#### Abstract

W e study the super uid-insulator transitions ofbosons on the $K$ agom e lattice at incom $m$ ensurate lling factors $f=1=2$ and $2=3$ using a duality analysis. W e nd that at $f=1=2$ the bosons will alw ays be in a super uid phase and dem onstrate that the $T_{3}$ sym $m$ etry of the dual (dice) lattice, which results in dynam ic localization of vortices due to the A haronov-Bohm caging e ect, is at the heart of this phenom enon. In contrast, for $f=2=3$, we nd that the bosons exhibit a quantum phase transition between super uid and translational sym m etry broken $M$ ott insulating phases. $W$ e discuss the possible broken sym $m$ etries of the $M$ ott phase and elaborate the theory of such $a$ transition. Finally we m ap the boson system to a XXZ spin modelin a magnetic eld and discuss the properties of th is spin $m$ odel using the obtained results.

PACS num bers:

## I. INTRODUCTION

$T$ he super uid (SF) to $M$ ott insulators (M I) transitions of strongly correlated lattioe bosons system s, described by extended H ubbard m odels, in tw o spatial dim ensions have recently received a great deal of theoretical interest. O ne of the reasons for this renewed attention is the possibility of experim ental realization of such models using cold atom s trapped in optical lattiged ${ }^{\text {ditu }}$. H ow ever, such transitions are also of interest from a purely theoretical point of view, since they provide us w ith a test bed for exploring the recently developed theoretical paradigm ofnon-Landau-G inzburg-W ilson (LGW ) phase transitions ${ }^{3}$. In the particular context of lattice bosons in tw o spatial dim ensions, a general fram ew ork for such non-LG W transitions has, been developed and applied to the case of square lattica ${ }^{1_{1}^{1}}$. An application of these ideas for triangular lattioe has also been carried out5ㄴ.

Thetypicalparadigm ofnon-LGW transitionsthat has been proposed in the context of lattice bosons in $R$ efs. ' 1 ' and ' ings $f=p=q$ of bosons per unit cell of the underlying lattice ( $p$ and $q$ are integers), the theory of phase transition from the super uid to the $M$ ott insulator state is described in term $s$ of the vortioes which are non-local topological excitations of the super uid phase, living on the dual lattice ${ }^{\prime}$, ${ }^{\prime}$ I' $T$ hese vortices are not the order param eters of either super uid or $M$ ott insulating phases in the usual LGW sense. Thus the theory of the above $m$ entioned phase transitions are not described in term $s$ of the order param eters on either side of the transition which is in contrast w th the usual LGW paradigm of phase transitions. A lso, as explicitly dem onstrated in Ref. $\bar{A}_{1}^{1} 1$ although these vortiges are excitations of a featureless super uid phase, they exhibit a quantum order which depends on the lling fraction $f$. It is shown that the vortex elds describing the transition form multiplets transform ing under projective sym $m$ etry group (projec-
tive representations of the space group of the underlying lattioe). It is found that this property of the vortices naturally and necessarily predicts broken translational sym $m$ etry of the $M$ ott phase, where the vortioes condense. Since this translational sym $m$ etry breaking is dependent on the sym $m$ etry group of the underlying lattice, geom etry of the lattice naturally plays a key role in determ ining the com peting ordered states of the $M$ ott phase and in the theory ofquantum phase transition betw een the $M$ ott and the super uid phases.

In this work, we apply the theoretical fram ew ork developed in Refs. ${ }^{4} 4$ to bosons on $K$ agom e lattioe described by the extended ${ }^{-}$ose $H$ ubbard $H$ am iltonian

$$
\begin{align*}
& H_{\text {boson }}={\underset{X}{\text { hiji }}}_{\mathrm{X}}^{X} b_{i}^{y} b_{j}+h: c:+\frac{U}{2}{ }_{i}^{X} n_{i}\left(n_{i}\right. \\
& +V^{X}{ }_{n_{i j i}} n_{j} \quad{ }_{i} n_{i} \tag{1}
\end{align*}
$$

at boson llings $f=1=2$ and $2=3$. Here $t$ is the boson hopping am plitude betw een nearest neighbor sites, $U$ is the on-site interaction, $V$ denotes the strength of the nearest neighbor interaction betw een the bosons and
is the chem icalpotential.
$T$ he $m$ ain $m$ otivation of this study is tw ofold. First, since the geom etry of the underly ing lattice plays a sign ificant role in determ ining the nature of the M ott phase, we expect that such phases in $K$ agom e lattioe would be distinct from their square $e^{44}$ or triangular ${ }^{515}$ counterparts studied so far. In particular, the dual of the K agom e lattiøe is the dice lattice which is known to have $T_{3}$ sym $m$ etry $y^{818}$. It is well known that the particles in a $m$ agnetic eld on such lattioe experience a destructive $A$ haronov $-B$ ohm interference e ect at special values of the extemalm agnetic ux leading to dynam ic localization of the particles. Thisphenom enon is term ed as A haronov-B ohm caging in Ref.ig. In the problem at hand, the vortioes reside on the dual (dice) lattice and the boson lling $f$ acts as the ef-
fective $m$ agnetic $u x$ for these vortices. C onsequently, we nd that at lling $f=1=2$, the vortipes becom e 1 calized w ithin the A haronov-B ohm cage ${ }^{9} 9$ and can never condense. A s a result, the bosons alw ays have a featureless super uid ground state. Such localization of vortices and consequently the absence of a $M$ ott phase for bosons is a direct consequence of the geom etry of the $K$ agom $e$ (or it's dual dice) lattice and is distinctly di erent from expected and previously studied behaviors of bosons on square or triangu lar latticesi ${ }^{4} \sqrt{51}$ w hose dual lattices do not have $T_{3}$ sym m etry. In contrast, for $f=2=3$, we nd that there is a translationalsym $m$ etry broken $M$ ott phase and discuss the possible com peting ordered states in the M ott phase based on the vortex theory at a m ean- eld level. W e also address the question of quantum phase transition from such an ordered state to the super uid and write down an e ective vortex eld theory for describing such a transition.
$T$ he second $m$ otivation for undertaking such a study com es from the interest in physics of XXZ models with ferrom agnetic $J_{x}$ and antiferrom agnetic $J_{z}$ interaction in a longitudinalm agnetic eld $\mathrm{B}_{1}$

$$
\begin{aligned}
& B_{1} \quad S_{i}^{z} \\
& \text { i }
\end{aligned}
$$

$w$ here $J_{x}>0$ and $J_{z}>0$ are the strengths of transverse and longitudinal nearest neighbor interactions. Such spin $m$ odels on- $K$ agom e lattice have been widely studied num erically $y^{9}$ $m$ odel (in the presence of an additional transverse $m$ agnetic eld) has also been studied beforen ${ }_{1}^{n}$. A couple of qualitative points em erge from these studies. $F$ irst, in the absence of extemal eld $B_{1}$, such $m$ odels on $K$ agom $e$ lattioe do not exhibit $S_{z}$ ordering for any values of $J_{z}=J_{x}$. This absence of ordering is an unique property of the $K$ agom e lattioe and it has been conjectured that the ground state is quantum disordered $1^{111}$ Second, for $B_{1} \in 0$ and net m agnetizations $\mathrm{m}=\mathrm{h} S_{\mathrm{z}} \mathrm{i}=\sim=6$; $\sim=3$, the m odel exhibit a quantum phase transition betw een a featureless state $w$ ith $h S_{x} i \in 0$ to a translational sym $m$ etry broken ordered state with nite m. U sing a sim ple HolsteinP rim ako transform ation which $m$ aps the $H x x z$ (Eq. ${ }^{\prime}$, to hardcore Bose H ubbard m odel $\mathrm{H}_{1}$ (Eq. 'IL'), we show that it is possible to understand both of these features analytically at least at a qualitative level. The absence $S_{z}$ ordering for $B_{1}=0$ (which corresponds to average boson lling $f=1=2$ ) tums to be a natural consequence ofA haronov-B ohm caging phenom enon discussed earlier. Further, the results from the analysis of the B oson $m$ odel at $f=2=3$ can also be carried over to study the possible $S_{z}$ orderings of the spin $m$ odel at net $m$ agnetization $\sim=3$ which allow s us to $m$ ake contact $w$ ith recent num erical studies in Refs. 19
$T$ he organization of the paper is as follow s . In the next section, we m ap betw een the spin $m$ odel $H x x z$ to an boson $m$ odel and carry out a duality analysis of this boson
m odel. The dual Lagrangian so obtained is analyzed in Sec. follow ed by a discussion of the results in Sec. IV.I. Som e details of the calculations are presented in A ppendices'A':' Bi and

## II. DUALITY ANALYSIS

To analyze the spin $m$ odel $\mathrm{H}_{\mathrm{xxz}}$, our m ain strategy is to map it to a Boson model using the well-known Holstein $P$ rim ako transform ation

$$
\begin{equation*}
S_{i}^{+}=\left(S_{i}\right) \quad \text { b } S_{i}^{z} \quad b_{i}^{y} b_{i} \quad \frac{1}{2} \tag{3}
\end{equation*}
$$

Such a transform ation $m$ aps $\mathrm{H} x \mathrm{xz}$ to $\mathrm{H}_{1}$ given by

$$
\begin{align*}
& H_{1}=t^{X} \quad b_{i}^{y} b_{j}+h: c: \\
& \stackrel{\text { hiji }}{X} \\
& +V \quad\left(\begin{array}{lll}
n_{i} & f
\end{array}\right)\left(\begin{array}{ll}
n_{j} & f
\end{array}\right)  \tag{4}\\
& \text { hiji }
\end{align*}
$$

w ith the hardcore constraint $\mathrm{n}_{\mathrm{i}} \quad 1$ on each site. The param eters of the hardcore boson m odel $\mathrm{H}_{1}$ are related to those of Hxxz as

$$
\begin{equation*}
J_{\mathrm{x}}=2 \mathrm{t} ; \quad \mathrm{J}_{\mathrm{z}}=\mathrm{V} ; \quad \mathrm{B}_{1}=\mathrm{zV} \quad \mathrm{f} \quad \frac{1}{2} \tag{5}
\end{equation*}
$$

where $z$ is the boson coordination num ber. In the $M$ ott phases, the average boson density is locked to som e num ber and this will be $f$ in Eqs' $\overline{4}$ and $\overline{5} 1$ willconsider the super uid-insulator transitionsw ith the average boson density xed across the transition.

In what follow s, we would carry out a dually analysis of the hardcore boson $m$ odel. Such a duality analysis of the boson $m$ odel is $m$ ost easily_ done by im posing the hardcore constraint in $H_{1}$ (Eq. ('li') by a strong on-site Hubbard term potential to obtain $\mathrm{H}_{\text {boson }}$ (Eq. 'ill'). In the $\lim$ 辻 of strong $U$ the qualitative nature of the phases of the $m$ odel is expected to be the sam e as that of the hardcore $m$ odel. H ence for rest of the w ork, we shallconsider the boson $m$ odel $\mathrm{H}_{\text {boson. }}$. A lso, since we are going to carry out a duality analysis of this m odel, we shall not bother about precise relations betw een param eters of $\mathrm{H}_{1}$ and $H_{\text {boson }}$, but $m$ erely represent to be a chem icalpotentialwhich forces a xed lling fraction $f$ ofbosons as show $n$ in previous w ork ${ }^{4}$.
$T$ he dual representation of $H_{\text {boson }}$ can be obtained in the sam eway as in Refs. "In'. T he details of the duality transform ation are brie y sketched in A ppendix A'. The dual theory tums out to be a theory of (1) vortices, residing on the sites of the dual (dice) lattice show $n$ in $F$ ig. '111, coupled to a ctitiousm agnetic eld which depends on

F IG . 1: K agom e lattice (thin black line) and the unit cell of its dual dice (thick blue lines) lattice. The three inequivalent sites A, B and C of the dice lattioe are shown in the gure. The sides of the mom bus ABAC hajve length a and angles $\overline{\bar{p}} 3$. The basis vectors $u=(3 a=2 ; \overline{3} a=2)$ and $v=(3 a=2 ; \quad \overline{3} a=2)$ that span the dige lattice are show $n$ as arrowed lines. N ote that the A sides reside in the center of the hexagons of the $K$ agom e lattice while the $B$ and $C$ sites reside in the center of the triangles.
the boson lling $f$. The dualaction is given by

$$
\begin{align*}
& X^{b ;} \\
& +\quad r j b J^{\imath}+u j b J^{4}+:::: \tag{6}
\end{align*}
$$

where b are the vortex eld living on the site b of the dual (dice) lattioe, $A_{b}$ is the $U$ (1) dual gauge eld so that $\quad A_{b} P=n_{i}$ where $n_{i}$ is the physical boson density at site $i$, $\quad$ denotes sum over elem entary rhom bus of the dice lattioe; denotes lattice derivative along
$=x ; y ;$, and $f$ is the average boson density. Them agnetic eld seen by the vortioes is therefore the physical boson density. N ote that the vortex action $S_{d}$ is not selfdual to the boson action obtained from $\mathrm{H}_{\text {boson }}$. Therefore we can not, in general, obtain a m apping between the param eters of the two actions, except for, identifying $\quad A_{b}$ as the physicalboson density $y^{4,5} 5$. Therefore, in the rem ainder of the paper, we shall classify the phases of this action based on sym $m$ etry consideration and $\underline{w}$ thin the saddle point approxim ation as done in Ref.

The transition from a super uid ( $\mathrm{h} \mathrm{b}_{\mathrm{b}} \mathrm{i}=0$ ) to a M ott insulating phase in $S_{d}$ can be obtained by tuning the param eter $r$. For $r>0$, we are in the super uid phase. $N$ ote that the saddle point of the gauge elds $A_{b}$ in action corresponds to $\quad A_{b}=f$,so that the $m$ agnetic eld seen by the vortioes is pinned to the average boson lling $f$. Now as we approach the phase transition point $r=0$, the uctuations about this saddle point ( $h{ }_{\mathrm{b}} \mathrm{i}=0$,
$A_{b y}=f x$ ) increase and ultim ately destabilize the super uid phase in favor of a M ott phase w ith h bi 0 . $C$ learly, in the above soenario, the $m$ ost im portant uctuations of the vortex eld $b$ are the ones which has the low est energy. This prom pts us to detect the $m$ inim a of the vortex spectrum by analyzing the kinetic energy term of the vortioes
where the sum over is carried out over the six-fold (for A sites in Fig. '117) or three-fold (for B and C sites) coordinated sites surrounding the site b.

The analysis of $\mathrm{H}_{\mathrm{k} \text { inetic }}$ am ounts to solving the H ofstadter problem on the dice lattioe w hich has been carried out in $R$ ef. ${ }^{\prime}$ I'. W e shall brie $y$ sum $m$ arize the relevant part of that analysis. It is found that the secular equation obtained from $H_{k i n e t i c}$ for boson lling factor $f$ is given by ${ }^{81}$

$$
\begin{aligned}
& A(x ;)=B(x+h a)+C\left(\begin{array}{ll}
x & a
\end{array}{ }_{i}\right. \\
& +2 \cos h^{-} \quad\left(\begin{array}{ll}
x & a=4)+i_{\text {B }}\left(\begin{array}{ll}
x & a=2)
\end{array}\right)
\end{array}\right. \\
& +2 \cos \frac{-}{a}(x+a=4)+\quad c(x+a=2) \\
& B(x ;)=A\left(x h^{a}\right) \quad \text { i } \\
& +2 \cos \frac{-}{a}(x+a=4)+\quad A(x+a=2) \\
& \begin{aligned}
c(x ;)= & \text { A }^{\left(x h^{a}\right)} \quad i \\
& +2 \cos -\left(\begin{array}{ll}
x & a=4
\end{array}\right)+{ }^{i}
\end{aligned} \\
& +2 \cos \frac{-}{a}(x \quad a=4)+\quad A(x \quad a=2)(8)
\end{aligned}
$$

where $A, B$ and $C$ denote inequivalent sites of the dice lattice, $=2 \mathrm{f}=2=0$ for the boson $l l$ ing $f$, and is the dual ux through an elem entary mom bus of the lattioe. Here $=\left(\begin{array}{l}\text { А } ; ~ в ; ~ с) ~ i s ~ t h e ~\end{array}\right.$ vortex wavefunction which has been jp ritten as b
$(x ; y)=(x ; p) \exp (i n) w$ th $=3 k_{y} a=2$ and integer $n=2 y=(3 a), a$ is the lattioe spacing of the dice lattice, and is the energy in units of vortex fugacity l . For obtaining the solutions corresponding to $\in 0$, we elim inate for $B$ and $C$ from Eq. ${ }^{\prime}$ g to arrive at an onedim ensionalequation for $A(x=3 m a=2 ;) \quad$ A $(m ;)$

$$
\begin{align*}
& \frac{2}{2 \cos (=2)} \text { A }(m ;)=2 \cos (3 m+2)_{A}(m ;) \\
+ & 2 \cos \frac{3}{2}(m \quad 1=2)+\quad \text { A }(m \quad 1 ;) \\
+ & 2 \cos \frac{3}{2}(m+1=2)+\quad \text { A }(m+1 ;) \tag{9}
\end{align*}
$$

where we have used the fact that w ith our choice oforigin the A sites have $x=3 m a=2 w$ th integer $m$. For rational boson lling $f=p=q$, Eq. ${ }_{1}^{1-191}$ closes after translation by $q$ periods. However, for $q=3 q^{0}\left[q^{0} 2\right.$ integer], this periodicity is reduced to $q^{981}$.

A key feature of the wavefiunction that we would be using in the subsequent analysis is its transform ation property under all distinct space group operations
of the dice lattice. T herefore we collect all such transfor$m$ ations here for any general lling $f$. Such operations for the dice lattice, as seen from F ig. ' $\overline{1}_{1}^{\prime}$ ', inyolve translations $T_{u}$ and $T_{v}$ along vectors $u=(3 a=2 ; \quad \overline{3} a=2)$ and $v=(3 a=2 ; \quad 3 a=2)$, rotations $n=3$ for any integer $n$, and re ection $I_{x}$ about the $x$ axis. It is easy to check that these are the basic sym $m$ etry operations that $m$ ust leave the H am iltonian invariant and all other sym m etry operations can be generated by their appropriate com binations. Follow ing $m$ ethods outlined in Ref. $\overline{4} \overline{4}$, one nds the follow ing transform ation properties for the w avefunctions:

$$
\begin{aligned}
& T=u ; v:(x ; y)!\quad(x \quad x ; y \quad y)!x^{2}={ }^{p} \overline{3}(10) \\
& I_{x}:(x ; y)!\quad(x ; y)(11) \\
& R=3: ~ A(x ; y)!\quad \text { A } \quad\left[x+{ }^{p} \overline{3} y\right]=2 ;\left[y \quad P_{3} x\right]=2 \\
& !\left[\begin{array}{ll}
\left(y^{2}\right. & \left.\left.x^{2}\right)=4+{ }^{p} \overline{3} x y=2\right]
\end{array}\right. \\
& \text { в }(x ; y)!\quad \text { с } \quad\left[x+{ }^{p} \overline{3} y=2 ; \quad\left[y \quad{ }^{p} \overline{3} x\right]=2\right.
\end{aligned}
$$

$$
\begin{aligned}
& !\left[\left(\begin{array}{ll}
y^{2} & \left.\left.x^{2}\right)=4+{ }^{p}{ }^{3} x y=2\right]
\end{array}(12)\right.\right.
\end{aligned}
$$

where $(x ; y)$ are the coordinates of the dice lattice and $!=\exp \left(2 p \frac{i f}{3}\right)$, $H$ ere $m$ ay denote either ${ }_{A}(x=$ $3 m a=2 ; y=3$ na=2) or $B$ and $c$ at appropriate positions w ithin the unit cell. N ote that allother above m entioned sym $m$ etry operations can be generated by com bination of the operations listed in E qs. ind. in . For exam ple $I_{Y}=I_{x} R=I_{x} R^{3}=3$ and under this transfom ation
 Som e details of the algebra leading to Eqs. 1 sketched in A ppendix 'B1.

In what follow s, we are going to analyze the vortex theory for $f=1=2$ and $f=2=3$ which tums out to be the sim plest possible physically interesting fractions to analyze.

$$
\begin{gathered}
\text { III. PHASES FOR } f=1=2 \text { A ND } 2=3 \\
\text { A. } £=1 / 2
\end{gathered}
$$

The key di erence betw, enen square and triangular lattioes analyzed previously 4 ied in this work, com es out when we study the lling fraction $f=1=2$. From Eq. ${ }^{1}$, , we nd that for $f=1=2$,
$=$, so that the entire spectrum pollapses into three in nitely degenerate bands $=0 ; \overline{6}$. This situation is in shanp contrast to the square or the triangular lattioes w here the vortex spectrum for rationalboson lings $\mathrm{f}=\mathrm{p}=\mathrm{q}$ has a xed number of well de ned m inim a . It is possible that vortex-vortex interaction $m$ ay $m$ ake the degeneracy nite, but it is unlikely to be lifted com pletely by interaction? ${ }^{18}$. Therefore the vortex band has zero or at

FIG.2: A haronov-B ohm cage for a vortex on site 0 of the dide lattice. T he probability am plitude for the particle to be at 3 vanishes due to destructive interference betw een am plitudes from the paths $0!1!3$ and $0!2!$ 3. C onsequently the vortex can never propagate beyond the rim of the cage (black circles) and is dynam ically localized. A nalogous cages can be constructed for vortices on sites B and C - .
least extrem ely sm all bandw idth w ith no well-developed $m$ inim a at any w avevectorw hich im plies that the vortioes shall never condense ${ }^{12}$. C onsequently, we do not expect to have a $M$ ott insulating state at $f=1=2$, as seen in previous M onte C arlo studies $\mathrm{H}_{1}$ on K agom e lattioge ${ }^{19}$. C om paring the param eters of $\mathrm{H}_{1}$ and $\mathrm{H}_{\mathrm{xxz}}$ (Eq. ${ }^{-\bar{F}_{1}^{\prime}}$ ), we nd that such an absence ofM ott phase also im plies that X X Z m odels on K agom e lattice w ill have no $S_{z}$ ordering for $B_{1}=0$. This result $w a s$ also obtained by num erical study of the related transverse eld Ising $m$ odel on the K agom e lattioa ${ }^{111}$.

Physically, the collapse of the vortex spectrum into three degenerate bands can be tied to localization of the vortex w ithin the so-called A haronov-B ohm cages as explicitly dem onstrated in Refs. 'i, An exam ple of such a cage is show $n$ in $F$ ig. is localized at the central (white) A site can never propagate beyond the black sites which form the border of the cage. This can be understood in term $s$ of destructive A haronov $B$ ohm interference: $T$ he vortex has two paths 0 ! $1!3$ and $0!2!3$ to reach the rim site 3 from the starting site 0 . T he am plitudes from these paths destructively interfere for $f=1=2$ to cancel each other and hence the vortex can never propagate beyond the rim of the cage. Sim ilar cages can be constructed for vortioes w ith initial wavepacket at sites B and C ${ }^{8} \mathbf{B}_{1}^{8}$. $T$ his dynam ic localization of the vortex wavepackets in realspace, dem onstrated and term ed as A haronov-B ohm caging in Ref. ${ }_{l}^{1,1}$, naturally leads to spreading of the vortex wavepacket in $m$ om entum space. H ence the vortex spectrum has no well-de ned $m$ inim a at any $m$ om enta leading to the absence of vortex condensation.
$T$ he question naturally arises regarding the nature of the boson ground state at $\mathrm{f}=1=2$ (or equivalently ground state of $X X Z \mathrm{~m}$ odel at $B_{1}=0$ and $\left.J_{z} \quad J_{x}\right)$. $T$ he dualvortex theory studied here can only predict the
absence of vortex condensation due to dynam ic localization of the vortices leading to persistence of super uidity (or $S_{x}$ ordering for XXZ m odel) at all param eter values. $B$ eyond this, num ericalstudies are required to discem the precise nature of the state. P revious studies of the transverse Ising model, which is related to the XXZ m odel, in Ref. 'III' have con jectured this state to be a spin liquid state. H ow ever, the M onte C arlo studies of the X X Z $m$ odela did not nd any sign of spin liquid state.

$$
\text { B. } \quad £=2 / 3
$$

In contrast to $\mathrm{f}=1=2$, the physics for $\mathrm{f}=2=3$ (or $\mathrm{f}=1=3$ ) tums out to be quite di erent. In this case, we do not have any dynam ic localization e ect and the vortex spectrum has well de ned minim a. N ote that for $\mathrm{f}=2=3, \mathrm{Eq}$.' ${ }^{\prime}$ closes after one period and the m agnetic B rillouin zone becom es identical to the dice lattice B ril-
 adm its a sim ple analytical solution

$$
\begin{align*}
& =\left(6 \quad 2 \cos (2)+4 \cos () \cos _{\mathrm{f}}(\mathrm{k})\right)^{1=2} \\
\mathrm{~A}(\mathrm{x} ; \mathrm{y}) & =\exp \left(\mathrm{im} 3 \mathrm{k}_{\mathrm{x}} a=2+\mathrm{n}\right) \tag{13}
\end{align*}
$$

where we have $2(0 ;)$ and $k_{x} 2(0 ; 4=3)$, and $k_{m}=$ $3 \mathrm{k}_{\mathrm{x}} \mathrm{a}=2$. The spectrum has two m inim a in the m agnetic B rillouin zone at $\left(k_{x} a ;\right)=(0 ;=3)$ and $(2=3 ; 2=3)$. $T$ he eigenfunctions $=\left({ }_{A} ; ~ \mathrm{~B} ; ~ \mathrm{C}\right)$, corresponding to
 They are

$$
\begin{align*}
1 & =\exp (i \mathrm{n}=3)(\mathrm{c} ; \mathrm{c} ; 0) \\
2 & =\exp \frac{2 \text { in }}{3}+i \mathrm{~m} \quad(c ; 0 ; \quad c) \tag{14}
\end{align*}
$$

where c is a nom alization constant. T hus the low energy properties of the vortex system can then be characterized in term sof the eld :

$$
\begin{equation*}
=1(x)^{\prime}{ }_{1}(x ; t)+2(x)^{\prime}{ }_{2}(x ; t) \tag{15}
\end{equation*}
$$

where ' ${ }_{1(2)}$ are elds representing low energy uctuations about the minim a ${ }_{1 \text { (2) }}$. As shown in Ref. $\overline{4} 4$, the transition from the super uid to the M ott phase of the bosons can be understood by constructing a low energy e ective action in term s of the' elds.

To obtain the necessary low energy Landau-G inzburg theory for the vortioes, we rst consider transform ation of the vortex elds' under the symm etries of the dice lattice. U sing Eqs. 1

$$
\begin{aligned}
& \mathrm{T}_{\mathrm{u}}:{ }^{\prime}{ }_{1}!{ }^{\prime}{ }_{1} \exp (\mathrm{i}=3) \quad{ }_{2} \text { ! }{ }^{\prime}{ }_{2} \exp (i=3) \\

\end{align*}
$$

Som e details of the algebra leading to Eq. $\cdot^{-1}{ }^{-1}$ ف is given in App. 'C.'. It is also instructive to w rite the two elds ' ${ }_{1}$ and ' 2 astwo com ponents of a spinor eld $=\left(\boldsymbol{r}_{1} ;^{\prime}{ }_{2}\right)$. $T$ he transform ation properties of can then be written as

$$
\begin{gather*}
\mathrm{T}_{\mathrm{u}}: \quad!\quad \exp \left(\mathrm{i}_{\mathrm{z}}=3\right) \\
\mathrm{T}_{\mathrm{v}}: \quad!\quad \exp \left(\mathrm{i}_{\mathrm{z}}=3\right) \\
\mathrm{I}_{\mathrm{x}}: \quad! \\
\mathrm{I}_{\mathrm{y}}: \quad!\quad \mathrm{x} \\
\mathrm{R}_{2}=3: \quad! \\
\mathrm{R}=3: \quad!\quad \mathrm{x} \tag{17}
\end{gather*}
$$

where $x ; y$; are the usual Pauli $m$ atrioes. N ote that $R_{2}=3$ plays the role of identity here where $R=3 \mathrm{~m}$ ixes the two com ponents of the spinor eld.

The sim plest Landau-G inzburg theory for the vortex elds which respects all the sym $m$ etries is

$$
\begin{align*}
& \mathrm{L}_{\mathrm{v}}=\mathrm{L}_{\mathrm{X}}^{(2)}{ }_{\mathrm{h}} \mathrm{~L}_{\mathrm{v}}^{(4)}+\mathrm{L}_{\mathrm{v}}^{(6)}  \tag{18}\\
& L_{v}^{(2)}={ }^{X} \quad j(i d \quad \text { eA })^{\prime} \quad j^{2}+r j j^{2^{i}}  \tag{19}\\
& =1 ; 2
\end{align*}
$$

$$
\begin{align*}
& \text { h i }  \tag{20}\\
& \mathrm{L}_{\mathrm{v}}{ }^{(6)}=\mathrm{w}\left(\mathrm{r}_{1}^{\prime}{ }_{2}\right)^{3}+\mathrm{h}: \mathrm{C}: \tag{21}
\end{align*}
$$

T he above lagrangian density can also be w ritten in term $s$ of the eldds. In particular the sixth order term becom es $L_{\mathrm{v}}^{6} \mathrm{~W} \quad \mathrm{a}=(\mathrm{a})^{3}$. This tums out to be the low est-order term which does not comm ute with $z$ and breaks the $U$ (1) sym $m$ etry associated $w$ th the relative phase of the bosons. A simple power counting shows that $L_{v}^{(6)}$ ism arginalat tree level. Unfortunately, the relevance/irrelevance of such a term beyond the tree level, which is of crucial im portance for the issue of decon ne$m$ ent at the quantum critical point, is not easy to deter$m$ ine in the present context for two reasons. First, the standard and large $N$ expansions does not yield reliable results for $2+1 \mathrm{D}$ eld theories, at least for $\mathrm{N}=2 \mathrm{which}$ is the case of present interest ${ }^{13}$. Second, while it is know $n$ from num erical studies that such a cubic anisotropy term is relevant for the single vortex species case (for X Y transitions in $2+1$ D), the situation rem ains far less from clear for the two vortex cas ${ }^{14} 4$. We have not been able to determ ine the relevance/irrelevance of this term in the present work.

If it so tums out that $\mathrm{L}_{\mathrm{v}}{ }^{(6)}$ is irrelevant, the situation here w illle identical to that ofbosons on square lattioe at $f=1=2$. The relative phase of the vortioes w ould em erge as a gapless low energy m ode at the critical point. T he quantum criticalpoint would be decon fed and shallbe accom panied by boson fractionalization ${ }^{\prime 4}$. On the other hand, if $\mathrm{L}_{\mathrm{v}}{ }^{(6)}$ is relevant, the relative phase degree of the bosons w ill alw ays rem ain gapped and there will be no decon nem ent at the quantum critical point. H ere there are tw o possibilities depending on the sign of $u$ and $v$. If

FIG.3: M ean- eld vortex state for $v>0 \mathrm{w}$ ith ${ }^{\prime}{ }_{1} 0$. The arrow s denote the phase of the vortex w avefinctions at the sites of the dual lattice. $N$ ote that all the sites of the $K$ agom $e$ lattice see the sam e vortex environm ent and are therefore equivalent. H ence we do not expect a density wave at the m ean- eld level.

FIG. 4: M ean- eld vortex state for $v<0$ with $\dot{J}_{1}$ J̈ $_{2} j=1$ and relative $=3$. The notations are sam e as in $F$ ig. The $m$ agnitudes of the vortex $w$ avefunctions are listed on the left, and $A, B$ and $C$ refers to corresponding inequivalent sites of the dual (dice) lattice where the vortices reside. H ere there are six inequivalent sites for the K agom e lattice which are listed in F ig. ${ }^{1}$.6.
u;v < 0 and w $>0$, the transition $m$ ay becom e weakly rst order whereas for $u>0$, it rem ains second order (but w thout any decon nem ent). The distinction betw een these scenarios can be made by looking at the order of the transition and the critical exponents in case the transition tums out to be second orderi.
$T$ he vortices condense for $r<0$ signifying the onset of the M ott state and now we list the possible M ott phases. O ur strategy in doing so would to be list the sites on the K agom e lattice which sees identical vortex environm ents (w thin $m$ ean- eld) and then obtain the possible ground states based on this classi cation for a xed boson lling $\mathrm{f}=2=3$. W e would like to stress that these results are obtained $w$ ithin $m$ ean- eld theory w ithout taking into account quantum uctuations.

FIG.5: M ean- eld vortex state for $v<0$ with $\mathrm{J}_{1} \mathrm{Ji}_{2} j=1$ and relative $=2=3$. This state also has six inequivalent sites. N otations are sam e as in F ig. ${ }^{4} \mathrm{~L}$.
$F$ irst let us consider the case $v>0$. Here only one of the vortex elds condense and consequently the $M$ ott state breaks the sym $m$ etry betw een $B$ and $C$ sites of the dual (dice) lattice. A plot of the $m$ ean- eld vortex wavefunction for $h^{\prime}{ }_{1}$ i $\in 0$ is show $n$ in $F$ ig. ${ }^{\prime}$ the arrow s denote the phase of the vortex w avefunction at the sites of the dual lattice while the am plitude of the wavefinctions are listed in the gures. $W$ e nd that for th is state all the sites of the K agom e lattioe see identical vortex environm ent and consequently, w ithin m ean- eld theory, we do not expect density-w ave ordering for the bosons. H ow ever, the up and down triangles have di erent vortex environm ents and one would therefore expect increased e ective kinetic energy of the bosons around either the up or down triangles. C onsequently one expects an equal supenposition state of bosons in which there is equal am plitude of the bosons in the sites around the up (down) trianglesín .

For v < 0, both the vortex elds have non-zero am plitude $i x: \jmath_{1} j=\dot{J}_{2} j \in 0$, and the ground state does not distinguish betw een the $B$ and the $C$ sites of the dige lattice. The relative phase betw een the vortex elds is xed by $\mathrm{L}_{\mathrm{v}}{ }^{(6)}$ :

$$
\begin{align*}
\text { relative } & =2 \mathrm{p}=3 \text { for } \mathrm{w}<0 \\
& =(2 \mathrm{p}+1)=3 \text { for } \mathrm{w}>0 \tag{22}
\end{align*}
$$

for integer $p$. The plot of the vortex $m$ ean- eld wavefunctions are show in $F$ igs. $\overline{1}$, for $w>0$ and $F$ ig. if for $\mathrm{w}<0$. The corresponding inequivalent sites, for $\mathrm{w}>0$, are charted in Fig. $\overline{1}_{1 .}$. W e nd that there are six inequivalent sites (de ned as those seeing a di erent vortex environm ent) in the $K$ agom e lattice. W e now aim to construct di erent density wave pattems based on two rules: a) the boson lling $m$ ust be $f=2=3$ and b) the equivalent sites shown in $F$ ig. 1 G $m$ ust have the sam e lling throughout the lattioe ${ }^{\prime 5}$.

Such possible states are sketched in Figs. ${ }_{1} \overline{1}, 1$ and ${ }_{1} \overline{6}$, . T The state denoted by 1 is shown in $F$ ig. $\overline{1} 1$ 3 ordering pattem. H ere all the red and blue sites are
empty (or spin down) while the black and the green sites (both open and closed circles) are occupied (spin up sites). The num bers in the center of the hexagons denote the sum ofm agnetization (in units of $\sim=2$ ) of the sites surrounding the hexagons. For the state 1 shown in F ig. $\underline{1}_{1}$, these take values 0 and 6 .

M ore complicated states 2 and 3 with 9 by 9 ordering pattem are also possible. These are shown in Fig. '81.". For the state 2 the bosons are localized in red, blue, green (closed circle) and black (open circle) sites whereas the green (open circle) and black (closed circle) sites are vacant. The net $m$ agnetization of hexagons for 2 takes values 0,4 and 2 as shown in $F$ ig. 'g. 3 can be sim ilarly obtained from 2 by interchanging the occupations of the black and green sites while leaving the red and the blue sites lled. This has the effect of $2 \$ 4$ for the $m$ agnetization of the hexagons. Interestingly, any linear combinations of 2 and 3 ,
( ) $=\cos ()_{2}+\sin ()_{3}$ for any arbitrary $m$ ixing angle , is also a valid density $w$ ave ordered state. Them ost interesting am ong these states tum out to be the ( =4) which has an 3 by 3 ordering pattem. Such a state corresponds a superposition of lled and em pty boson sites on the green and black (both em pty and lled) sites whereas the red and blue sites are lled. H ere the sum of boson
llings of the sites surrounding the hexagons, takes values 0 and 3 as can be inferred from $F$ ig. $\bar{I}_{1}^{1}$. N otice that the two states 1 and $(=4)$ constructed here has the sam e long-range ordering pattem.

To distinguish betw een ${ }^{2}$ the states 1 and $(=4)$, consider the operator $\mathrm{N}_{\mathrm{b}}=\quad$ i2 hexagon $\mathrm{n}_{\mathrm{i}}$, where $\mathrm{hN} \mathrm{b}_{\mathrm{b}}$ i gives the sum of boson llings of the sites surrounding the hexagon $w$ th center b . The values of $\mathrm{hN} \mathrm{N}_{\mathrm{a}} \mathrm{i}$ for di erent states has been show $n$ in $F$ igs. $\bar{I} 1$ ' and $\overline{1} 9 . W$. W e note that the distinction betw een the states $p$ and $(=4)$ can be $m$ ade by computing the values of $h{ }_{a} N_{a} N_{a+u}$ i which $m$ easures the correlation betw een $N$ operators at sites a and $a+u$ where $u$ is the basis vector for the dice lattice show $n$ in $F$ ig. $\overline{11}$. D eep inside the $M$ ott phase such correlations should vanish for 1 while it $w$ ill rem ain nite for ( $=4$ ). A ltematively, one can also com pute the distribution of the hexagonswith di erent values of HN a i to achieve the sam e goa ${ }^{9}$. Such a distribution, com puted in Ref. ' obtained here.

Recently exact diagonalization study of XXZ m odel on K agom e lattice has been carried out in Ref.1d. Their results concluded the existence of 3 by 3 pattemed RVB state form $=\sim=6 . W$ e note that the RVB state proposed in $R$ ef ${ }^{-10}{ }^{1}$ in shall have identicallong range ordering pattem and $\mathrm{h}{ }_{\mathrm{a}} \mathrm{N}_{\mathrm{a}} \mathrm{Na}_{\mathrm{a}+\mathrm{u}}$ i to the state $(=4)$ obtained in the vortex $m$ ean- eld theory. O f course, a true RVB state, if it exists, is beyond the reach of the $m$ ean-eld treatm ent of the vortex theory. O btaining such states from a dual vortex analysis is left as an open issue in the present work.

FIG. 6: A chart of the inequivalent sites for the $m$ ean- eld vortex state for $v<0 w$ th $\mathcal{J}_{1} j=\dot{\jmath}_{2} j=1$ and relative $=3$ denoted by red, blue, green (open and closed) and black (open and closed) circles. Inequivalent sites are de ned as those which see a di erent vortex environm ent in the surrounding dual lattice. The relevant vortex environm ents are sketched in $F$ igs. ${ }_{1}^{141}$ and ${ }^{5}$

FIG.7: O ne possible density wave states 1 at $f=2=3$ ( $m=1=3$ in units of $\sim=2$ ) when the black and green (both solid and em pty dots) dots have all lled (or spin up) sites while the blue and red sites are empty (spin down). The centers of the hexagons are $m$ arked $w$ ith 6 and 0 respectively and shows the sum of $m$ agnetization (in units of $\sim=2$ ) of the sites surrounding the hexagons. This state shows a 3 by 3 density w ave pattem as can be seen in the gure. A sim ilar state can be obtained for $\mathrm{f}=1=3$ by replacing the bosons w th holes and vice versa.
IV. D ISCUSSIO N

In this work, we have applied the dual vortex theory developed in Refs. 'I' to analyze the super uid and M ott insulating phases of extended B ose H ubbard model (Eq.
 lattice at boson lling $f=1=2 ; 2=3$. The dual theory developed explains the persistence of super uidity in the bosonic $m$ odel at $f=1=2$ of anbitrary sm all vaf ues of $t=U$; $t=V$ seen in the recent $M$ onte- $C$ arlo studies ${ }^{19}$,
and shows that dynam ic localization of vortioes due to destructive $A$ haronov $B$ ohm interference, dubbed as \A haronov-B ohm caging" in Ref. ${ }_{1}^{1}$ this phenom enon. This also o ens an explanation of the absence of $S_{z}$ ordering in the XXZ m odelat zero longitudinalm agnetic eld for arbitrarily large $J_{z}=J_{x}$ as noted in earlier studies ${ }^{111}$. In contrast for $f=2=3$, we nd that there is a direct transition from the super uid to a translationalsym $m$ etry broken $M$ ott phase. $W$ e have derived a Landau-G inzburg action in term $s$ of the dual vortex and gauge elds to describe this transition. W e have shown that the order and the universality class of the transition depends on relevance/irrelevance of the sixth order term in the e ective action. In particular, if this term tums out to be irrelevant, the critical point is decon ned and is accom panied with boson fractionalization. W e have also sketched, w ithin saddle point approxim ation of the vortex action, the possible ordered $M$ ott states that exhibit a 3 by 3 ordering pattem. The results obtained here are_in qualitative agreem ent $w$ ith earlier num erical studies ${ }^{1011} 11$ on related $m$ odels.

W e thank R.M elko and S.W essel for helpful discussions and collaborations on a related pro ject. W e are also grateful to T. Senthil and A.V ishw anath for num erous insightful com $m$ ents. ## APPENDIXA:DUALITY TRANSFORMATION

In this section, we brie $y$ sketch the duality analysis which leads to the dual action (Eq. ${ }^{(16)}$ ). We start from the Bose $H$ ubbard $m$ odelH boson (Eq. $\cdot_{1}^{1} 1_{1}^{\prime \prime}$ ) . First, we follow $R$ ef. ${ }_{1}^{\prime} \overline{1} \bar{l}_{1}^{\prime \prime}$, to obtain an e ective rotor $m$ odel from $H_{\text {boson }}$ given by
where the rotor phase $\left({ }^{\wedge}\right)$ and num ber ( $\hat{N}_{\mathrm{h}}$ operaitors satisfy the canonical comm utation relation $\hat{i}_{i} ; \hat{\mathrm{A}}_{j}=i_{i j}$, denotes lattioe derivative such that $\hat{i}_{i}=\hat{i}_{i+} \hat{i}_{i}$ and $i ;=x ; y$ runs over sites of the kagom, , lattice.

Next, follow ing standard procedures ${ }^{4,177}$, we write dow $n$ the partition function corresponding to $\mathrm{H}_{\text {rotor }}$ in term $s$ of path integrals over states at large num ber of interm ediate time slices separated by width . T hese interm ediate states use basis of $\hat{\mathrm{n}}_{\mathrm{i}}$ and ${ }^{\wedge}$ at altemate tim es. The kinetic energy term of $H_{\text {rotor }}$ which acts on

F IG . 8: D ensity w ave state 2 at $f=2=3$. H ere the hexagons w ith black and green (both solid and open circles) dots have net boson lling 3 (orm agnetization 0 in spin language). T he blue and red sites are lled (spin up). The centers of the hexagons are marked w ith 0,2 and 4 respectively and reects the sum of $m$ agnetization of the sites surrounding the hexagons. This state show s a 9 by 9 density w ave pattem (full pattem not shown in the gure). A nother state 3 w th the sam e periodicity is easily obtained from 2 by sim ply revers ing the direction of the spins (or changing from being lled to being em pty and vige versa) on all the green and the black sites (both open and solid black and green circles) while leaving the blue and the red sites unchanged. This has the e ect of $2 \$ 4$ for the $m$ agnetization of the hexagons. N ote that any linear superposition ( ) = $\cos ()_{2}+\sin ()_{3}$ is also a possible ground state w ith $\mathrm{hm} i=1=3$. The state $(=4)$ has a periodicity of 3 by 3 .
eigenstates of ${ }^{\wedge}{ }_{i}$ can be evaluated as

$$
\begin{array}{lllll} 
& & \exp \mathbb{C o s}( & i)] \\
& \exp \quad J_{i}^{2}=(2 t \quad) \quad i J_{i} & i \tag{A2}
\end{array}
$$

where in the last line we have used the standard V illain approxim ation ${ }^{17}$ and $J_{i}$ are integer elds living on the links of the $K$ agom e lattice. Integrating, over the elds i and de ning the integer eld $J_{i}=\left(n_{i} ; J_{i x} ; J_{i y}\right)$, we get thermk-current representation of the rotor $m$ odel (Eq. A-1

$$
\begin{aligned}
& \text { hiji i }
\end{aligned}
$$

where $f==U+1=2, \quad=V$, and we have rescaled the time interval so that $e^{2}=t \quad=1=U$. The constraint of vanishing divergence of the currents $\left(J_{i}=0\right)$ in the partition function $Z$ com es from integrating out the phase elds. W e now note that this constraint equation can be solved by trading the integer current elds in favor of gauge elds $A_{b}$ which
lives on the links of the dual(dice) lattice and satisfy $J_{i}=\quad A_{b}$. N ote that $\quad A_{b}$ corresponds to the physicalboson density $n_{i} \quad J_{i}$. In term $s$ of these elds the partition function becom es

$$
\begin{equation*}
Z=X_{A_{b}}^{X} \exp {\frac{1}{2 e^{2}}}_{b}^{X}\left(\quad A_{b} \quad f \quad\right)^{2} \tag{A4}
\end{equation*}
$$

Here we have dropped the term proportional to and have assum.ed that it'sm ain role is to renorm alize the coe cient e ${ }^{24}{ }^{4} \mathbf{4}^{2}$. Next, we prom ote the integer-valued elds $A_{b}$ to real valued elds by using Poisson summation form ula and soften the resulting integer constraint by introducing a fugacity term $y_{v} \cos \left(2 A_{b}\right)$. Further, we $m$ ake the $U$ (1) gauge structure of the theory explicit by introducing the rotor elds b on sites of the dual lattice, and $m$ apping $2 A_{b}$ ! $2 A_{b}$
b. This yields

$$
\begin{aligned}
& Z=D A \quad D \exp
\end{aligned}
$$

$$
\begin{align*}
& +y_{v} \cos \left(\begin{array}{lll}
2 & A_{b} & b
\end{array}\right) \tag{A5}
\end{align*}
$$

$W$ e note that $\exp \left(i_{b}\right)$ corresponds to the vortex creation operator for the original bosons $\mathrm{s}^{44}$. Finally, we trade o $\exp \left(i_{b}\right)$ in favorofa \soft-spin" boson eld $b$ as in Ref. 'is' to obtain the nal form of the e ective action

$$
\begin{align*}
& Z=D A \quad D \exp (S) \text {; } \\
& S_{d}={\frac{1}{2 e^{2}}}^{X}\left(\quad A_{b}^{b} \quad f \quad\right)^{2} \\
& y \quad b+e^{2 i A_{b}} b+h: C: \\
& +X^{b} r j b j^{2}+u j b j^{A} \tag{A6}
\end{align*}
$$

## APPENDIX B: TRANSFORMATION OF

H ere we present the details of derivation of the transform ation properties of under rotation by $=3$. The rest of the transform ation properties can be derived in a sim ilar way.

First note that any general term in the H am iltonian $\mathrm{H}_{\text {kinetic }}$ (Eq. $\mathbf{I}_{1}^{-7}$ ) can be w ritten as

$$
a^{(1)} ; a^{(2)} \quad a_{x}^{(1)} ; a_{y}^{(1)} \quad a_{x}^{(2)} ; a_{y}^{(2)} \exp i\left(a^{(1)} ; a^{(2)}\right)^{i}
$$

where

$$
\left(\mathrm{a}^{(1)} ; \mathrm{a}^{(2)}\right)=\frac{2 \mathrm{f}}{\mathrm{P}} \frac{\mathrm{f}}{3} \mathrm{a}_{\mathrm{x}}^{(1)}+\mathrm{a}_{\mathrm{x}}^{(2)} \quad \mathrm{a}_{\mathrm{y}}^{(2)} \quad a_{\mathrm{y}}^{(2)} \quad:(\mathrm{B} 2)
$$

Here ; are site index which can take values $A, B$ or $C$, $\mathrm{a}^{(2)}$ denote a near neighbor site of $\mathrm{a}^{(1)}$, and the phase factor $=\frac{2}{0}_{a_{a_{y}^{(1)}}^{(1)}}^{R_{y}^{(2)}} A_{y} d y$ is obtained $w$ ith the gauge $A=$ $A_{y}=H x$ and $f=0$ where $=H a^{2^{p}} \overline{3}=2$ is the dual ux through an elem entary rhom bus of the dice lattioe ${ }^{8_{1}}$ and 0 is the ux quanta. For exam ple a typical such term can be

$$
\begin{array}{r}
\mathrm{X} \quad \mathrm{~A}^{\mathrm{A} \quad a_{x}^{(1)} ; a_{y}^{(1)} \text { व } a_{x}^{(1)}+1=2 ; a_{y}^{(1)}+{ }^{\mathrm{P}} \overline{3}=2} \\
\mathrm{e}^{2} \text { if }\left(a_{x}^{(1)}+1=4\right)
\end{array}
$$

N ow consider a rotation by an angle $=3$. A fter the rotation, a typical term in the H am iltonian becom es

$$
\begin{array}{cccc}
\text { X } & 0 & a_{x}^{0}(1) ; a_{y}^{0}(1) & 0 \\
a_{x}^{0}(2) & a_{y}^{0}(2) \\
a^{(1)} ; a^{(2)} & e^{2} \text { if }^{0} a_{x}^{0(1)}+a_{x}^{0(2)} & a_{y}^{0(2)} & a_{y}^{0}(2) \\
& e^{p} \overline{3} \tag{B4}
\end{array}
$$

where the rotated coordinates are given in term $s$ of the old coordinates by

$$
\begin{aligned}
& a_{x}^{0}=a_{x}=2 \quad p^{3} a_{y}=2 \\
& a_{y}^{0}=a_{y}=2+{ }^{3} a_{x}=2
\end{aligned}
$$

$N$ ow from the structure of the dige lattice from $F$ ig. $\overline{3}$, we know that such a rotation interchanges $B$ and $C$ sites while transform ing A sites onto them selves. Then com paring term $s,{ }_{-1}^{-1} \overline{1}_{1}$ and $\mathbb{B}_{-1}^{-} \overline{4}$, we see that we need

$$
\begin{equation*}
0 a_{x}^{0} ; a_{y}^{0} e^{i\left(a_{x}^{0} ; a_{y}^{0}\right)}=0\left(a_{x} ; a_{y}\right) \tag{B6}
\end{equation*}
$$

where takesvalues $A, C$ and $B$ for ${ }^{0}=A ; B ; C$. Therefore we have

$$
\begin{equation*}
a^{0}(1) \quad a^{0}(2)=\left(a^{(1)} ; a^{(2)}\right) \quad\left(a^{(1)} ; a^{0(2)}\right) \tag{B7}
\end{equation*}
$$

Fortunately one has a relatively straightforw ard solution
 $a^{0(2)}$

$$
\begin{align*}
& a_{x}=a_{x}^{0}=2+\frac{p}{3} a_{y}^{0}=2 \\
& a_{y}=a_{y}^{0}=2 \tag{B8}
\end{align*} \quad \frac{p}{3 a_{x}}=2
$$

and using Eq. $\frac{.-2}{\operatorname{Br}}$, we get, after som e algebra

$$
\begin{equation*}
\left(a_{x}^{0} ; a_{y}^{0}\right)=2 \text { if } \frac{1}{4} a_{x}^{0} \quad a_{y}^{0} \quad p^{2} 3 a_{x}^{0} a_{y}^{0}=2 \tag{B9}
\end{equation*}
$$

$$
\begin{equation*}
{ }^{0}\left(a_{x} ; a_{y}\right)=e^{i}\left(a_{x} ; a_{y}\right) \quad \circ\left(a_{x} ; a_{y}\right) \tag{B10}
\end{equation*}
$$

where $a_{x}=\left(a_{x}+{ }^{p} \overline{3} a_{y}\right)=2$ and $a "_{y}=\left(a_{y} \quad{ }^{p} \overline{3} a_{x}\right)=2$. This is Eq. 121 of the $m$ ain text where we have used $a_{x} \quad x$ and $a_{y} \quad y$ for notational brevity. All other transform ation properties can be obtained in a sim ilar m anner.

## APPENDIX C:TRANSFORMATION OF VORTEX FIELDS '

H ere we consider the transform ation of ${ }_{1 ; 2}$. First let us concentrate on the translation operator $T_{u}$. U nder action of $T_{u}, \quad!\quad{ }^{0}=\left(x \quad u_{x} ; y \quad u_{y}\right) \exp 4 p$ if $_{u_{x} Y}=\overline{3}$. $N$ ote that for $f=2=3, u_{x}=3 a=2$ and $y=P^{P} \overline{3}=2$, the exponential factor becom e unity. Thus one gets

$$
\left.\begin{array}{rl}
0= & \exp \left[\begin{array}{lll}
i & (n & 1)=3
\end{array}\right](\mathrm{c} ; \\
\mathrm{C} ; 0 \tag{C1}
\end{array}\right)_{1}^{\prime} .
$$

$$
\begin{align*}
r_{1}! & r_{1} \exp (i=3) \\
r_{2}! & r_{2} \exp (2 \quad i=3) \tag{C2}
\end{align*}
$$

Sim ilarly we get the transform ation properties of ${ }^{\prime} 1 ; 2$ under $T_{v}$ and $I_{x}$.
$T$ he transform ation under rotation $=3$ is slightly m ore com plicated. F irst we need to note that for $\mathrm{x}=3 \mathrm{~m} \mathrm{a}=2$ and $y=$ 3na=2, one has

$$
!\left[\left(\begin{array}{ll}
y^{2} & \left.\left.x^{2}\right)=4+{ }^{p} \overline{3}_{x y}=2\right] \tag{C3}
\end{array}=\exp \quad 3 i\left(n \quad m^{\mathcal{Y}}=4+\quad \mathrm{in}^{2}\right.\right.\right.
$$

N ext note that with our choice of origin all the A sites are such that $m+n$ is an even integer and in such cases
$\exp 3 i\left(n \quad m^{2}=4+i n^{2}=\exp \left[\begin{array}{ll}i(m \quad 3 n)=2\end{array}\right]\right.$
for all integers $m$ and $n$. H ence under $a=3$ rotation, we have using Eq. 1

$$
\begin{align*}
0= & h \\
& \exp [\quad i(m+3 n)=6](c ; 0 ; \quad c)_{1}^{\prime} \\
& \exp [\quad 3 \quad i m=2+\quad i n=6](c ; \quad c ; 0)^{\prime} \\
& \quad \exp [\quad i(m \quad 3 n)=2] \\
= & \exp \left[\begin{array}{ll}
i & (m+2 n=3)](c ; 0 ; \quad c)^{\prime}{ }_{1} \\
& +\exp [i n=3](c ; \quad c ; 0)_{2}^{\prime}
\end{array}\right.
\end{align*}
$$

' 2 (1). A sim ilar analysis yields ' 1 (2)! ' ${ }_{1(2)}$ under the operation $R_{2}=3$.

${ }^{12}$ A m ilder version of such a situation $m$ ay occur for square lattice for large $q$ since the depth of the vortex $m$ in im a and the width of the low est H opfstder band becom e sm aller with increasing $q$ as pointed out in Ref. H ow ever, the phenom enon seen here at $q=2$ has a di erent physical origin and is $\mathrm{m} u$ ch m ore robust.
