of eq. (51) would results in a com putationale ort / $V^{2}$ for the calculation of ${ }_{2 n d}$, where $V$ is the num ber of lattice points. A $m$ ore e cient $m$ ethod is discussed below.
$F$ irst we com pute $g(x)$ w th $x=\left(x_{1} ; 0\right)$ for $x_{1}>0$ :

$$
\begin{equation*}
g\left(x_{1} ; 0\right)={\frac{1}{L^{2}}}_{p_{1} \in 0}^{x} Q\left(p_{1}\right)\left[e^{i p_{1} x_{1}} \quad 1\right] \tag{53}
\end{equation*}
$$

w ith

$$
\begin{equation*}
Q\left(p_{1}\right)={ }_{p_{2}}^{x} \frac{1}{p^{2}}: \tag{54}
\end{equation*}
$$

I.e. these $\mathrm{g}(\mathrm{x})$ can be com puted w th an e ort proportional to V .
$N$ ext we notioe that $g(x)$ satis es Poisson's equation (see e.g. ref. [27] and refs. therein):

$$
\begin{aligned}
& 4 g(x) \quad g(x \quad(1 ; 0)) \quad g(x+(1 ; 0)) \quad g(x \quad(0 ; 1)) \quad g(x+(0 ; 1))=
\end{aligned}
$$

In principle, the rem aining $g(x)$ can now be com puted recursively, using eq. (55). F irst one has to note that $\mathrm{g}\left(\mathrm{x}_{1} ; 1\right)=\mathrm{g}\left(\mathrm{x}_{1} ; 1\right)$, where we identify L 1 w th 1 , for sym $m$ etry reason. Therefore

$$
\begin{equation*}
g\left(x_{1} ; 1\right)=\frac{1}{2}\left[4 g\left(x_{1} ; 0\right) \quad g\left(x_{1} \quad 1 ; 0\right) \quad g\left(x_{1}+1 ; 0\right)+L^{2}\right]: \tag{56}
\end{equation*}
$$

Then for $x_{2}>1$ one gets

$$
\begin{align*}
& g\left(x_{1} ; x_{2}\right)=4 g\left(x_{1} ; x_{2} \quad 1\right) \\
& g\left(\begin{array}{lll}
x_{1} & 1 ; x_{2} & 1
\end{array}\right) \quad g\left(x_{1}+1 ; x_{2} \quad 1\right) \quad g\left(x_{1} ; x_{2} \quad 2\right)+L^{2}: \tag{57}
\end{align*}
$$

U nfortunately, rounding errors rapidly accum ulate, and the recursion is useless, at least when using double precision oating point numbers, for the lattige sizes we are aim ing at.

Instead, we have used an iterative solver to solve eq. (55). W e im posed $g\left(x_{1} ; 0\right)=g\left(0 ; x_{1}\right)$ obtained from eq. (53) as D irichlet boundary conditions. As solver we have used a successive overrelaxation (SO R) algorithm . W ith the optim al overrelaxation param eter, the com putational e ort is proportional to $L^{3}$. W e controlled the num erical accuracy of the solution by com puting $g(x)$ from eq. (51) for a few distances $x$. Since we could extract su ciently accurate results for the $\lim \mathrm{t} \mathrm{L}$ ! 1 from lattioe sizes up to $\mathrm{L}=$ 2048, we did not im plem ent m ore advanced solvers like e.g. m ultigrid solvers.
