#### Abstract

Stirling approximation of the factorials and multinominal coefficients are generalized based on the one-parameter ( $\kappa$ ) deformed functions introduced by Kaniadakis [Phys. Rev. E 66 (2002) 056125]. We have obtained the relation between the $\kappa$-generalized multinominal coefficients and the $\kappa$-entropy by introducing a new $\kappa$-product operation.

Keywords: $\kappa$-entropy, $\kappa$-product, Stirling approximation, multinominal coefficients

[^0]
## I. INTRODUCTION

As is well-known in the fields of statistical mechanics, Ludwig Boltzmann clarified the concept of entropy. He considered a macroscopic system consists of a large number of particles. Each particle is assumed to be in one of the energy level $E_{i}(i=1, \ldots, k)$ and the number of particles in the level $E_{i}$ is $n_{i}$. The total number of particles is then $n=\sum_{i=1}^{k} n_{i}$ and the total energy of a macrostate is $E=\sum_{i} n_{i} E_{i}$. The number of ways of arranging $n$ particles in $k$ energy levels such that each level has $n_{1}, n_{2}, \ldots, n_{k}$ particles are the multinominal coefficients

$$
\left[\begin{array}{c}
n  \tag{1}\\
n_{1} \cdots n_{k}
\end{array}\right] \equiv \frac{n!}{n_{1}!\cdots n_{k}!},
$$

which is proportional to the probability of the macrostates if all microscopic configurations are assumed to be equally likely. In the thermodynamic limit $n$ increasing to infinity, we consider the relative number $p_{i} \equiv n_{i} / n$ as the probability of the particle occupation of a certain energy level $E_{i}$. In order to find the most probable macrostate, Eq. (1) is maximized under a certain constraint. The Stirling approximation of the factorials leads to

$$
\ln \left[\begin{array}{c}
n  \tag{2}\\
n_{1} \cdots n_{k}
\end{array}\right] \approx n S^{\mathrm{BGS}}\left(\frac{n_{1}}{n}, \ldots, \frac{n_{k}}{n}\right)
$$

where

$$
\begin{equation*}
S^{\mathrm{BGS}}\left(\frac{n_{1}}{n}, \ldots, \frac{n_{k}}{n}\right) \equiv-\sum_{i=1}^{k} p_{i} \ln \left(p_{i}\right), \tag{3}
\end{equation*}
$$

is the Boltzmann-Gibbs-Shannon (BGS) entropy.
Quite recently one of the authors (H.S.) has shown one-parameter generalizations of Gauss' law of error [1], Stirling approximation 2], and multinominal coefficients [3] based on the Tsallis $q$-deformed functions and associated multiplication operation ( $q$-product) [4, 5]. These mathematical structures are quite fundamental for the basis of any generalization of statistical physics as in the standard statistical physics. In particular Ref. [3] has shown that the one-to-one correspondence between the $q$-multinominal coefficient and Tsallis $q$-entropy [6, 7, 8], i.e., the one-parameter (q) generalization of Eq. (22).

On the other hand, Kaniadakis [9, 10, 11] has proposed the $\kappa$-generalized statistical mechanics based on the $\kappa$-deformed function, which is another type of one-parameter deformations for the exponential and logarithmic functions. Based on the $\kappa$-deformed functions and
the associated product operation ( $\kappa$-product) we have already shown the $\kappa$-generalization of Gauss' law of error [12].

In this work we show the $\kappa$-generalizations of the Stirling approximation and the relation between the $\kappa$-multinominal coefficient and $\kappa$-entropy. In the next section the $\kappa$-factorial is introduced based on the $\kappa$-product. Then the $\kappa$-generalization of the Stirling approximation is obtained. We see that the naive approach fails in order to relate the $\kappa$-multinominal coefficients with the $\kappa$-entropy. In order to overcome this difficulty, we introduce a new kind of $\kappa$-product in section 3 and show the explicit relation between the $\kappa$-multinominal coefficients and the $\kappa$-entropy. The final section is devoted to our conclusions.

## II. $\kappa$-STIRLING APPROXIMATION

Let us begin with the brief review of the $\kappa$-factorial and its Stirling approximation. The $\kappa$-generalized statistics [9, 10, 11] is based on the $\kappa$-entropy

$$
\begin{equation*}
S_{\kappa} \equiv-\sum_{i} p_{i} \ln _{\{\kappa\}}\left(p_{i}\right) \tag{4}
\end{equation*}
$$

where $\kappa$ is a real parameter in the range $(-1,1)$, and the $\kappa$-logarithmic function is defined by

$$
\begin{equation*}
\ln _{\{\kappa\}}(x) \equiv \frac{x^{\kappa}-x^{-\kappa}}{2 \kappa} \tag{5}
\end{equation*}
$$

The inverse function is the $\kappa$-exponential function defined by

$$
\begin{equation*}
\exp _{\{\kappa\}}(x) \equiv\left[\sqrt{1+\kappa^{2} x^{2}}+\kappa x\right]^{\frac{1}{\kappa}} \tag{6}
\end{equation*}
$$

In the limit of $\kappa \rightarrow 0$ the both $\kappa$-logarithmic and $\kappa$-exponential functions reduce to the standard logarithmic and exponential functions, respectively. We thus see that $S_{\kappa}$ reduces to the BGS entropy of Eq. (3) in the limit of $\kappa \rightarrow 0$.

Based on the above $\kappa$-deformed functions, the $\kappa$-product is defined by

$$
\begin{align*}
x \otimes y & \equiv \exp _{\{\kappa\}}\left[\ln _{\{\kappa\}}(x)+\ln _{\{\kappa\}}(y)\right] \\
& =\left[\left(\frac{x^{\kappa}-x^{-\kappa}}{2}\right)+\left(\frac{y^{\kappa}-y^{-\kappa}}{2}\right)+\sqrt{1+\left\{\left(\frac{x^{\kappa}-x^{-\kappa}}{2}\right)+\left(\frac{y^{\kappa}-y^{-\kappa}}{2}\right)\right\}^{2}}\right]^{\frac{1}{\kappa}} \tag{7}
\end{align*}
$$

which reduces to the standard product $x \cdot y$ in the limit of $\kappa \rightarrow 0$. Similarly the $\kappa$-division is defined by

$$
\begin{align*}
& x \oslash \\
& \oslash_{\kappa} y \equiv \exp _{\{\kappa\}}\left[\ln _{\{\kappa\}}(x)-\ln _{\{\kappa\}}(y)\right]  \tag{8}\\
&=\left[\left(\frac{x^{\kappa}-x^{-\kappa}}{2}\right)-\left(\frac{y^{\kappa}-y^{-\kappa}}{2}\right)+\sqrt{1+\left\{\left(\frac{x^{\kappa}-x^{-\kappa}}{2}\right)-\left(\frac{y^{\kappa}-y^{-\kappa}}{2}\right)\right\}^{2}}\right]^{\frac{1}{\kappa}},
\end{align*}
$$

which reduces to the standard division $x / y$ in the limit of $\kappa \rightarrow 0$. By utilizing this $\kappa$-product, the $\kappa$-factorial $n!{ }_{\kappa}$ with $n \in \mathbb{N}$ is defined by

$$
\begin{align*}
n! & \equiv \underset{\kappa}{\otimes} \underset{\kappa}{\otimes} \underset{\kappa}{\otimes} \cdots \underset{\kappa}{\otimes} n \\
& =\left[\sum_{k=1}^{n}\left(\frac{k^{\kappa}-k^{-\kappa}}{2}\right)+\sqrt{\left\{\sum_{k=1}^{n}\left(\frac{k^{\kappa}-k^{-\kappa}}{2}\right)\right\}^{2}+1}\right]^{\frac{1}{\kappa}}=\exp _{\{\kappa\}}\left[\sum_{k=1}^{n} \ln _{\{\kappa\}}(k)\right] . \tag{9}
\end{align*}
$$

Now we come to the Stirling approximation of the $\kappa$-factorials. For sufficient large $n$, the summation is well approximated with the integral as follows.

$$
\begin{equation*}
\ln _{\{\kappa\}}(n!\kappa)=\sum_{k=1}^{n} \ln _{\{\kappa\}}(k) \approx \int_{0}^{n} d x \ln _{\{\kappa\}}(x)=\frac{n^{1+\kappa}}{2 \kappa(1+\kappa)}-\frac{n^{1-\kappa}}{2 \kappa(1-\kappa)} \tag{10}
\end{equation*}
$$

Clearly this reduces to the standard Stirling approximation as

$$
\begin{equation*}
\lim _{\kappa \rightarrow 0} \ln _{\{\kappa\}}\left(n!_{\kappa}\right) \approx \lim _{\kappa \rightarrow 0} \frac{n}{1-\kappa^{2}}\left\{\ln _{\{\kappa\}}(n)-\frac{n^{\kappa}+n^{-\kappa}}{2}\right\}=n(\ln n-1) \tag{11}
\end{equation*}
$$

Next the $\kappa$-multinominal coefficient is defined by utilizing the $\kappa$-product and $\kappa$-division as follows

$$
\left[\begin{array}{c}
n  \tag{12}\\
n_{1} \cdots n_{k}
\end{array}\right]_{\kappa} \equiv n!_{\kappa} \oslash_{\kappa}\left(n_{1}!_{\kappa} \underset{\kappa}{\otimes} \cdots \underset{\kappa}{\otimes} n_{k}!_{\kappa}\right),
$$

where we assume

$$
\begin{equation*}
n=\sum_{i=1}^{k} n_{i} \tag{13}
\end{equation*}
$$

In the limit of $\kappa \rightarrow 0$, Eq. (12) reduces to the standard multinominal coefficient of Eq. (11).
Let us try to relate the $\kappa$-multinominal coefficients with the $\kappa$-entropy. Taking the $\kappa$ logarithm of Eq. (12) and applying the $\kappa$-Stirling approximation leads to

$$
\ln _{\{\kappa\}}\left[\begin{array}{c}
n  \tag{14}\\
n_{1} \cdots n_{k}
\end{array}\right]_{\kappa}=\ln _{\{\kappa\}}\left(n!_{\kappa}\right)-\sum_{i=1}^{k} \ln _{\{\kappa\}}\left(n_{i}!_{\kappa}\right),
$$

we then obtain

$$
\ln _{\{\kappa\}}\left[\begin{array}{c}
n  \tag{15}\\
n_{1} \cdots n_{k}
\end{array}\right]_{\kappa} \approx \frac{n^{1+\kappa}}{2 \kappa(1+\kappa)}\left\{1-\sum_{i=1}^{k}\left(\frac{n_{i}}{n}\right)^{1+\kappa}\right\}+\frac{n^{1-\kappa}}{2 \kappa(1-\kappa)}\left\{\sum_{i=1}^{k}\left(\frac{n_{i}}{n}\right)^{1-\kappa}-1\right\}
$$

From this relation, we see that the above naive approach fails. Since the r.h.s. consists of the two terms with different factors (one is proportional to $n^{1+\kappa} /(1+\kappa)$ and the other is proportional to $\left.n^{1-\kappa} /(1-\kappa)\right)$, this cannot be proportional to the $\kappa$-entropy, which can be written by

$$
\begin{align*}
S_{\kappa}\left(\frac{n_{1}}{n}, \ldots, \frac{n_{k}}{n}\right) & \equiv-\sum_{i=1}^{k}\left(\frac{n_{i}}{n}\right) \ln _{\{\kappa\}}\left(\frac{n_{i}}{n}\right) \\
& =\frac{1}{2 \kappa}\left\{1-\sum_{i=1}^{k}\left(\frac{n_{i}}{n}\right)^{1+\kappa}\right\}+\frac{1}{2 \kappa}\left\{\sum_{i=1}^{k}\left(\frac{n_{i}}{n}\right)^{1-\kappa}-1\right\} . \tag{16}
\end{align*}
$$

## III. INTRODUCING A NEW $\kappa$-PRODUCT

In order to overcome the above difficulty, we introduce another $\kappa$-generalization of the products based on the following function defined by

$$
\begin{equation*}
u_{\{\kappa\}}(x) \equiv \frac{x^{\kappa}+x^{-\kappa}}{2}=\cosh (\kappa \ln (x)) . \tag{17}
\end{equation*}
$$

We here call it the $\kappa$-generalized unit function since $\lim _{\kappa \rightarrow 0} u_{\{\kappa\}}(x)=1$. The basic properties of $u_{\{\kappa\}}(x)$ are as follows.

$$
\begin{align*}
& u_{\{\kappa\}}(x)=u_{\{\kappa\}}\left(\frac{1}{x}\right),  \tag{18}\\
& u_{\{\kappa\}}(x) \geq 1, \text { because } u_{\{\kappa\}}(x)-1=\frac{\left(x^{\frac{\kappa}{2}}-x^{-\frac{\kappa}{2}}\right)^{2}}{2} \geq 0 . \tag{19}
\end{align*}
$$

The inverse function of $u_{\{\kappa\}}(x)$ can be defined by

$$
\begin{equation*}
u_{\{\kappa\}}^{-1}(x) \equiv\left[\sqrt{x^{2}-1}+x\right]^{\frac{1}{\kappa}}, \quad(x \geq 1) \tag{20}
\end{equation*}
$$

In Ref. 13], the canonical partition function associated with the $\kappa$-entropy is obtained in terms of this $u_{\{\kappa\}}$ function. Note that

$$
\begin{equation*}
\ln _{\{\kappa\}}(x)=\frac{x^{\kappa}-x^{-\kappa}}{2 \kappa}=\frac{1}{\kappa} \sinh (\kappa \ln (x)), \tag{21}
\end{equation*}
$$

the two kinds of the $\kappa$-deformed functions $\left(\ln _{\{\kappa\}}(x)\right.$ and $\exp _{\{\kappa\}}(x) ; u_{\{\kappa\}}(x)$ and $\left.u_{\{\kappa\}}^{-1}(x)\right)$ are thus associated each other. This can be seen from the following relations

$$
\begin{align*}
\sqrt{1+\kappa^{2} \ln _{\{\kappa\}}^{2}(x)} & =u_{\{\kappa\}}(x),  \tag{22}\\
u_{\{\kappa\}}^{-1}\left(\sqrt{1+\kappa^{2} x^{2}}\right) & =\exp _{\{\kappa\}}(x), \quad \text { for } x \geq 0 \tag{23}
\end{align*}
$$

Now by utilizing these functions, a new $\kappa$-product is defined by

$$
\begin{align*}
x \odot & \underset{\kappa}{\oplus}
\end{align*} \equiv_{\{\kappa\}}^{-1}\left[u_{\{\kappa\}}(x)+u_{\{\kappa\}}(y)\right] .
$$

Similarly the corresponding $\kappa$-division is defined by

$$
\begin{align*}
x \odot_{\kappa} y & \equiv u_{\{\kappa\}}^{-1}\left[u_{\{\kappa\}}(x)-u_{\{\kappa\}}(y)\right] \\
& =\left[\left(\frac{x^{\kappa}+x^{-\kappa}}{2}\right)-\left(\frac{y^{\kappa}+y^{-\kappa}}{2}\right)+\sqrt{\left(\frac{x^{\kappa}+x^{-\kappa}}{2}-\frac{y^{\kappa}+y^{-\kappa}}{2}\right)^{2}-1}\right]^{\frac{1}{\kappa}} \tag{25}
\end{align*}
$$

where $\left(\frac{x^{\kappa}+x^{-\kappa}}{2}\right)-\left(\frac{y^{\kappa}+y^{-\kappa}}{2}\right) \geq 1$.
Note that $\lim _{\kappa \rightarrow 0} x \odot_{\kappa} y=\infty$, consequently there is no corresponding operation in the standard case of $\kappa=0$. However unless $\kappa=0$ this new product satisfies

$$
\begin{align*}
x \odot_{\kappa} y & =y \underset{\kappa}{\odot} x, & \text { comutativity }  \tag{26}\\
\left(x \odot_{\kappa} y\right) \underset{\kappa}{\odot} z & =x \underset{\kappa}{\odot}\left(y \odot_{\kappa} z\right) . & \text { associativity } \tag{27}
\end{align*}
$$

There exists no unit element within a real number. Therefore real numbers and this product consist a semigroup!
Note also that $x \odot_{\kappa} x \neq 1$ because $u_{\{\kappa\}}^{-1}(0)$ does not exist by the definition Eq. (20). However we see that the following identity holds.

$$
\begin{equation*}
x \odot_{\kappa} y{\underset{\kappa}{\kappa}} x=y, \quad(\kappa \neq 0) . \tag{28}
\end{equation*}
$$

Using the new $\kappa$-product, the associated $\kappa$-factorial can be introduced as

$$
\begin{align*}
n!^{\kappa} & \equiv 1 \odot_{\kappa}^{2} \underset{\kappa}{\odot} \cdots \odot_{\kappa} n \\
& =\left[\sum_{k=1}^{n}\left(\frac{k^{\kappa}+k^{-\kappa}}{2}\right)+\sqrt{\left\{\sum_{k=1}^{n}\left(\frac{k^{\kappa}+k^{-\kappa}}{2}\right)\right\}^{2}-1}\right]^{\frac{1}{\kappa}} . \tag{29}
\end{align*}
$$

Similar to Eq. (10), the $\kappa$-Stirling approximation can be obtained as

$$
\begin{align*}
u_{\{\kappa\}}\left(n!^{\kappa}\right) & =\sum_{k=1}^{n} u_{\{\kappa\}}(k) \approx \int_{0}^{n} d x u_{\{\kappa\}}(x) \\
& =\frac{n^{1+\kappa}}{2(1+\kappa)}+\frac{n^{1-\kappa}}{2(1-\kappa)} . \tag{30}
\end{align*}
$$

Also the corresponding $\kappa$-multinominal coefficient can be defined by

$$
\left[\begin{array}{c}
n  \tag{31}\\
n_{1} \cdots n_{k}
\end{array}\right]^{\kappa} \equiv n!^{\kappa}{\underset{\kappa}{\kappa}}\left(n_{1}!^{\kappa}{\left.\underset{\kappa}{\odot} \cdots \odot_{\kappa} n_{k}!^{\kappa}\right) .}\right.
$$

Applying the above Stirling approximation to Eq. (31) we obtain

$$
u_{\{\kappa\}}\left[\begin{array}{c}
n  \tag{32}\\
n_{1} \cdots n_{k}
\end{array}\right]^{\kappa} \approx \frac{n^{1+\kappa}}{2(1+\kappa)}\left\{1-\sum_{i=1}^{k}\left(\frac{n_{i}}{n}\right)^{1+\kappa}\right\}-\frac{n^{1-\kappa}}{2(1-\kappa)}\left\{\sum_{i=1}^{k}\left(\frac{n_{i}}{n}\right)^{1-\kappa}-1\right\} .
$$

This is the complemental relation to Eq. (15), and by combining Eqs (15) and (32) we have

$$
\ln _{\{\kappa\}}\left[\begin{array}{c}
n  \tag{33}\\
n_{1} \cdots n_{k}
\end{array}\right]_{\kappa} \pm \frac{1}{\kappa} u_{\{\kappa\}}\left[\begin{array}{c}
n \\
n_{1} \cdots n_{k}
\end{array}\right]^{\kappa} \approx \pm \frac{n^{1 \pm \kappa}}{\kappa(1 \pm \kappa)}\left\{1-\sum_{i=1}^{k}\left(\frac{n_{i}}{n}\right)^{1 \pm \kappa}\right\}
$$

We thus obtain the final result

$$
\begin{align*}
& \left(\frac{1-\kappa}{2 n^{1-\kappa}}\right)\left(\ln _{\{\kappa\}}\left[\begin{array}{c}
n \\
n_{1} \cdots n_{k}
\end{array}\right]_{\kappa}-\frac{1}{\kappa} u_{\{\kappa\}}\left[\begin{array}{c}
n \\
n_{1} \cdots n_{k}
\end{array}\right]^{\kappa}\right) \\
& +\left(\frac{1+\kappa}{2 n^{1+\kappa}}\right)\left(\ln _{\{\kappa\}}\left[\begin{array}{c}
n \\
n_{1} \cdots n_{k}
\end{array}\right]_{\kappa}+\frac{1}{\kappa} u_{\{\kappa\}}\left[\begin{array}{c}
n \\
n_{1} \cdots n_{k}
\end{array}\right]^{\kappa}\right) \\
& =\frac{1}{2 \kappa}\left\{1-\sum_{i=1}^{k}\left(\frac{n_{i}}{n}\right)^{1+\kappa}\right\}+\frac{1}{2 \kappa}\left\{\sum_{i=1}^{k}\left(\frac{n_{i}}{n}\right)^{1-\kappa}-1\right\}=S_{\kappa}\left(\frac{n_{1}}{n}, \ldots, \frac{n_{k}}{n}\right) . \tag{34}
\end{align*}
$$

Note that since

$$
\lim _{\kappa \rightarrow 0} \frac{1}{\kappa} u_{\{\kappa\}}\left[\begin{array}{c}
n  \tag{35}\\
n_{1} \cdots n_{k}
\end{array}\right]^{\kappa}=0
$$

as shown in the Appendix, Eq. (34) reduces to the standard case Eq. (2) in the limit of $\kappa \rightarrow 0$.

## IV. CONCLUSION

We have generalized Stirling approximation of the factorials and multinominal coefficients based on the $\kappa$-deformed function introduced by Kaniadakis, which is different oneparameter generalization from the $q$-deformed functions by Tsallis. In order to relate the $\kappa$-generalized multinominal coefficients to the $\kappa$-entropy, we showed the naive approach, which is similar to that [3] for the $q$-generalization, failed. In order to overcome this difficulty, we have introduced a new kind of the $\kappa$-product operations, which never exist in the standard case of $\kappa=0$, and have obtained the relation between the $\kappa$-generalized multinominal coefficients and the $\kappa$-entropy.

The final result Eq. (34) clearly states that the maximizing $\kappa$-entropy is equivalent to the maximizing the l.h.s. of Eq. (34) as same as in the standard case of Eq. (2). A next step in a future work is thus to clarify what microscopic states are described by the both $\kappa$-multinominal coefficients Eqs. (12) and (31).

## V. APPENDIX

We here show the proof of Eq. (35).

$$
\frac{1}{\kappa} u_{\{\kappa\}}\left[\begin{array}{c}
n  \tag{36}\\
n_{1} \cdots n_{k}
\end{array}\right]^{\kappa}=\frac{1}{\kappa}\left(\sum_{\ell=1}^{n} u_{\{\kappa\}}(\ell)-\sum_{i=1}^{k} \sum_{j=1}^{n_{i}} u_{\{\kappa\}}(j)\right),
$$

In the limit of $\kappa \rightarrow 0$ the numerator reduces to $n-\sum_{i=1}^{k} n_{i}$ since $\lim _{\kappa \rightarrow 0} u_{\{\kappa\}}=1$. Consequently both the denominator $\kappa$ and the numerator become null. Then applying l'Hopital's rule and using the relation

$$
\begin{equation*}
\frac{d}{d \kappa} u_{\{\kappa\}}(x)=\ln x\left(\frac{x^{\kappa}-x^{-\kappa}}{2}\right), \tag{37}
\end{equation*}
$$

we obtain Eq. (35).
