Abstract. The periodical dependencies in magnetic field of the asymmetry of the current-voltage curves of asymmetric aluminum loop are investigated experimentally at different temperatures below the transition into the superconducting state $T < T_c$. The obtained periodical dependency of the critical current on magnetic field allows to explain the quantum oscillations of the dc voltage as a consequence of the rectification of the external ac current and to calculate the persistent current at different values of magnetic flux inside the loop and temperatures.

Keywords: Mesoscopic superconductor loop, persistent current, quantum oscillations.

PACS: 74.78.Na, 74.78.-w

INTRODUCTION

The persistent current $I_p = sj_p = s2en_s v_s$ should flow along circumference of a superconductor loop l with thin section $s < \lambda_L^2$ at $\Phi \neq n\Phi_0$ since the state with zero velocity of superconducting pairs $v_s = 0$ is forbidden when the magnetic flux Φ inside l is not divisible by the flux quantum $\Phi_0 = h/2e$ [1]. Its equilibrium value and sign $\langle I_p \rangle = s2en_s \langle v_s \rangle \propto \langle n \rangle - \Phi/\Phi_0$ vary periodically with Φ [1]. The Little-Parks resistance oscillations $R_l(\Phi/\Phi_0)$ [2] observed in the loop [3] is experimental evidence of $I_p \neq 0$ at non-zero resistance $R_l > 0$. According to an analogy with the conventional circular current a dc potential difference $V(\Phi/\Phi_0) \propto I_p(\Phi/\Phi_0) \propto \langle n \rangle - \Phi/\Phi_0$ may be expected to be observed on segments of asymmetric superconductor loop at $R_l > 0$. Such quantum oscillations of the dc voltage were observed on segment of asymmetric aluminum loops [4,5] and much before on a double Josephson point contact [6]. The dc voltage $V(\Phi/\Phi_0)$ observed near the critical temperature T_c [4,6] can be induced by switching of the loop between superconducting states with different connectivity [7,8]. The quantum oscillations $V(\Phi/\Phi_0)$ induced at lower temperatures by an external ac current [5] may be interpreted as a result of the rectification because of asymmetry of the current-voltage curves sign and value of which are periodical function of Φ . The results of measurements of this periodical change of the asymmetry of the current-voltage curves with value of magnetic flux Φ

inside asymmetric aluminum loop at different temperatures are presented in this work.

EXPERIMENTAL DETAILS AND RESULTS

Microstructures consisting of asymmetric Al rings with semi-ring width $w_n = 200$ nm and $w_w = 400$ nm for the narrow and wide parts, respectively, see Fig.1,

were investigated. 4 μm diameter single asymmetric superconductor ring (ASR) and 20 ASR structures, see Fig.1, were fabricated by e-beam lithography and lift-off process of film $d = 45\text{-}50$ nm in thickness, thermally evaporated on oxidized Si substrates. For these structures, the sheet resistance was $0.23 \Omega/\square$ at 4.2 K, the resistance ratio $R(300\text{K})/R(4.2\text{K})=2.7$, and the critical temperature was $T_c = 1.24\text{-}1.27$ K.

Current -Voltage Curves

The structure as a whole jumps into the resistive state $R > 0$ (at a low temperature $T < 0.985T_c$) when the current density exceeds the critical value j_c in any of its segment and the irreversibility of the current-voltage curves is observed at $T < 0.99T_c$. The value of the external current I_{ext} corresponding to this jump to the state with $R > 0$ is measured as the critical current $|I_{\text{ext}|c}$ of the structure.

FIGURE 2. Quantum oscillations of the critical current $|I_{\text{ext}|c}(\Phi/\Phi_0)$ of system of 18 asymmetric Al loops with $w_{\text{con}} = 400 \text{ nm} < w_n + w_w$ measured in opposite directions $|I_{\text{ext}|c+}$, $|I_{\text{ext}|c-}$ at $T \approx 0.978T_c$. The quantum oscillations of the dc voltage $V(\Phi/\Phi_0)$ induced by the external ac current with the frequency $f = 40$ kHz and the amplitude $7 \mu\text{A}$ are shown also.

Periodical Dependence of $|I_{\text{ext}|c}(\Phi/\Phi_0)$

Our measurements have revealed the periodical magnetic dependencies $|I_{\text{ext}|c}(\Phi/\Phi_0)$ of both single rings and systems of rings with both $w_{\text{con}} < w_n + w_w$, see Fig.2, and $w_{\text{con}} \geq w_n + w_w$. These periodical dependencies may be explained as a consequence of superposition of the external I_{ext} and persistent $I_p(\Phi/\Phi_0)$ currents. The current density in the narrow j_n and wide j_w semi-rings is determined by both the I_{ext} and I_p currents: $j_n = I_{\text{ext}}/d(w_n + w_w) \pm I_p/dw_n$ and $j_w =$

$I_{\text{ext}}/d(w_n + w_w) \pm I_p/dw_w$ [5]. The summation “+” takes place when the direct I_{ext} and circular I_p currents have the same direction in the semi-rings, see Fig.1. The current density mounts the critical value j_c first of all in the narrow semi-rings at $|I_{\text{ext}|c} = d(w_n + w_w)(j_c - I_p/w_n)$, in the wide ones at $|I_{\text{ext}|c} = d(w_n + w_w)(j_c - I_p/w_w)$ or in the stripes connecting the rings at $|I_{\text{ext}|c} = dw_{\text{con}} j_c$ depending on the I_{ext} and I_p directions and the j_p/j_c and $w_{\text{con}}/(w_n + w_w)$ values.

Our results of the measurement of $|I_{\text{ext}|c}(\Phi/\Phi_0)$ are evidence of the periodical dependence not only value but also sign of $I_p(\Phi/\Phi_0)$ since the $|I_{\text{ext}|c}(\Phi/\Phi_0)$ value depends on the I_{ext} direction, $|I_{\text{ext}|c+} \neq |I_{\text{ext}|c-}$, i.e. the current-voltage curves are asymmetric, at some Φ/Φ_0 values, see Fig.2. For example $|I_{\text{ext}|c+}$ (at the right I_{ext} direction) has a minimum value at $\Phi/\Phi_0 \approx 0.2 \pm n$ whereas $|I_{\text{ext}|c-}$ (at the left I_{ext} direction) the minimum is observed at $\Phi/\Phi_0 \approx 0.8 \pm n$, see Fig.2. This means that the persistent current has the clockwise direction at $\Phi/\Phi_0 \approx 0.2 \pm n$ and the counter-clockwise one at $\Phi/\Phi_0 \approx 0.8 \pm n$ since the minimum of $|I_{\text{ext}|c}$ is observed when the I_{ext} and I_p have the same direction in the narrow semi-rings, see Fig.1. The experimental dependencies $|I_{\text{ext}|c+}(\Phi/\Phi_0)$, $|I_{\text{ext}|c-}(\Phi/\Phi_0)$ obtained in our work allow to explain the quantum oscillations of the dc voltage $V(\Phi/\Phi_0)$ as consequence of the rectification and to calculate the $I_p(\Phi/\Phi_0; T)$ dependencies at $T < T_c$.
