Con ned optical phonons are discussed for a sem iconductor nanowire of the Ge (Si) prototype on the basis of a theory developed some years ago. In the present work this theory is adapted to a non polar material and generalized to the case when the phonon dispersion law involves both linear and quadratic terms in the wave vector. The treatment is considered along the lines of a continuous medium model and leads to a system of coupled dierential equations describing oscillations of mixed nature. The nanowire is modelled in the form of an in nite circular cylinder and the solutions of the fundamental equations are found. We are thus led to a description of long wavelength optical phonons, which should show a closer agreement with experimental data and with calculations along atom istic models. The presented theory is applied to the calculation of optical phonons in a Genanowire. We have found the dispersion curves for various optical phonon modes. We also normalize the modes and discuss the electron-phonon interaction within the deformation potential approximation.

I. INTRODUCTION

The study of sem iconductor nanowires is of current importance both for device applications and fundamental physics, a point that has been recognized since a certain time ago. More recently, the fabrication of Si and Ge nanowires by means of dierent techniques has been stimulated in view of their relevance in device nanotechnology. The physical properties of these nanostructures are being studied both theoretically and experimentally, while the fabrication of eld-e ect transistors on the basis of this type of systems has been also reported. In the present work we are interested in the phonon properties of non polar nanowires of the Ge and Siprototypes, and, particularly, in the optical phonons. It is well-known that phonon properties play an important role in the considered systems because of their signicance for the analysis of various physical processes, such as, charge and them all transport, optical transitions, etc. Moreover, phononic engineering has been invoked for device application purposes, and it relevant to have a better description of phonon modes.

The analysis of phonon properties in quantum -w ires already has a long history. By applying the long-wavelength approximation, based on continuum approaches, the polar optical phonons were discussed by dierent authors more than a decade ago^{15{18}} (see also Ref. 19 for a more recent paper on the subject). Considering the nanowires made of non polar materials, we must remark the existence of a close related subject: phonons in carbon nanotubes, ^{20,21} an issue revealing outstanding possibilities for present day nanotechnology.

In the case of nanow ires of the Ge or Si prototypes the calculation of optical phonons by means of long-wavelength continuum approaches involves interest by itself, and also for applications. In the framework of the present paper we shall support calculations of the optical phonon modes on a phenomenological theory, which was proposed more than a decade ago for the polar optical phonons in the same kind of nanostructures. $^{22(24)}$ U sing this approach polar optical phonons in quantum -wires were studied in Refs. 17,18. In the Ref. 21 the same theory, but adapted to non polar optical phonons, was applied to the case of carbon nanotubes. In all the above mentioned works it is explicitly assumed that the optical phonons display a dispersion law quadratic with the wave vector, which, in the bulk sem iconductor case is of the form $!^2 = !_0^2$ ²k² and, according to this long-wavelength approximation, should be considered near the -point of the Brillouin Zone (BZ). 25 In the present paper the theory is generalized in order to take account of linear terms in the phonon dispersion law, i.e., we assume a more general dispersion law having the form $!^2 = !_0^2$ 0 k $^{2}k^{2}$ (in the bulk case). Hence, we propose more general equations that in Ref. 21, now involving linear terms, and also we show how they can be solved. It is easy to realize that the additional linear term allows a better description of the optical phonons near the BZ center, in closer correspondence with both experimental evidence and atom istic calculations involving discretized m icroscopic models. In some of the studied cases this linear term becomes essential, and this situation is actually realized in nanostructures based on Si and Ge.

Then, the paper is organized as follows. In Section II we present the fundamental equations, discuss their physical meaning and other details of the approach. In Section III we show how the equations can be solved in the case of a wire of circular cross-section and in nite length. Section IV is devoted to a physical discussion of the results obtained, while the case of a Genanowire is addressed.

We assume that the relative displacement vector usatis esthe following equation:

$$(!^{2} !_{0}^{2})u = {}_{L}^{2}rr u {}_{T}^{2}r r u + i (a r)u + i b(r u) :$$
 (1)

Equation (1) is analogous to that introduced in Refs. 17,18,22{24, just considering that the electric potential is zero (see also Ref. 21). However, new terms were added (two last terms at the rhs. of (1)), which modify the nature of the dierential equation and lead to the linear terms in the phonon dispersion law. The parameter—is the reduced mass density of the two atoms (Ge) in the unit cell, $!_0$ is the optical phonon frequency at the—point of the bulk sem iconductor, and u (r; t) is considered to depend harm onically on the time (exp(i!t)). Parameters L and T (with dimensions of velocity) are introduced to describe the quadratic (parabolic) phonon dispersion and used to the bulk sem iconductor dispersion curve. They were already considered in previous works. Now we are introducing new parameters in the form of vectors a and b, not considered in previous works and leading to linear terms in the phonon dispersion law. The latter vector parameters are also determined by a thing of the bulk sem iconductor dispersion law for the optical phonons. Equation (1) represents a system of three coupled partial dierential equations assumed to describe the conned polar optical phonons in each segment of the sem iconductor heterostructure. The solutions must be matched at the interfaces by applying the boundary conditions for u, which we shall analyze below.

It is important to notice that all the four terms at the rhs. of Eq. (1) may be expressed as the divergence of a tensor $_{ij}$, casted as

$$_{ij} = (_{L}^{2} \ 2_{T}^{2}) (r \ u)_{ij} + _{T}^{2} (u_{j;i} + u_{i;j}) + i (k_{i}u_{j} + a_{j}u_{i}) :$$
 (2)

This tensor could be compared to the stress tensor used in the theory of continuous elastic media, and actually its divergence provides a force density. However, in the framework of the present approach, it should be considered as a phenomenological quantity, which is introduced ad hoc in order to provide a description of dispersive optical phonons in close correspondence with what is seen both experimentally and in atom istic model calculations. In this spirit we do not attempt to explain the tensor ij in terms of the elastic properties of the system, and tensor ij should not be considered a stress tensor in the strict sense of this concept. The sulves ij if ij and ij in the cartesian components, should not be confused with the ii used as a factor. Obviously, in all the equations above we assume an isotropic model for the semiconductor. The short notation u_i , ij denotes the partial derivative with respect to x_j , ij, ij,

Equations (1) and (2) shall be now applied to the nanowire case, assuming it is an in nite cylinder of circular cross-section with radius r_0 . The use of cylindrical coordinates (r; ; z) becomes a natural choice, and the equations must be written in terms of these coordinates, as well as the tensor ij. In the theory of elastic continuous media the standard boundary conditions applied to any interface between two dierent materials are: (1) continuity of the displacement vector u; (2) continuity of the force ux, given by v, where v is the normal unit vector to this surface. Solutions showing divergences at any point of the region must also be disregarded and, in particular, we must avoid singular solutions in the asymptotic limits v: 0;1.

It is convenient to introduce the auxiliary quantities $= r u \cdot T hus$, after sim ple m athem atical manipulations, Eq. (1) is transformed into the following equations:

$$r^2 + q_L^2 = 0;$$
 (3)

$$r^{2} + q_{T}^{2} = \frac{i}{2} a \quad r \quad ;$$
 (4)

w here

$$q_L^2 = \frac{1}{\frac{2}{L}}!_0^2 !^2 + i(a+b) r;$$
 (5)

$$q_T^2 = \frac{1}{\frac{2}{T}}!_0^2 !^2 + ib r :$$
 (6)

Notice that the latter quantities are actually dierential operators in close correspondence with the starting equation. A nother important issue involving Eq. (4) concerns its coupling to Eq. (3). A lithese features make the dierences with respect to previous treatments, 17,18,21 and lead to mathematical complications as a result of our aim of introducing

linear terms in the phonon dispersion law. When applying the equations to the case of an in nite cylinder of radius r_0 led with an isotropic non-polar sem iconductor, we may make use of the translational and rotational symmetries of the system, assuming that the solutions must be proportional to $\exp[i(n+kz)]$, where n=0;1;2; and k plays the role of the wave vector. Moreover, vectors a and bishall be taken along the z-axis, provided that, with this choice, we are led to the appropriate linear dependence on k for the phonon frequencies. Under such conditions $q_{L(T)}^2$ become a parameters linearly depending on the wave vector k and given by: $q_{L}^2 = (!_0^2 !_0^2 !_0^2)$ and $q_{L}^2 = (!_0^2 !_0^2)$

A nother point of central in portance concerns the boundary conditions that should be applied. In this work we shall consider the nanow ire as \free standing", so the appropriate boundary conditions involve zero force at the cylindrical surface of radius r_0 . A fler rewriting tensor i_{ij} in cylindrical coordinates, and realizing that the norm all unit vector N must be taken along the radial direction (N = e_r), we should require the components r_r , r_r and r_r to be equal to zero at r_r = r_0 . Starting from Eq. (2), tediously long but straightforward mathematical manipulations lead us to the following results:

$$_{rr} = {}^{2} \frac{\theta u_{r}}{\theta r} + ({}^{2}_{L} 2 {}^{2}_{T}) \frac{1}{r} \frac{\theta u}{\theta} + \frac{\theta u_{z}}{\theta z} + \frac{1}{r} u_{r} ;$$
 (7)

$$r = \frac{2}{T} \frac{\partial u}{\partial r} + \frac{1}{r} \frac{\partial u_r}{\partial r} \frac{1}{r} u \qquad ; \tag{8}$$

$$z_{r} = \frac{2}{r} \frac{\partial u_{r}}{\partial z} + \frac{\partial u_{z}}{\partial r} + ibu_{r};$$
 (9)

III. SOLUTION OF THE DIFFERENTIAL EQUATIONS

Assuming $(r; ; z) = f(r) \exp[i(n + kz)]$, Eq. (3) leads to

$$\frac{d^2f}{d^2} + \frac{1}{d}\frac{df}{d} + 1 \frac{n^2}{2} f = 0;$$
 (10)

where $= Q_L r$ and $Q_L^2 = q_L^2$ k^2 . Eq. (10) is identied as Bessel equation of order n, and its linearly independent (LI) solutions are usually denoted by J_n () and Y_n (), Bessel functions of the rst and second kind, respectively. In our case we shall apply just the function J_n (), convergent in the interior of the cylinder with 0 r η .

Solutions of Eq. (4), an inhom ogeneous Helm holtz equation for the vector quantity, are more discult to nd. In the 1st place we again shall consider that $(r; ; z) = \exp[i(n + kz)]$. We have found a particular solution of Eq. (4), which is given by

$$_{P} = A e_{z} \quad r \quad ; \quad w \text{ ith } \quad A = \frac{ia}{\frac{2}{T} (q_{T}^{2} - q_{L}^{2})};$$
 (11)

where e_z is a unit vector along the z-axis.

Then, we just have to nd the solution of the hom ogeneous Helm holtz equation $_{\rm H}$, and the general solution shall be given by $_{\rm H}$. As discussed in Ref. 26, page 1766, the two LI solutions of the hom ogeneous Helm holtz equation for a vector function , using cylindrical coordinates, are casted as

$$_{H 1} = r v_1 \quad e_z \quad \text{and} \quad _{H 2} = q_T v_2 e_z + \frac{1}{q_T} r \frac{\theta v_2}{\theta z};$$
 (12)

where the functions v_i (i = 1; 2) satisfy the scalar hom ogeneous H elm holtz equations (r 2 + q_T^2) v_i = 0, with solutions analogous to those of . A first the general solutions for and are found, we can not the corresponding solution of Eq. (1) for u, which shall be obtained from

$$u = \frac{1}{q_T^2} r \qquad \frac{L}{r} r \qquad \frac{ia}{2} e_z : \qquad (13)$$

In the foregoing calculations the involved m athem atical steps are long and tedious, but here we shall report just nalexpressions. We write $u = F(r) \exp[i(n + kz)]$ where $F = F_r e_r + Fe_r + Fe_r + Fe_r$ and e_r , e, and e_r , are the unit vectors of the cylindrical coordinates. Then, we have

$$F_r(r) = J_n^0(Q_L r)C_1 + \frac{ik}{Q_T}J_n^0(Q_T r)C_2 + \frac{in}{Q_T r}J_n(Q_T r)C_3;$$
 (14)

$$F (r) = \frac{in}{Q_L r} J_n (Q_L r) C_1 \frac{nk}{Q_T^2 r} J_n (Q_T r) C_2 J_n^0 (Q_T r) C_3;$$
 (15)

$$F_z(r) = \frac{i(k)}{Q_L} J_n(Q_L r) C_1 + J_n(Q_T r) C_2;$$
 (16)

where $Q_T^2 = q_T^2 - k^2$ and $= a = (\frac{2}{T} - \frac{2}{L})$. The \prime" in the Bessel function denotes the rst derivative with respect to the function's argument and the constants C_i (i = 1; 2; 3) should be determined after application of the boundary conditions. As it was already remarked in Section II, we consider a \free standing" wire, and the boundary conditions read as

$$rr\dot{j}_0 = 0;$$
 $r\dot{j}_0 = 0;$ $rr\dot{j}_0 = 0;$ (17)

indicating that the internal ux of forces through the boundary surface is zero. Taking Eqs. (7), (8), (9), and (17) into account we are lead to the following system of linear homogeneous equations

$$X^{3}$$
 $G_{ij}C_{j} = 0;$
 $j=1$
(18)

where the nine coe cients G_{ij} are explicitly given in the Appendix. The dispersion relations, determining the frequencies of the various phonon modes as functions of the wave vector k, are obtained after solution of the secular equation

$$\det \left[G_{ij}\right] = 0; \tag{19}$$

while the components of the vector F are given as

$$F_r(r)=C = S_1 J_n^0(Q_L r) + \frac{ik}{Q_T} S_2 J_n^0(Q_T r) + \frac{in}{Q_T r} S_3 J_n(Q_T r);$$
 (20)

$$F (r)=C = \frac{in}{Q_{T}r} S_{1}J_{n} (Q_{L}r) \frac{nk}{Q_{T}} S_{2} \frac{1}{Q_{T}r} J_{n} (Q_{T}r) S_{3}J_{n}^{0} (Q_{T}r);$$
 (21)

$$F_z(r)=C = \frac{i(k)}{O_T} S_1 J_n(Q_T r) + S_2 J_n(Q_T r);$$
 (22)

where the functions S_i (i = 1; 2; 3) are given in the Appendix.

IV. NORMALIZATION OF THE PHONON STATES

The determ ination of the constant C is made by normalization of the oscillation modes, which requires to transform the classical eld u into a quantum – eld operator. This is formally done in the form $u \,! \, \hat{u} = u \, \hat{a}_{n\,;\,k}$, where $\hat{a}_{n\,;\,k}$ are second quantization bosonic operators. Operator $\hat{a}_{n\,;\,k}$ ($\hat{a}_{n\,;\,k}^{y}$) annihilates (creates) a $n\,;\,k$ optical phonon. We must also transform the classical kinetic energy for the oscillations to a quantum — mechanical operator by applying the rule

$$W_{kin} = \frac{1}{2} \quad \underbrace{u}_{kin} = \frac{1}{2} \cdot \underbrace{u}_{kin} = \underbrace{u}_{$$

w here

$$\hat{H}_{ph} = \frac{1}{4} !^{2} \hat{u}^{y} \hat{u} + \hat{u} \hat{u}^{y} d^{3}r = \frac{1}{2} !^{2} u u d^{3}r = \frac{1}{4} !^{2} :$$
 (24)

In Eq. (24) \hat{H}_{ph} describes the free phonons ham iltonian operator, while its herm itian character is ensured by construction. Requiring the latter expression to be given in standard form for phonons of the type \n;k" (actually, we must have !!! $_{nk}$) $\hat{H}_{ph} = h!_{nk}$ \hat{a}_{nk} \hat{a}_{nk} \hat{a}_{nk} , \hat{a}_{nk} \hat{a}_{nk} , \hat{a}_{nk} \hat{a}_{nk} , \hat{a}_{nk} one can nally write the normalization constant C by

$$C_{n;k} = \frac{b}{L !_{n;k} M_{n;k}}; \qquad (25)$$

where L is a normalization length (taken along the z axis) and $M_{n;k} = {R \choose r}(r)F_r(r) + F(r)F(r) + F_z(r)rdr=J_{n;k}J_n$. The explicit expressions for $M_{n;k}$ involve rather complicated integrations of the Bessel functions and may be calculated numerically for each value of k and ! corresponding to the possible oscillation modes.

For optical phonons in a non polar sem iconductor the electron-phonon ham iltonian is given through the deform ation potential approximation and, for an isotropic sem iconductor, is proportional to r u. Then, it is interesting to discuss this latter quantity, which provides an estimative of the interaction strength.

V. DISCUSSION OF RESULTS

W ith the aim of illustrating the foregoing theory, we consider a Genanowire. The Gephysical parameters are given in Table I.

TABLE I: Ge param eters

m aterial	a_0 [10 8 cm]	[g=am ³]	$!_0$ [cm 1]	$_{\rm T}$ [10 $^{\rm 5}$ cm =s]	_L [10 ⁵ cm =s]	$a[10^{18} \text{ cm} = \text{s}^2]$	$b[10^{18} \text{ cm} = \text{s}^2]$
Ge	5.66	5.32	305	3.48	3.55	-6.26	3.59

The parameters $_{\rm T}$, $_{\rm L}$, a and b were determined by the authors by a tting of the bulk sem iconductor phonon dispersion law reported in Ref.27, considering dispersion along the (001) direction and embracing approximately 50 40% of the BZ near the point. Parameter! $_{\rm 0}$ was taken from the same reference, while the other parameters can be found in Ref. 28.

In Fig. 1 we depict the dispersion relation for several axis-sym m etric m odes (n = 0) taking r_0 = 10 7 cm . The frequency is in units of cm 1) and the wave vector k is in units of 2 =a₀, where a₀ is the lattice parameter for the bulk sem iconductor). The curves were obtained from Eq. (19) taking n = 0. Let us emphasize that these modes do not present torsional oscillations, and they result from a combination of radial breathing vibrations together with vibrations along the cylinder axis (axial oscillations). The latter oscillations are not purely longitudinal as it is sometimes argued, but a mixture of LO and TO oscillations. However, at k = 0 the axis-sym metric oscillations separate into pure LO and TO vibrations, a fact we have used for the labelling of the dierent modes.

Notice that for the curves corresponding to the modes TO $_2$ and LO $_3$ there is an interval of k values (approxim ately between 0.5 and 0.63) where the curves are interrupted, and no frequencies are reported. This region obviously corresponds to an anticrossing of the mentioned modes. O focurse, in the real case, there must be oscillation frequencies and the interrupted curves may be interpreted as a limitation of our approach, which is not able to describe such oscillation modes. However, it is worth to mention that the observed failure has nothing to due with the anticrossing elect by itself. The theory we are applying is essentially valid not too far from the k=0 region, and we are actually extrapolating it beyond this region. This latter issue should be seen as a singular failure of the applied treatment, which, otherwise is giving a rather good description of the dispersion law for these modes. We have set $r_0=10^{-7}$ cm, a relatively small radius which, however, is typical for this kind of nanowires. For such thin nanowire the number of physically possible optical phonon modes is rather limited and, in fact, Fig. 1 displays a few more modes than actually present. In the framework of the current paper one important contribution is to stress the importance of taking the role of the linear term into account we have added to our equations. It is easy to convince ourselves of this latter issue: making the linear term sequal to zero the general structure of the dispersion law depicted in Fig. 1 is

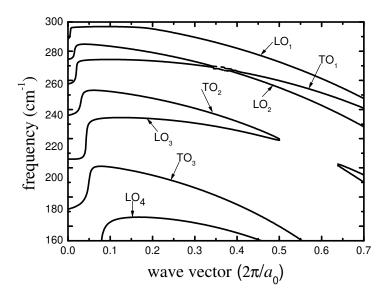

FIG. 1: D ispersion curves for the axis-symmetric modes (n=0). The frequency is in units of cm 1 and the wave vector k in units of 2 = a_0) and we take $r_0 = 10^{-7}$ cm.

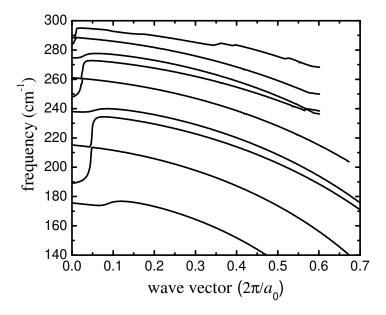

FIG.2: D ispersion curves for the exural modes for n=1 taking $r_0=10^{-7}$ cm. The frequency is in units of cm $^{-1}$) and the wave vector k in units of $2=a_0$).

subjected to signicant changes. The other interesting point is to compare with experimental results or calculations based upon microscopic (atomistic) approaches. Unfortunately, in the revised literature we have not found reports on optical phonons for this particular type of Genanowires.

In Fig. 2 we show the dispersion curves for the so-called exural modes taking again $r_0 = 10^{-7}$ cm and for $r_0 = 1$. These modes involve all kinds of possible vibrations: radial, axial and torsional. Torsional modes can be considered for any $r_0 > 0$ and we are analyzing the case with $r_0 = 1$. In the chosen frequency interval (140 < ! < 300 cm r_0), involving the higher frequency values, just nine modes are present. We should remark that, for the exural modes, the oscillations have always a mixed character and cannot be separated into pure LO and TO oscillations. In contrast with the axis-symmetric modes the mixing is present even at r_0 , and then we cannot classify the modes in the same way as we did in Fig.1.0 ther feature clearly seen in Fig.2 is the presence of several anticrossing regions: curves belonging to the same symmetry cannot cross each other and are repelled whenever they get too close. Finally, there are several curves (those with the higher frequencies) that are interrupted for the higher values of k (especially,

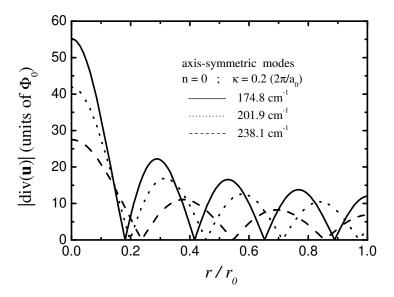

FIG .3: Absolute value of the divergence of vector u (in units of $_0$) as a function of $r=r_0$ for the axis-sym m etric m odes (n = 0). We xed k=0.2 ($2=a_0$) and considered the frequencies 174.8, 201.9 and 238.1 cm 1 corresponding to three possible modes displayed in Fig. 1.

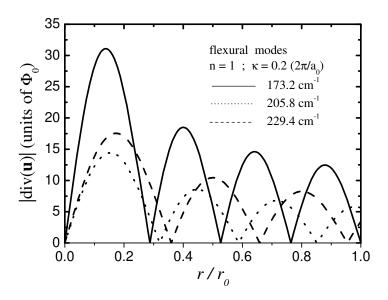

FIG. 4: Absolute value of the divergence of vector u (in units of $_0$) as a function of $r=r_0$ for the exural modes (n = 1). We xed k=0.2 ($2=a_0$) and considered the frequencies 173:18, 205:8 and 229:4 cm 1 corresponding to three possible modes displayed in Fig. 2.

in the region k > 0.6, in units of $2 = a_0$). The explanation for this e ect is the same as in Fig.1: a failure of the used approximation, which is actually valid for values of k not too far from k = 0. However, we must again remark that the theory actually gives a very useful description of the considered modes for a relatively wide interval of k (60 70% of the BZ).

B esides the dispersion curves, we nd interesting to analyze the quantity given by r u div (u), as a function of r in the interval r r_0 . The point is that this quantity is proportional to the electron-phonon interaction according to the deform ation potential approximation, and then can give us an estimative of the strength of this interaction. We have taken the divergence of vector u, given in Eq. (22) in cylindrical coordinates, together with the normalization constant, Eq. (25), which was evaluated numerically.

In Fig. 3 we plot the absolute value of the mentioned quantity (jdiv (u)j) in units of $_0 = h=L \cdot !_0 r_0^4 l^{(1-2)}$ as a function of $r=r_0$. We show three curves corresponding to the axis-symmetric modes (n = 0) with a xed value of k

 $(k = 0.2)(2 = a_0)$ and three possible frequencies (! = 174%; 2019; 238:1 cm⁻¹) involving three dierent modes (the m odes LO₄, TO₃, and LO₃ respectively). In Fig. 3 the oscillatory behavior of the interaction potential strength is seen, a clearly understandable fact if we realize that it is given as a combination of Bessel functions. At the point r = 0 the quantity is not zero, while the points of maxima determine the values of rwhere the interaction strength should be stronger. Moreover, for the modes with increasing values of the frequency the strength of the interaction gets weaker. When plotting the absolute value of div (u) we have lost all information concerning its dependence with respect to and z. However, we retained the important information about its r dependence. In should also be kept in m ind that, in order to obtain a better estimation of the electron-phonon interaction strength, it is necessary to evaluate the corresponding matrix elements involving the electron wave functions. If the electron wave function is peaked at a point where the deform ation potential has a low value, we should realize that the interaction strength still m ay be strong depending on the relative weight of both e ects. The plot displayed in Fig. 4 is quite sim ilar to that of Fig. 3, but now considering the n = 1 case (exural modes). We again see the oscillatory behavior for the same reason as in Fig. 3, but now the involved quantity is zero at r = 0, and the calculated strengths are somewhat lower. It is also seen that the deform ation potential is not lower for higher values of the frequency. In fact, the intermediate frequency mode leads to weaker intensities that the lower frequency mode. The same comments as those done for Fig. 3 can be made.

In conclusion, we have calculated the optical phonon modes for a Genanowire in the framework of a continuum approach. The applied theoretical treatment was adapted to the non-polar case, and also was improved by incorporating the important linear terms in the wave vector. In this context we expect the theory to provide better results than those given by other long wavelength treatments. But, as was already remarked, we do not presently have experimental results or microscopic atomistic calculations allowing a desirable comparison with our indings. Nevertheless, and due to the current interest in the study of this kind of nanostructures, we think the results of the present work should be useful in the way to get a better understanding of Ge and Sinanowires.

Appendix A.

The nine functions G_{ij} , appearing in Eq. (18), are given in the form

$$G_{11} = {}^{2}_{L}Q_{L} \qquad \frac{T^{n}}{L} \qquad 1 \qquad \frac{T^{n}}{L} \qquad () = {}^{2} \qquad 1 \qquad J_{n}() \qquad 2 \qquad \frac{T^{n}}{L} \qquad J_{n}^{0}() = ;$$

$$G_{12} = \frac{2ik \frac{T}{2}}{2} (n^{2} \quad {}^{2})J_{n}() \qquad J_{n}^{0}() ;$$

$$G_{13} = \frac{2in \frac{T^{2}Q_{T}}{2}}{2} [J_{n}() \qquad J_{n}^{0}()];$$

$$G_{21} = \frac{2in \frac{T^{n}Q_{T}}{2}}{2} [J_{n}() \qquad J_{n}^{0}()];$$

$$G_{22} = \frac{2nk \frac{T}{2}}{2} [J_{n}() \qquad J_{n}^{0}()];$$

$$G_{33} = \frac{T^{n}Q_{T}}{2} \qquad 2 \qquad J_{n}^{0}() + (^{2} \qquad 2n^{2})J_{n}() ;$$

$$G_{31} = i \frac{T^{n}Q_{T}}{2} \qquad 2 \qquad J_{n}^{0}() + (^{2} \qquad 2n^{2})J_{n}();$$

$$G_{32} = \frac{T^{n}Q_{T}}{2} \qquad 1 \qquad ()^{2} + bm_{0} = (T^{n}_{T}) \qquad J_{n}^{0}();$$

$$G_{33} = \frac{nk \frac{T^{n}Q_{T}}{2}}{2} \qquad 1 + bm_{0} = (T^{n}_{T}) \qquad J_{n}^{0}();$$

$$G_{33} = \frac{nk \frac{T^{n}Q_{T}}{2}}{2} \qquad 1 + bm_{0} = (T^{n}_{T}) \qquad J_{n}^{0}();$$

$$G_{33} = \frac{nk \frac{T^{n}Q_{T}}{2}}{2} \qquad 1 + bm_{0} = (T^{n}_{T}) \qquad J_{n}^{0}();$$

$$G_{33} = \frac{nk \frac{T^{n}Q_{T}}{2}}{2} \qquad 1 + bm_{0} = (T^{n}_{T}) \qquad J_{n}^{0}();$$

$$G_{33} = \frac{nk \frac{T^{n}Q_{T}}{2}}{2} \qquad 1 + bm_{0} = (T^{n}_{T}) \qquad J_{n}^{0}();$$

$$G_{33} = \frac{nk \frac{T^{n}Q_{T}}{2}}{2} \qquad 1 + bm_{0} = (T^{n}_{T}) \qquad J_{n}^{0}();$$

$$G_{33} = \frac{nk \frac{T^{n}Q_{T}}{2}}{2} \qquad 1 + bm_{0} = (T^{n}_{T}) \qquad J_{n}^{0}();$$

where = r_0 , = kr_0 , = $Q_L r_0$, and = $Q_T r_0$. On the other hand, the functions S_i , present in Eqs. (20), (21) and (22), are de ned as

$$S_1 = G_{32}G_{23}$$
 $G_{22}G_{33}$;
 $S_2 = G_{21}G_{33}$ $G_{31}G_{23}$;
 $S_3 = G_{31}G_{22}$ $G_{32}G_{21}$:
