#### Abstract

W e propose two schem es to establish entanglem ent betw een two mesoscopic quantum system s through a third mesoscopic quantum system. The rst schem e entangles two nano-m echan ical oscillators in a non-G aussian entangled state through a C ooper pair box. E ntanglem ent detection of the nanom echan ical oscillators is equivalent to a teleportation experim ent in a $m$ esoscopic setting. The second schem e can entangle tw o C ooper pair box qubits through a nano-m echan ical oscillator in a them al state $w$ ithout using $m$ easurem ents in the presence of arbitrarily strong decoherence.

PACS num bers:

Probing quantum superpositions and entanglem ent w th m esoscopic $m$ echanical system $s$ has recently devel-
 icin tions are the interferom etry of $m$ esoscopic free particles ( $m$ olecules) $\left[\begin{array}{ll}{[1]}\end{array}\right]$ and the entangling of $m$ esoscopic atom ic ensembles [-lil. Proposals for the generation of entanglem ent betw een Bose $E$ instein condensates [ $[\underline{3}]$ and CO herence betw een states of $m$ esoscopic atom ic ensem bles have been $m$ ade $\left[\begin{array}{ll}{[1]}\end{array}\right]$. Som e early proposals involving harm onically bound m esoscopic system s w ere based on optom echanicale ects where schem es for observing coherent superpositions of states of the $m$ ovable $m$ irror tanglem ent betw een two such $m$ irrors [ $[6]$ w ere proposed. Soon, how ever, a canonical system of a C ooper-pair box coupled to a m esoscopic cantilever was introduced $\left.\bar{\eta}_{1} 1\right]$. It o ered an optics-firee, fully nano-technological alternative, $w$ th Sw itchable couplings for such schem es. A ccordingly, a schem e to observe coherent supenpositions betw een states of a m esoscopic cantilever, as well as its entanglem ent w ith a C ooper pair box was proposed [1] R ecently, interferom etric proposals to probe supenpositions of states of $m$ ovable $m$ irrors have also been proposed [ill $]$. Very recently, a proposal to entangle tw o well separated nano-electrom echanical oscillators through a harm onic chain has also been $m$ ade $\left[\frac{10}{[1]}\right.$. A host of other quantum e ects are expected to be seen in m esoscopic m echanical system $s[10,11,12,13$ quantum computation [1]. These theoretical proposals are fuelled by the rapid technological progress in the fabrication of nano-m echanicalsystem $s$ and experim ents approaching the quantum regim e [1G, [1] $]$.

The Ham iltonian which generates entanglem ent betw een a C ooper pair box and a cantilever in Ref. [̄] $\overline{1}]$ of fersm any $m$ ore exciting entangling possibilities even $w$ ith $m$ in $\dot{m}$ aladditions to the num ber of system $s$, such as just one extra C ooper pairbox or just one extra cantilever. In this letterwe show that w ith the abovem in im aladdition, one can entangle tw $\circ \mathrm{m}$ esoscopic system s of the sam e di$m$ ension: tw o discrete variable system $s$ (tw o C ooper pair
boxes) or two continuous variable system $s$ (two nano$m$ echanical cantilevers). O ne can also verify their entanglem ent with an entanglem ent witness or teleportation w ith higher than classically achievable delity. An interesting feature of the entangling of the cantilevers is that they are placed in a non-G aussian continuous variable entangled state as a result of our schem e. T ill date, only G aussian entangled states have been used in continuous variable im plem entations of quantum inform ation processing [2d], and the schem e we suggest $m$ ight enable one to realize a non-G aussian entangled state. T he schem e we suggest for detection of the non-G aussian entanglem ent is equivalent to possibly the sim plest realization of a quantum teleportation experim ent $w$ ith entangled nano-m echanical cantilevers. P ositive features of the entangling schem e for the C ooper pair boxes are its applicability in entangling non-neighboring (not directly interacting) boxes in an array and its robustness to the therm al nature as well as decoherence of the states of the $m$ ediating cantilever. M ost im portantly, our schem es seek to extend the dom ain ofquantum behaviorby entan$g l i n g$ tw $o m$ esoscopic system $s$ through a third $m$ esoscopic system.

Entangling two nano-cantilevers: A Cooper pair box (CPB) is an exam ple of a qubit with states j0i and jli representing $n$ or $n+1$ C ooper pairs in the box $\left.\overline{1}_{1}, 2_{2}^{1} \overline{1}_{1}\right]$. It can be $m$ ade to evolve under $a \mathrm{H}$ am iltonian $\frac{\mathrm{E}_{J}}{2-}$ x $\mathrm{b} y$ the application of an appropriate voltage pulse $\left[\begin{array}{ll}{[1, ~} \\ 2 & 21 \\ 2\end{array}\right]$ where $x$ is the Pauli-X operator and the param eter $E_{J}$ is called the Josephson coupling. This gives rise to coherent oscillations betw een the j0i and $71 i$ states as observed in Ref. [2] $\overline{1}_{1}^{1}$. A nano-m echanical cantilever ( $\mathbb{N} C$ ), on the other hand is a sim ple exam ple of a quantum harm onic oscillator. $W$ e now proceed to the proposalfor entangling two cantilevers based on their interaction $w$ ith a single CPB. The setup is shown in F ig ${ }_{1}^{1 / 1}$. The H am iltonian required for the schem $e$ is given by
$H=2 E_{C}{ }_{z}+h!!_{m} a^{y} a+h!_{m} b^{y} b+f\left(a+a^{y}\right)+\left(b+b^{y}\right) g_{z} ;$
where the param eter $\mathrm{E}_{\mathrm{c}}$ is called the charging en-

FIG. 1: The gure show s a schem atic diagram of the setup for entangling two cantilevers, denoted as cantilever 1 and cantilever 2 respectively, through a C ooper pair box denoted as CPB. For the entangling, m easurem ents are only needed to be perform ed on the CPB, which is done with the help of the single electron transistor SET CPB. For veri cation of the entanglem ent of cantilevers 1 and 2 by a m esoscopic teleportation, $m$ easurem ents need to be perform ed on them through SET 1 and SET 2 respectively.
ergy of the Cooper pair box, $z$ is the Pauli-Z operator for the CPB, operators $a ; a^{y}$ and $b ; b^{y}$ are the creation/annihilation operators for two oscillators and is a coupling strength. W e assum e that the NCs are prepared in itially in their ground state (this is quite realistic for the G H z oscillators available now [19] by cooling, as suggested in Ref. $\left.(\overline{1}]_{-}^{\prime}\right)$ ). A ccordingly, we start $w$ th the cantilevers in the in itial state $j 0 i_{a}-j i_{b}$, where subscripts $a$ and $b$ denote the two cantilevers, and the CPB in the state $\bar{p}_{\overline{2}}^{1}(j 0 i+j 1 i)$ ( T his state can be prepared by using a voltage pulse to accom plish $a=2$ rotation about $x$-axis through $\frac{E_{J}}{2} \times$ followed by local phase adjustm ents). The evolution that takes place in a tim e $T==!\mathrm{m}$ is

$$
\begin{align*}
& P_{\overline{2}}^{1} \quad(j 0 i+j i) j 0 i_{a} j 0 i_{b}! \\
& P_{\overline{2}}^{1} \quad\left(e^{i \frac{2 E_{c} T}{h}} j 0 i j 2 i_{a} j 2 i_{b}\right. \tag{2}
\end{align*}
$$

where $==\mathrm{h}!_{\mathrm{m}}$ is a dim ensionless coupling and j 4 i are coherent states. For sim plicity, we w ill assum e that $\frac{2 E_{c} T}{h}$ is an integralm ultiple of 2 . We now measure the CPB in the basis j $i=P^{1} \frac{\overline{2}}{(j 0 i} \quad$ jli) to obtain the state

$$
\begin{align*}
j() i_{a b}= & \frac{1}{P^{2}}\left(\begin{array}{lll}
2 & 2 & i_{a} \\
j & 2 & i_{b} \\
& p^{2} i_{a} & 2 i_{b}
\end{array}\right) ;
\end{align*}
$$

where the upper and lower signs stand for the $j+i$ and $j$ i outcom es respectively. If 1 , as will happen, for exam ple, if one takes the param eters of $R$ ef. $\left[\begin{array}{l}1 \\ 1\end{array}\right]$, then $e^{16^{2}} O\left(10{ }^{7}\right)$ and both states $j() i_{a b}$ have nearly one ebit of entanglem ent and each outcom e has a proba-
bility of nearly $1=2$ to occur. $j$ ( ) $i_{a b}$ are a class ofnon$G$ aussian continuous variable entangled states known as entangled coherent states, proposed originally in the optical context [2]. It is trivial to check that the schem e also works if the cantilevers started in coherent states of non-zero am plitude.

Verifying the entanglem ent of the cantilevers by teleportation: An interesting question now is how to verify the entanglem ent of the states $j$ ( ) $i_{a b}$. The non-local character can be ascertained in principle from Bells inequality experim ents $[2 \overline{6}]$. H ow ever, these involve $m$ easurem ents in a highly non-classical (Schroedinger C atlike) basis [2] $[$ ], and could be rather di cult for a N C. Foran NC, position/m om entum $m$ easurem ents seem natural. Unfortunately, from joint uncertainties in position and $m$ om entum of the twoncs, the entangled nature of the state $j() i_{a b}$ cannot be inferred. W e will thus use quantum teleportation through $j() i_{a b}$ to dem onstrate its entangled nature. N ote that the possibility of teleportation of Schrodinger $C$ at states of a third oscillator through the entangled coherent state of two oscillators has already been pointed out by van Enk and Hirota [ $\left.\left.{ }_{2}^{2}\right]_{1}\right]$ in the quantum optical context. H ow ever, for NC , preparing a third N C in a highly non-classical state such as a Schrodinger cat is challenging, $m$ aking it directly interact w th one of the entangled NCs is di cult and m oreover, we do not want to increase the com plexity of the system by adding an extra NC.W ew ill thus concentrate on the teleportation of the state of a qubit through $j() i_{a b} w$ th better than classically achievable $(2=3)$ delity. This w ill prove the entangled nature of the state $j() i_{a b}$.

For the teleportation protocol, rst assum e that the NCs were prepared in $j(+) i_{\text {ab }}$ as a result of the $m$ easurem ent of the CPB in the $j$ i basis. The CPB is now, of course, disentangled from the state of the NCs. It is thus now prepared in the anbitrary state $\cos =2 j 0 i+e^{i} \sin =2 j 1 i$ which we want to teleport through $j(+) i_{a b}$. The CPB interacts $w$ th cantilever a for a time $T$ and the resulting evolution is:

$$
\begin{align*}
& \left(\cos =2 j 0 i+e^{i} \sin =2 j 1 i\right) j(+) i_{a b}! \\
& { }^{\frac{1}{2}} \quad \text { (cos }=2 j 0 i j 0 i_{a} j 2 i_{b} \\
& +e^{i} \sin =2 \text { jlijA } i_{a} j 2 i_{b} \\
& +\cos =2 j 0 i j 4 \text { i } \quad i_{a} i_{b} \tag{4}
\end{align*}
$$

The position of the cantilever $a$ and the state of the CPB in the $j i$ basis are now $m$ easured. All the above corresponds to the Bell state $m$ easurem ent part of the teleportation procedure. As e ${ }^{8}{ }^{2} \ll 1$, there is a probability $\quad 1=2$ that the cantilever is projected to the state $j 0 i_{a}$. Let us, for the $m$ om ent, concentrate on this outcom e. Contingent on this outcom e, the state of
the CPB is projected to $j+i$ and $j i w i t h 1=2$ probability each, corresponding to which the state of cantilever $b$ goes to $\cos =2 j 2 \dot{j}^{2}+e^{i} \sin =2 \dot{2}$ iond $\cos =2 j 2$ í $e^{i} \sin =2$ 2 $\dot{i}$. Let us assum e the state to be $\cos =2 j 2 \dot{i}_{i}+e^{i} \sin =2 \mathcal{2}_{2} \dot{i}^{i}$ for the m om ent. In som e sense the above state of cantilever b already contains the teleported quantum inform ation from the originalstate of the CPB. H ow ever, it is di cult to verify this inform ation while it resides in the state of cantilever $b$. So we m ap it back from cantilever b to the CPB (which is now disentangled as a result of the previous $m$ easure$m$ ent) by preparing the CPB in the state $j+i$, allow ing for the evolution

$$
\begin{align*}
& P^{1}\left(\cos =2 j 0 i j 0 i_{0}+e^{i} \sin =2 \text { jlija } i_{0}\right. \tag{5}
\end{align*}
$$

and then $m$ easuring the position of cantilever $b$. $W$ ith a probability $1=2$ it is $j 0 i_{b}$, forwhich the CPB is pro jected to the state cos $=2 j 0 i+e^{i} \sin =2 j i$, thereby concluding a chain of operations leading to teleportation with unit delity. In the case when the outcome j ij0ia is obtained during the B ellm easurem ent procedure, a teleportation w ith unit delity can also be perform ed on obtaining $j 0 i_{b}$ in the $m$ apping back stage followed by the correction of a known phase factor. For the outcom es $j$ ij $4 i_{a}$ and $j$ ijf $i_{a}$ in the Bell state $m$ easurem ent, the CPB is prepared in states j0i and jli respectively, while for $j 4 i_{b}$ and $j 4 i_{b}$ in the $m$ apping back stage, it is prepared in states $j 0 i$ and $71 i$ respectively. This com pletes our teleportation protocol. T he delity of the procedure is thus unity w ith probability $1=4, \cos ^{2}=2 \mathrm{w}$ ith probability $(3=8) \cos ^{2}=2$ and $\sin ^{2}=2 \mathrm{w}$ ith probability $(3=8) \sin ^{2}=2$. A veraging over all possible in itial states one then gets an average delity of $3=4$, which is greater than the classical teleportation delity of $2=3$.

Let us clarify the sense in which the above is a bona de teleportation procedure despite the system $s$ being adjacent and the sam e CPB being reused. The CPB interacts $w$ th only cantilever a during the B ell state $m$ easurem ent procedure and hence this can be considered as a local action by a party holding cantilever $a$. The CPB is autom atically reset in the process as a fresh qubit not bearing any $m$ em ory of its initial state. In the $m$ apping back stage it can thus be regarded as a local device used by the party holding cantilever b for extraction of the state.

D ecoherence of the cantilever, if signi cant, will of course a ect both the generation of the state $j(+) i_{a b}$, as well as the teleportation. H ow ever, decoherence of a cantilever is in the coherent state basis and it will sim ply multiply the o diagonalterm j $2 i_{a} j 2 i_{b} h 2$ in h2 ib (and its conjugate) in $j(+) i_{a b}$ by a factor of the form $e \quad$ where e $\quad e^{8^{2}}=Q$ in which $Q$ is the quality factor of the cantilevers $\left[\overline{7}_{1}\right]$ (note that as physi-
cally expected, higher the quality factor, lower the decoherence). Sim ilarly, in evolutions given by Eq. ( $\overline{4} 1$

 by $e^{5=2}$ and $e^{=2}$ respectively. The net e ect of decoherence at the end of the teleportation will then be a reduction of delity corresponding to the $j$ ij0i $i_{a}$ outcom e ofthe Bellstate $m$ easurem ent to $\left(2+e{ }^{4}\right)=3$, while the delity corresponding to other outcom es w ill rem ain unchanged. Thus unless all coherence is destroyed by decoherence i.e., e ${ }^{4} \quad 0$, we have an average teleportation delity $2=3+e^{4}=12$, which is better than $2=3$. For example, for Q 1000 [1] (for 1[]$\left.\left._{1} 1\right]\right)$ and average teleportation delity is $0: 74$. In this paper we assum e that the CPB hardly decoheres over the ns tim e-scale of experim entsw ith a G H z N C [7,

Entangling two CPBs: The setting of our schem ef entangling two CPBs as depicted in Fig is tw o CPBs coupled to a single N C. The H am iltonian for this system, in the absence of the voltage pulse giving rise to $\frac{\mathrm{E}_{J}}{2} \mathrm{x}$, is well approxim ated (by straightforw ard extrapolation ofRef. [IT1]) as
${ }_{z}^{(i)}$ is a Pauli-Z operator of the ith C ooper pair box, $a ; a^{y}$ are the annihilation-creation operators of the nanocantilever. W e initially consider the NC to be starting in the coherent state $j i$ (we shall generalize later to a them alstate) and the C PB's to be initialized in the state $j 0 i_{1}-0 i_{2}$, where labels 1 and 2 stand for the tw o CPBs. At rst, the Ham iltonian $\frac{E_{J}}{2} \mathrm{x}$ is applied to each CPB to rotate their states from $j 0 i$ to $\frac{1}{2}(j 0 i+j 1 i)$. T hen evolution according to the Ham iltonian H kicks in and in a time $T==!m_{m}$ the evolution of the state can be calculated from Ref. [10 ${ }^{-1}$ to be

$$
\begin{align*}
& P_{\overline{2}}^{1}\left(j 0 i_{1}+j i_{1}\right) p_{\overline{2}}^{1}\left(j 0 i_{2}+j l i_{2}\right) j i! \\
& \left.\frac{1}{2} f e^{i\left(E_{C} T+\right.}(T ; ;)\right) j 0 i_{1} j 0 i_{2} j \quad 4 i \\
& +\left(j 0 i_{1} j i_{2}+j i_{1} j 0 i_{2}\right) j i \\
& \left.+e^{i\left(E_{C} T\right.} \quad(T ; i)\right) j i_{1} j i_{2} j+4 i g ; \tag{7}
\end{align*}
$$

where ( T ; ; ) $=2 \mathrm{Im}$ is a phase factor and $j \quad i, j \quad 4 i$ and $j+4 i$ are coherent states. The sign ip from ! in the above evolution occurs due to the oscillator evolution for half a tim e period. T he production of states of the above type has been noted earlier in the context of cavity-2 ED [22] and very recently in the context of $m$ easurem ent based quantum com putation [23]. In Ref.[23], it has been pointed out that for a large, a m easurem ent of the oscillator $\mathbb{N} C$ in our case) will project the two qubits (CPBs in our case) probabilistically to the m axim ally entangled state $j^{+} i_{12}=\frac{1}{2}\left(j 0 i_{1} \mathcal{H} i_{2}+j i_{1} j 0 i_{2}\right)$. Such an entangled
state can, of course, be veri ed through Bell's inequaltities by m easurem ents on the CPBs. H ow ever, here we want to go beyond this result and reduce the require$m$ ents necessary for observing entanglem ent betw een the CPBS. Suppose the cantilever is in a high tem perature therm al state so that position $m$ easurem ents of the cantilever would be ine cient due to therm alnoise. $W$ e thus ask the question as to whether we can observe any entanglem ent betw een the CPBSw ithout the extra com plexity ofm easurem ents on the $N C$. T he reduced density $m$ atrix of the two CPBs, when the states of the NC are traced out will, for large, be

$$
\begin{equation*}
12=\frac{1}{4}\left(j 00 i h 00 \dot{i}_{12}+j 1 i h 11 \dot{1}_{12}\right)+\frac{1}{2}+\quad{ }^{12}: \tag{8}
\end{equation*}
$$

In deriving the above we have taken the overlap of coherent states $h \quad j \quad 4 i, h \quad j \quad+4 i$ and $h+4 j \quad 4 i$ to be nearly zero. Note that when decoherence of the states of the cantilever is taken into account, as it occurs in the coherent state basis $\left[\bar{p}_{1}\right]$, we can, w thout loss of generality, replace $j i, j \quad 4 i$ and $j+4 i$ in Eq. $\bar{j}(\overline{1})$ by j ij i,j 4 ij 4 i and $j+4 i j+4 i$ where j $i, j \quad 4$ i and $j \quad+4$ i are three distinct environm entalstates $w$ th pairw isem utual overlap tending to zero in the lim it of strong decoherence. T hereby, for

1, the reduced density $m$ atrix of the tw o C P B s is una ected by decoherence and still given by 12 of Eq. ( $\overline{8} 1$ ). . A lso, note that 12 does not, in any way, depend on the in itial coherent state am plitude. Thus even if we were $\mathrm{k}^{\mathrm{k}}$ o start in a them al state of the cantilever given by
$d^{2} P() j$ ih $j$ the state of the two CPB qubits for large $w i l l$ be 12 foratime $T=\quad=!\mathrm{m}$.

Veri cation of the entanglem ent of the CPBs: 12 is an entangled state, but not one that violates a Bell's inequality. So we have to check the entanglem ent of the CPBs through an entanglem ent witness one has to $m$ easure the expectation value of the operator [24]

$$
\begin{equation*}
W=\frac{1}{4} f I \quad I+z \quad z \quad x \quad x \quad y \quad y g \tag{9}
\end{equation*}
$$

for the state of the CPB qubits. The expectation value of $W$ is positive for all separable states, so if it is found to be negative, then we can conclude that the CPBs are entangled. In fact, for the predicted state 12 at $T==!\mathrm{m}$, the expectation value of $W$ is $0: 25$. N ote that the operator $W$ is a locally decom posable w itness [2" 2in $_{1}^{1}$ ] which $m$ eans that it is $m$ easurable by $m$ easuring only localoperators in the sam e m anner as Bell's inequalities. Its 0 cally decom posable form is evident from Eq. $(\underline{\underline{1}})$. T hus no interactions betw een the C P B s are needed to verify their entanglem ent, and they can well.be beyond the range of each other's interactions. W e have thus proposed a way of entangling two CPBs through a cantilever in them al state in the presence of decoherence w thout using any

| SET1 | SET2 <br> CPB1 |
| :--- | :---: |
| CANTILEVER | CPB2 |

FIG. 2: The gure shows a schem atic diagram of the setup for entangling tw o C ooper pair boxes, denoted as CPB1 and CPB2 respectively, through a cantilever. For the entangling procedure, no m easurem ents are required. For veri cation of the entanglem ent through a witness, $m$ easurem ents need to be perform ed on CPB1 and CPB 2 through the single electron transistors SET 1 and SE T 2 respectively.
$m$ easurem ents. $T$ his is an usefulaltemative to entangling the C P B sby direct interaction, as it w illw ork even when the CPBs fall outside the range of each other's interaction. W e have also proposed a $m$ ethod to verify their entanglem ent through localm easurem ents on each of the CPBS. O fcourse, if the CPB sw ere allow ed to resonantly exchange energy $w$ th a $m$ ode of the cantilever in analogy w th R ef. $\left.[1]_{1}^{-}\right]$, then not only entanglem ent, but any quantum com putation would be possible in of low decoherence [17ㄱ﹎ㄴ. The presence of arbitrarily strong decoherence will, how ever, a ect such a m ethod. W hat we have shown is that even given the H am iltonian of Ref . [ipi], anbitrarily strong decoherence and them alstates, entanglem ent betw een the C P B s is still possible.

C onclusions: In this paper we have proposed a schem e to entangle two m esoscopic system $s$ of the sam e type through a third m esoscopic system. In this context we have also proposed a teleportation experim ent in the m esoscopic setting using continuous variable entangle$m$ ent for discrete variable teleportation.
