# Scaling in a general class of critical random B oolean netw orks 

Tam ara M inaljev and Barbara D rossel<br>Institut fur Festkorperphysik, T U D arm stadt, H ochschulstra e 6, 64289 D arm stadt, G erm any (D ated: D ecem ber 28, 2021)

#### Abstract

W e derive analytically the scaling behavior in the therm odynam ic lim it of the num ber ofnonfrozen and relevant nodes in the $m$ ost general class of critical $K$ au $m$ an netw orks for any num ber of inputs per node, and for any choice of the probability distribution for the Boolean functions. By de ning and analyzing a stochastic process that determ ines the frozen core we can prove that the $m$ ean num ber of nonfrozen nodes in any critical netw ork $w$ th $m$ ore than one input per node scales $w$ ith the netw ork size N as $\mathrm{N}^{2=3}$, w ith only $\mathrm{N}^{1=3}$ nonfrozen nodes having two nonfrozen inputs and the num ber of nonfrozen nodes w ith more than two inputs being nite in the therm odynam ic lim it. $U$ sing these results we can conclude that the $m$ ean num ber of relevant nodes increases for large $N$ as $N^{1=3}$, w ith only a nite num ber of relevant nodes having two relevant inputs, and a vanishing fraction of nodes having $m$ ore than three of them. It follow $s$ that all relevant com ponents apart from a nite num ber are sim ple loops, and that the m ean num ber and length of attractors increases faster than any pow er law w ith netw ork size.

## I. INTRODUCTION

$R$ andom B oolean netw orks are often used as generic m odels for the dynam ics of com plex system $s$ of interacting entities, such as social and econom ic netw orks, neural netw orks, and gene or protein interaction netw orks (1]. The sim plest and $m$ ost $w$ idely studied of these models w as introduced in 1969 by K au m an [2] as a model for gene regulation. T he system consists of $N$ nodes, each of which receives input from K random ly chosen other nodes. The netw ork is updated synchronously, the state of a node at tim e step tbeing a B oolean function of the states of the $K$ input nodes at the previous tim e step, t 1. T he B oolean updating functions are random ly assigned to every node in the netw ork, and together w ith the connectivity pattem they de ne the realization of the netw ork. For any initial condition, the netw ork eventually settles on a periodic attractor.

O f special interest are critical netw orks, which lie at the boundary betw een a frozen phase and a chaotic phase [3, 4]. In the frozen phase, a perturbation at one node propagates during one tim e step on an average to less than one node, and the attractor lengths rem ain nite in the $\lim$ it N ! 1 . In the chaotic phase, the di erence betw een tw o alm ost identical states increases exponentially fast, because a perturbation propagates on an average to $m$ ore than one node during one tim e step [5]. W hether a netw ork is frozen, chaotic, or critical, depends on the connectivity K as well as on the weights of the di erent B oolean functions. If these weights are chosen appropriately, critical netw orks can be created for any value of K .

The nodes of a critical netw ork can be classi ed according to their dynam ics on an attractor. First, there are nodes that are frozen on the sam e value on every attractor. Such nodes give a constant input to other nodes and are otherw ise irrelevant. T hey form the frozen core of the netw ork. Second, there are nodes whose outputs
go only to irrelevant nodes. Though they m ay uctuate, they are also classi ed as irrelevant since they act only as slaves to the nodes determ ining the attractor period. Third, the relevant nodes are the nodes whose state is not constant and that control at least one relevant node. T hese nodes determ ine com pletely the num ber and period of attractors. If only these nodes and the links betw een them are considered, they form loops w ith possibly additional links and chains of relevant nodes w ithin and betw een loops. T he recognition of the relevant elem ents as the only elem ents in uencing the asym ptotic dynam ics $w$ as an im portant step in understanding the attractors of $K$ au $m$ an netw orks. The behavior of the frozen core was rst studied by F lyvb jerg [6]. T hen, in an analytical study of $K=1$ netw orks $F$ lyvb jerg and $K$ jaer [7] introduced the concept of relevant elem ents. This concept w as generalized to general critical netw orks by B astolla and Parisi [8, 9]. T hey gained insight into the properties of the attractors of the critical netw orks by using num erical experim ents based on the $m$ odular structure of the relevant elem ents. F inally, Socolar and K au m an [10] found num erically that for critical $K=2$ netw orks the m ean num ber of nonfrozen nodes scales as $N_{n f} \quad N^{2=3}$, and them ean num ber of relevant nodes scales as $N_{\text {rel }} \quad N^{1=3}$. The sam e result is hidden in the analytical work on attractor num bers by Sam uelsson and Troein [11], as w as show $n$ in [12]. A $n$ explicit analytical derivation of these and other scaling laws was given in [13]. For $K=1$, these pow er law $s$ are $N_{n f} \quad N$ and $N_{\text {rel }} \quad N^{1=2}$, since there is no frozen core in a $K=1$ critical netw ork.

In this work, we will derive the scaling behavior of the num ber of nonfrozen and of relevant nodes in critical $K$ au $m$ an netw orks $w$ ith $K$ 3. Since the scaling behavior is di erent for $K=1$ and $K=2$, one could expect that the exponents are generally K -dependent. H ow ever, we w ill show that the exponents $2=3$ and $1=3$ found for $K=2$ are valid also for larger $K$ and for allpossible probability distributions of the B oolean fiunctions, as long as
the network is critical. We also obtain results for the num ber of nonfrozen nodes $w$ th tw $o$ and $m$ ore nonfrozen inputs, and for the num ber of relevant nodes $w$ th two and $m$ ore relevant inputs.
$T$ he outline of this paper is the follow ing. In the next section, we introduce a stochastic process that yields the frozen core in $K=3$ netw orks. Them ean- eld-theory for this process is presented in Section III, and an im proved treatm ent including uctuations is presented in Section IV, yielding the scaling behavior of the num ber of nonfrozen nodes in criticalnetw orks. T he next three sections are devoted to special points in param eter space, where the stochastic process does not generate all of the frozen core. In Sections V and V I those points are considered, where the stochastic process gives a sm aller frozen core, and it is show $n$ that \self-freezing loops" generate the rest of the frozen core. In Section V II, we consider points in param eter space, where the stochastic process does not generate any frozen nodes, and where self-freezing loops are responsible for all of the frozen core. F inally, in Sections VIII and IX we evaluate the case K 4 and the scaling behavior of the relevant nodes and attractor properties. Section X discusses the im plications of our results.

## II. A STOCHASTIC PROCESS THAT LEADS TO THE FROZEN CORE

From now on, we set K = 3 and derive explicitly the scaling behavior of the nonfrozen nodes. T he generalization to larger $K$ and the scaling behavior of the relevant nodes w ill be discussed later. T he rst step of the calculation, which is perform ed in this section, consist in de ning a stochastic process that determ ines the frozen core. $T$ his process is inspired by the one used in [13] for $K=2$, how ever it needed to be m odi ed before it could be generalized to larger K. T he treatm ent presented in the follow ing is based on the existence ofnodes $w$ ith constant functions (functions in which the output is xed irrespectively of the input) and it therefore applies to all criticalm odels that have a nonzero fraction of constant functions. N etw orks w ith no constant functions, and in particular netw orks w ith only canalyzing functions w ill be discussed separately.

F lyvb jerg [6] was the rst one to use a dynam icalprocess that starts from the nodes $w$ ith constant update functions and determ ines iteratively the frozen core. Perform ing a m ean- eld calculation for this process, he could identify the critical point. $W$ e de ne in the follow ing a process that goes beyond $m$ ean- eld theory and gives exact results for the frozen core. W e consider the ensem ble of all netw orks of size $N$ w th a xed number of nodes w ith constant update functions. All nodes with a constant update function are certainly part of the frozen core. W e construct the frozen core by determ in ing stepw ise all those nodes that becom e frozen due to the inuence of a frozen node. In the language of [10], this process determ ines the \clam ped" nodes.

In a $\mathrm{K}=3$ network, each node has 3 inputs, and there are consequently $2^{2^{3}}=256$ possible Boolean functions. In order to specify a m odel, one has to specify the probabilities for a node to choose each of these fiunctions. Instead of perform ing the calculation in term s of all these param eters, it tums out that three param eters are su cient. For the $K=2$ netw orks, we introduced 3 param eters corresponding to the occurrence of three types of B oolean functions. For larger $K$, there are $m$ ore types of B oolean functions, and we use therefore a di erent set of param eters. T he rst param eter is ,which is the proportion of nonfrozen nodes in the netw ork. 1
is therefore the proportion of nodes w ith a constant update function. W e require < 1 for the calculation perform ed in this and the follow ing section. T he case $=1$ w ill be discussed further below. The second param eter is $!_{2}$, which is the probability that a random ly chosen node that does not have a constant update function w ill becom e a frozen node when one of its 3 inputs is connected to a frozen node. If one input of a node is xed at som e value, the node has e ectively tw o inputs left. W e now consider those nodes that have not becom e frozen by xing one input, i.e. we are considering the proportion $1 \quad!_{2}$ of all nonfrozen nodes. $T$ he param eter $!_{1}$ is then the probability that such a node becom es frozen w hen one ofthe rem aining tw o inputs is connected to a frozen node. $T$ his probability can again be expressed in term $s$ of the probabilities of the di erent possible update functions. $T$ hus all the netw orks $w$ th the sam e param eters $!_{2},!_{1}$ and $w$ ill be treated as of the same type. A s we will see below, the properties we are interested in will be the sam e not only for the functions that belong to the sam e type of the netw ork (i.e., that have the sam e param eters but possibly di erent B oolean functions) but also for the di erent types as long as their param eters are such that the netw ork satis es the criticality condition (3) derived below. This m eans that we can have critical netw orks w ith all possible choioes of Boolean functions and that they will all be characterized by the sam e exponents as a consequence ofbeing critical.

Now, let us de ne the stochastic process that deter$m$ ines the frozen core. For this purpose, we di erentiate 4 types of nodes, the num bers of which will change during the process, and we place these nodes in 4 di erent \containers". Initially, all nodes with constant functions are placed in a container labelled $F$, and the rem aining nodes in a container labelled $\mathrm{N}_{3}$. In this container are all those nodes, for which we do not yet know if they are connected to a frozen node. The other two containers, labelled $\mathrm{N}_{2}$ and $\mathrm{N}_{1}$, are initially em pty. They w ill contain nodes w ith one and two frozen inputs that are them selves not (yet) frozen. Since the num ber of nodes in the di erent containers is going to change during our stochastic process, we denote the initial values of num bers of nodes in the containers as $N_{f}^{\text {in } i}, N_{2}^{\text {in } i}=N_{1}^{\text {in } i}=0$ and $\mathrm{N}_{3}^{\text {in } i}$, and the total num ber of nodes as N ini (this is the actual num ber of nodes in the netw ork). T he contents of the containers willchange with tim e. The \tim e"
we are de ning here is not the realtim e for the dynam ics of the system. Instead, it is the tim e scale for a stochastic process that we use to determ ine the frozen core. D uring one tim e step, we choose one node from the container $F$ and determ ine the in uence of this node on the nodes connected to it. A fter determ ining its in uence we will rem ove it from the system, and the num ber of nodes $N$ in the system is reduced by 1 . N ow, for each nonfrozen node in container $N_{3}$ we ask whether it receives input from the chosen frozen node. If this is the case it freezes w ith probability $!_{2}$ due to the in uence of this node and $m$ oves to container F. W ith probability 1 ! 2 it does not becom e frozen and $m$ oves to container $N_{2}$. In one tim e step, we therefore $m$ ove each node of container $N_{3}$ w th probability $3!{ }_{2}=\mathrm{N}$ to the container F , and w ith probability $3\left(1 \quad!_{2}\right)=N$ to the container $\mathrm{N}_{2}$. Sim ilarly, a node from the container $\mathrm{N}_{2}$ receives input from the chosen frozen node w ith probability $2=\mathrm{N}$, and it w ill then becom e frozen w ith probability ! 1 and w ill be placed in the container $F$. If it does not freeze, we place it in container $\mathrm{N}_{1}$, where we nd all those nodes that have tw o inputs from frozen nodes and are not frozen. W hen nodes from this container choose a frozen node as an input, they autom aticly becom e frozen. D uring this process, the probabilities $!_{2}$ and $!_{1} \mathrm{w}$ ill not change since the nodes from containers $\mathrm{N}_{3}$ and $\mathrm{N}_{2}$, for which we are in every tim e step determ ining whether they are going to freeze, are chosen at random, and $m$ oving them from the containers will not change probability distribution of the functions of the nodes left in the containers. In the next tim e step, we choose another frozen node from container $F$ and determ ine its e ect on the other nodes. Som e nodes $m$ ove again to a di erent container, and the chosen frozen node is rem oved from the system. W e repeat this procedure until we can not continue because either container $F$ is em pty, or because all the other containers are em pty. If container $F$ becom es em pty, we are left w ith the nonfrozen nodes. W e shall see below that $m$ ost of the rem aining nodes are in container $N_{1}$, w th the proportion of nodes left in containers $\mathrm{N}_{2}$ and $\mathrm{N}_{3}$ vanishing in the lim it N in ${ }^{1}$ ! 1 . If all containers apart from container $F$ are em pty at the end, the entire netw ork becom es frozen. This $m$ eans that the dynam ics of the netw ork goes to the same xed point for all in itial conditions.

## III. MEAN FIELDAPPROXIMATIONAND THECRITICALITYCONDITION

Let us rst describe th is process by determ in istic equations that neglect uctuations around the average change of the num ber of nodes in the di erent containers. As long as all containers contain large num bers of nodes, these uctuations are negligible, and the determ in istic description is appropriate. The average change of the
node num bers in the containers during one tim e step is

$$
\begin{align*}
& \mathrm{N}_{3}=\frac{3 \mathrm{~N}_{3}}{\mathrm{~N}} \\
& \mathrm{~N}_{2}=\frac{2 \mathrm{~N}_{2}}{\mathrm{~N}}+\left(\begin{array}{ll}
1 & !_{2}
\end{array}\right) \frac{3 \mathrm{~N}_{3}}{\mathrm{~N}} \\
& \mathrm{~N}_{1}=\frac{\mathrm{N}_{1}}{\mathrm{~N}}+\left(\begin{array}{ll}
1 & !_{1}
\end{array}\right) \frac{2 \mathrm{~N}_{2}}{\mathrm{~N}}  \tag{1}\\
& \mathrm{~N}_{\mathrm{f}}=1+\frac{\mathrm{N}_{1}}{\mathrm{~N}}+!_{1} \frac{2 \mathrm{~N}_{2}}{\mathrm{~N}}+!_{2} \frac{3 \mathrm{~N}_{3}}{\mathrm{~N}} \\
& \mathrm{~N}_{2}=1
\end{align*}
$$

T he total num ber of nodes in the containers, N , can be used instead of the tim e variable, since it decreases by one during each step. The equation for $\mathrm{N}_{3}$ can then be solved by going from a di erence equation to a di erential equation,

$$
\frac{\mathrm{N}_{3}}{\mathrm{~N}}, \frac{\mathrm{dN}_{3}}{\mathrm{dN}}=\frac{3 \mathrm{~N}_{3}}{\mathrm{~N}} ;
$$

which has the solution

$$
N_{3}=N^{3} \frac{N_{3}^{\text {in } i}}{\left(\mathbb{N}^{\text {in } i}\right)^{3}}=\frac{}{\left(\mathbb{N}^{\text {in } i}\right)^{2}} N^{3} ;
$$

where $=\frac{\mathrm{N}_{3}^{\text {in } i}}{\mathrm{~N}^{\text {in } i}}$. Sim ilarly, we nd

$$
\begin{align*}
\mathrm{N}_{2}= & 3\left(1 \quad!_{2}\right) \frac{\mathrm{N}_{\text {in i }}}{\mathrm{N}}
\end{align*}
$$

W hen $13\left(1 \quad!_{1}\right)\left(1 \quad!_{2}\right)<0$, the equation $N_{f}=0$, which represents the stopping condition for the process, has a solution for an nonzero value N . This solution shows that the num ber of nonfrozen nodes in each container is proportional to $\mathrm{N}^{\text {in } i}$. This m eans that on an average a nonfrozen node has $m$ ore than one nonfrozen input. A perturbation at one node propagates during one tim e step on an average to $m$ ore than one node and we are obviously in the chaotic phase.

For $1 \quad 3\left(\begin{array}{lll}1 & !_{1}\end{array}\right)\left(\begin{array}{ll}1 & !_{2}\end{array}\right) \quad 0$ the equation $\mathrm{N}_{\mathrm{f}}=0$ does not have a nonzero solution for $\mathrm{N} 2\left[0 ; \mathrm{N}^{\text {in }}\right]$. In this case, wew illstop the process w hen $\mathrm{N}_{\mathrm{f}}$ dropsbelow 1 . W e are in the frozen phase, or we have a critical system.

In the case $1 \quad 3\left(1 \quad!_{1}\right)\left(1 \quad!_{2}\right)>0$, the values $N_{3}$ and $\mathrm{N}_{2}$ will sink below 1 when N becom es of the order $\overline{\mathrm{N}}{ }^{\text {in } \mathrm{i}}$, and the higher-order term s contributing to $\mathrm{N}_{\mathrm{f}}$ and $N_{1}$ can be neglected com pared to the rst one. For sm aller $N$, only frozen nodes and nodes with one input
are left. W hen $\mathrm{N}_{\mathrm{f}}$ falls below 1, there rem ain only a constant num ber of the nodes of type $\mathrm{N}_{1}$,

$$
N_{1}, \frac{3\left(1 \quad!_{1}\right)\left(1 \quad!_{2}\right)}{13\left(1 \quad!_{1}\right)\left(1 \quad!_{2}\right)}:
$$

The netw ork is essentially frozen, with only a nite num ber of nonfrozen nodes in the $\lim$ it $N{ }^{\text {ini }}$ ! 1 . If we now choose the inputs for these nodes, we obtain sim ple loops w ith trees rooted in the loops. This property of the frozen phase was also found in [10].

W hen param eters of the netw orks are such that

$$
\begin{equation*}
1 \quad 3\left(1 \quad!_{1}\right)\left(1 \quad!_{2}\right)=0 \tag{3}
\end{equation*}
$$

is ful lled, we are at the boundary betw een frozen and chaotic phase in the param eter space. T hus the netw ork is critical. Since the stochastic process stops at $\mathrm{N}_{\mathrm{f}}=1$, we have

$$
1=\frac{\left(1 \quad 2!_{1}\right.}{1} \begin{array}{ll}
1 & \left.!_{1}\right)
\end{array} \frac{\left(\mathbb{N}^{\text {end }}\right)^{2}}{\mathbb{N}^{\text {in i }}}+\frac{!_{1}}{\left(1 \quad!_{1}\right)} \quad \frac{\left.\mathbb{N}^{\text {end }}\right)^{3}}{\left(\mathbb{N}^{\text {in } i}\right)^{2}}:
$$

In the $\lim$ 辻 $N^{\text {ini }}$ ! 1 the rst term is dom inant and the num ber of non frozen nodes would scale w ith the square root of the netw ork size if the determ inistic approxim ation to the stochastic process was exact. W e shall see below that including uctuations changes the exponent from $1=2$ to $2=3$. The nal num ber of $\mathrm{N}_{2}$-nodes for the determ in istic process for the critical netw orks is independent of netw ork size, and the nal num ber of $\mathrm{N}_{3}$-nodes is $\quad\left(\mathbb{N}^{\text {in }}\right)^{1=2}$ and vanishes for $N^{\text {in } i}$ ! 1 . We shall see below that the uctuations change these tw o results to $\mathrm{N}_{2} \quad\left(\mathrm{~N}^{\text {in } \mathrm{i}}\right)^{1=3}$ and $\mathrm{N}_{3}$ const.

The determ in istic description of our process gives the wrong scaling of the num ber of nonfrozen nodes in the case of critical netw orks, but a correct criticality condition (3). W e are interested in the dynam icalbehavior of the netw orks in the critical phase and we w ill from now on study only netw orks $w$ th the param eters such that the criticality condition $13\left(1 \quad!_{1}\right)\left(1 \quad!_{2}\right)=0$ is full led.

Before we proceed by introducing the noise into the determ inistic equations, there is one $m$ ore piece of infor$m$ ation we can extract from the determ in istic description of the critical process that is going to help us later in determ ining the noise term. Introducing $n=N=N$ in $i$ and $n_{j}=N_{j}=N^{\text {in } i}$ for $j=f ; 1 ; 2 ; 3$, equations (2) simplify to (using the criticality condition)

$$
\begin{align*}
& \mathrm{n}_{3}=\mathrm{n}^{3} \\
& \mathrm{n}_{2}=\frac{1}{1!_{1}}\left(\mathrm{n}^{2} \mathrm{n}^{3}\right) \\
& \mathrm{n}_{1}=\mathrm{n} 2 \mathrm{n}^{2}+\mathrm{n}^{3} \\
& \mathrm{n}_{\mathrm{f}}=\frac{12!_{1}}{1 \mathrm{l}_{1}} \mathrm{n}^{2}+\frac{!_{1}}{1!_{1}} \quad \mathrm{n}^{3}: \tag{4}
\end{align*}
$$

This m eans that our stochastic process rem ains invariant (in the determ in istic approxim ation) when the initial
num ber of nodes in the containers and the tim e unit are all $m$ ultiplied by the sam $e$ factor. For $s m$ all $n$, the $m a-$ jority of nodes are in container $\mathrm{N}_{1}$, since $\mathrm{n}_{1}=\mathrm{n} \quad \mathrm{O}\left(\mathrm{n}^{2}\right)$. N ow, if we choose a su ciently large $N$ in $i, n$ reaches any given $s m$ all value while $N_{f} \quad n^{2} N$ in i is still large enough for a determ inistic description. We can therefore assum e that for su ciently large netw orks $\mathrm{N}_{\mathrm{f}}=\mathrm{N} \quad \mathrm{N}$ becom es sm all before the e ect of the noise becom es im portant. This assum ption will sim plify our calculations below.
IV. THEEFFECTOFFLUCTUATIONS

The num ber of nodes in container $N_{j}, j=1 ; 2 ; 3$, that choose a given frozen node as an input is Poisson distributed w ith a m ean $j N_{j}=N$ and a variance $j N{ }_{j}=N$. W e now assume that n is sm all at the m om ent where the noise becom es im portant, i.e., that the variance of the three noise term s is $\mathrm{N}_{1}=\mathrm{N}=\mathrm{n}_{1}=\mathrm{n}=1 \quad 2 \mathrm{n}+\mathrm{n}^{2}=$ $1 \mathrm{O}(\mathrm{n})$ and $2 \mathrm{~N}_{2}=\mathrm{N}=2 \mathrm{n}_{2}=\mathrm{n}=\frac{2}{1!!_{1}}\left(\mathrm{n} \quad \mathrm{n}^{2}\right)=\mathrm{O}(\mathrm{n})$ and $3 \mathrm{~N}_{3}=\mathrm{N}=3 \mathrm{n}^{2}=\mathrm{O}\left(\mathrm{n}^{2}\right)$. A 11 three noise term s occur in the equation for $N_{f}$, and since the rst term dom inates for $s m$ all $n$, we consider only this term in the equation for $N_{f}$. In the equations for $N_{1}$ and $N_{2}$, the noise term is $m$ uch sm aller than the num ber of nodes in these containers and can therefore be dropped.

Thee ect of the noise on the nal value of $N_{3}$ can be obtained by the follow ing consideration: as w ew illsee below, the $m$ ean nalvalue of $N_{3} w$ illbe a constant, which is independent of $\mathrm{N}{ }^{\text {in } \mathrm{i}}$. This m eans that each node that is initially in the container $\mathrm{N}_{3}$ has a probability of the order $1=\mathrm{N}$ in ${ }^{\text {i }}$ of never choosing a frozen input during the stochastic process, and this probability is independent for each node. From this follow s that the nal num ber $\mathrm{N}_{3}$ is P oisson distributed w ith a variance that is identical to the $m$ ean. $T$ his variance is nite in the $\lim$ it $N{ }^{\text {in }}{ }^{i}$ ! 1 and it does not a ect the nal value of $\mathrm{N}_{2}$ or $\mathrm{N}_{1}$. Since we have obtained the variance of the nal value of $N_{3}$ by this sim ple argum ent, we w ill not explicitly consider the noise term in the equation for $\mathrm{N}_{3}$.
W e therefore obtain the stochastic version ofequations (1), where we need to retain only the noise term in the equation for $N_{f}$ :

$$
\begin{align*}
& \mathrm{N}_{3}=\frac{3 \mathrm{~N}_{3}}{\mathrm{~N}} \\
& \mathrm{~N}_{2}=\frac{2 \mathrm{~N}_{2}}{\mathrm{~N}}+\frac{1}{\left(1!_{1}\right)} \frac{\mathrm{N}_{3}}{\mathrm{~N}} \\
& \mathrm{~N}_{\mathrm{f}}=1+\frac{\mathrm{N}_{1}}{\mathrm{~N}}+2!_{1} \frac{\mathrm{~N}_{2}}{\mathrm{~N}}+3 \frac{1}{\left(1!_{1}\right)} \frac{\mathrm{N}_{3}}{\mathrm{~N}} \\
& \mathrm{~N}_{1}=1: \tag{5}
\end{align*}
$$

The random variable has zero $m$ ean and unit variance. A s long as the $n_{j}$ change little during one tim e step, we can sum $m$ arize a large num ber $T$ of tim e steps into one e ective tim e step, w th the noise becom ing G aussian distributed $w$ ith zero $m$ ean and variance $T$. Exactly the sam e process w ould result ifw e sum $m$ arized $T$ tim e steps
of a process w ith G aussian noise of unit variance. For this reason, we can choose the random variable to be G aussian distributed w ith unit variance.

C om pared to the determ inistic case, the equations for $\mathrm{N}_{3}$ and $\mathrm{N}_{2}$ are unchanged. Inserting the solution for $\mathrm{N}_{3}$ and $\mathrm{N}_{2}$ into the equation for $\mathrm{N}_{\mathrm{f}}$, we obtain
$\frac{d N_{f}}{d N}=\frac{N_{f}}{N}+\frac{1 \quad 2!_{1}}{1} \frac{N}{N^{\text {in } i}}+2 \frac{!_{1}}{1 \quad!_{1}} \quad \frac{N}{N^{\text {in } i}}{ }^{2}+$
w ith the step size $\mathrm{dN}=1$ and $\mathrm{h}^{2} \mathrm{i}=1$. (In the continuum lim it $d N$ ! 0 the noise correlation becom es $\left.h(\mathbb{N})\left(\mathbb{N}^{0}\right) i=\left(\mathbb{N} N^{0}\right)\right)$. This is a Langevin-equation, and the corresponding Fokker $P$ lanck-equation is

$$
\begin{align*}
& \frac{@ P}{@ N}=\frac{@}{@ N_{f}} \frac{N_{f}}{N}+\frac{1}{1} \frac{2!_{1}}{!_{1}} \frac{N}{N^{\text {in } i}} \\
&+2 \frac{!_{1}}{1!_{1}} \quad \frac{N}{N^{\text {in } i}} \\
& 2^{\#}  \tag{7}\\
&+\frac{1}{2} \frac{\varrho^{2} \mathrm{P}}{\varrho N_{f}^{2}}:
\end{align*}
$$

Since we are investigating netw orks in the them odynam ic lim it, keeping only the leading term swill give a good approxim ation. T hus, we can neglect the last term in the expression under the partial derivative $w$ ith re-
 W e are left w th the Fokker $P$ lanck equation of the sam e type as the one already studied in [13], but w ith a di erent coe cient.

$$
\begin{equation*}
\frac{@ P}{@ N}=\frac{@}{@ N_{f}} \frac{N_{f}}{N}+\frac{N}{N{ }^{\text {in } i}} P+\frac{1}{2} \frac{@^{2} P}{\varrho N_{f}^{2}} ; \tag{8}
\end{equation*}
$$

where $=\left(\begin{array}{ll}1 & 2!\end{array}\right)=\left(\begin{array}{ll}1 & !_{1}\end{array}\right)$.
W e introduce the variables

$$
\begin{equation*}
x=\frac{N_{f}}{\mathrm{P}} \underset{\mathrm{~N}}{ } \text { and } y=\frac{N}{\left(\mathbb{N}^{\text {in } i}=\right)^{2=3}} \tag{9}
\end{equation*}
$$

and the function $f(x ; y)=\left(\mathbb{N}^{\text {in } i=}\right) P\left(N_{f} ; N\right) . T$ he free param eter willbe xed below by the condition that the probability distribution of the num ber ofnonfrozen nodes is norm alized. The Fokker-P lanck equation then becom es

$$
\begin{equation*}
y \frac{@ f}{@ y}+f+\frac{x}{2}+y^{3=2} \frac{@ f}{@ x}+\frac{1}{2} \frac{@^{2} f}{@ x^{2}}=0: \tag{10}
\end{equation*}
$$

Let $W \mathbb{N}$ ) denote the probability that $N$ nodes are left at the $m$ om ent where $N_{f}$ reaches the value zero. It is

$$
\mathrm{W}(\mathbb{N})=\mathrm{Z}_{1} \mathrm{P}\left(\mathbb{N}_{\mathrm{f}} ; \mathrm{N}\right) \mathrm{dN} \mathrm{~N}_{\mathrm{f}}{ }_{0}^{\mathrm{Z}_{1}} \mathrm{P}\left(\mathbb{N}_{\mathrm{f}} ; \mathrm{N} \quad 1\right) \mathrm{dN} \mathrm{~N}_{\mathrm{f}}
$$

C onsequently,

$$
\begin{aligned}
& W(\mathbb{N})=\frac{@}{@ N}_{0}^{Z_{1}} P\left(N_{f} ; N\right) d N_{f} \\
& =\left(\mathbb{N}^{\text {in } i}=\right) \quad{ }^{1=3} \frac{@}{@ y} \bar{y}^{Z} \int_{0}^{1} f(x ; y) d x \\
& \left.\mathbb{N}^{\text {in } i}=\right) \quad{ }^{1=3} G(y)
\end{aligned}
$$

with a scaling function $G(y) . W(N) m$ ust be a nom alized function,

$$
\left.\mathrm{Z}_{1} \mathrm{~W}(\mathbb{N}) \mathrm{dN}=\mathbb{N}^{\text {ini}}=\right) \quad{ }_{0}^{1=3+2=3} \mathrm{Z}_{1} \mathrm{G}(\mathrm{y}) \mathrm{dy}=1:
$$

This gives $=1=3$. This condition is independent of the param eters of the $m$ odel, and therefore $G(y)$ and $f(x ; y)$ are independent of them, too. N ow, we have

$$
W(\mathbb{N})=\left(\mathbb{N}^{\text {in } i}=\right)^{2=3} G(y)
$$

The $m$ ean num ber of nonfrozen nodes is

$$
N=Z_{0}^{Z_{1}} N W(\mathbb{N}) d N=\left(\mathbb{N}^{\text {ini }}=\right)^{2=3}{ }_{0}^{Z_{1}} G(y) y d y ;
$$

which is proportional to $(\mathbb{N} \text { in i })^{2=3}$.
The probability $\mathrm{W}_{2}\left(\mathbb{N}_{2}\right)$ that $\mathrm{N}_{2}$ nodes are left in container $\mathrm{N}_{2}$ at the m om ent where container F becom es em pty, is obtained from the relation

$$
N_{2}=\frac{1}{1 \quad!_{1}} \frac{N^{2}}{N^{\text {in } i}} \quad \frac{1}{1 \quad!_{1}} \frac{N^{3}}{\left(\mathbb{N}^{\text {in } i}\right)^{2}}:
$$

Since $W \mathbb{N}) d N=W_{2}\left(\mathbb{N}_{2}\right) d N_{2}$, we nd that the $m$ ean num ber of nodes left in container $\mathrm{N}_{2}$ is

$$
\begin{aligned}
& N_{2}=Z_{1}^{Z_{1}} N_{2} W_{2}\left(N_{2}\right) d N_{2}=Z_{1}^{Z_{1}} \mathrm{~N}_{2} W(N) d N \\
& =\frac{1}{()^{1=3}\left(1 \quad 2!_{1}\right)}\left(\mathbb{N}^{\text {in } i}\right)^{1=3}{ }_{0}^{1} y^{2} G(y) d y \\
& +\frac{1}{0}_{0}^{1} y^{2} G(y) d y \quad\left(\mathbb{N}^{\text {in } i}\right)^{1=3}:
\end{aligned}
$$

In the sam em anner we nd for the num ber of nodes left in container $\mathrm{N}_{3}$

$$
\begin{aligned}
& N_{3}=Z_{1}^{Z_{1}} N_{3} W_{3}\left(N_{3}\right) d N_{3}=Z_{1}^{Z_{1}} N_{3} W(\mathbb{N}) d N \\
& \left.=\frac{\left(1 \quad 2!_{1}\right)^{2}}{(1}!_{1}\right)^{2}{ }_{0}^{1} y^{3} G(y) d y \text { const: }
\end{aligned}
$$

Thus, we have show $n$ that the num ber of nonfrozen nodes scales w ith netw ork size $N^{\text {in } i}$ as $\left(\mathbb{N}^{\text {in }}\right)^{2=3}$, w ith $m$ ost of these nodes receiving only one input from other nonfrozen nodes. The num ber of nonfrozen nodes w ith two nonfrozen inputs scales as $\left(\mathbb{N}^{\text {in }}\right)^{1=3}$ and the num ber of nodes w th three such inputs is independent of the netw ork size.

> V. SPECIALPOINTSAND CANALYZING FUNCTIONS

For $!_{1}=1=2$, the second term in the Langevin Equation (6) is zero. In this case the next order term has to be taken into account since it is the leading one now. We w ill see that the $m$ echanism of creating the frozen core is
di erent for such system s , but in the end we w ill nd the sam e scaling behavior of the num ber of nonfrozen nodes.
$N$ ow we have to consider the $m$ odi ed Langevin equation

$$
\begin{equation*}
\frac{d N_{f}}{d N}=\frac{N_{f}}{N}+2(1 \quad) \quad{\frac{N}{N^{\text {ini }}}}^{2}+ \tag{11}
\end{equation*}
$$

and the corresponding Fokker-P lanck equation

$$
\begin{equation*}
\frac{@ P}{@ N}=\frac{@}{@ N_{f}} \frac{N_{f}}{N}+2(1 \quad) \quad \frac{N}{N^{\text {ini }}}{ }^{2} \quad P+\frac{1}{2} \frac{@^{2} P}{@ N_{f}^{2}}: \tag{12}
\end{equation*}
$$

W e again introduce new variables

$$
\begin{equation*}
x=\frac{N_{f}}{P} \frac{\left(N^{\text {in i }}\right)^{2}}{2(1 \quad)} \quad 4=5 \quad N^{2} \tag{13}
\end{equation*}
$$

and the function $f(x ; y)=\frac{\left(\mathbb{N}^{\text {in } i}\right)^{2}}{2(1)} \quad P\left(\mathbb{N}_{f} ; N\right)$. The Fokker $P$ lanck equation then becom es

$$
2 y \frac{@ f}{@ y}+f+\frac{x}{2}+y^{5=4} \frac{@ f}{@ x}+\frac{1}{2} \frac{@^{2} f}{@ x^{2}}=0:
$$

For the probability that N nodes are left when $\mathrm{N}_{\mathrm{f}}$ reaches zero we obtain

$$
W(\mathbb{N})=\frac{\left(\mathbb{N}^{\text {in })^{2}}\right)^{2}}{2(1 \quad)} \quad{ }^{2=5}(y)
$$

w ith a new scaling function $G$. W e have used the fact that this probability has to be nom alized, which gives $=1=5$.
U sing this result, we nd for the $m$ ean num ber of nonfrozen nodes

$$
\begin{align*}
N= & Z_{1} N W(\mathbb{N}) d N=\frac{1}{2} \frac{\left(\mathbb{N}^{\text {in } i}\right)^{2}}{2(1 \quad)} 0^{2=5 Z_{1}} \quad \underset{\left(N^{\text {in } i}\right)^{4=5}}{ }:
\end{align*}
$$

For the $m$ ean num ber of nonfrozen nodes left in containers $\mathrm{N}_{2}$ and $\mathrm{N}_{3}$ we nd

$$
\begin{align*}
& \mathrm{N}_{2}=\mathrm{Z}_{1} \mathrm{~N}_{2} \mathrm{~W}_{2}\left(\mathrm{~N}_{2}\right) \mathrm{dN} \mathrm{~N}_{2}=\mathrm{Z}_{1} \mathrm{~N}_{2} \mathrm{~W}(\mathbb{N}) \mathrm{dN} \\
& \begin{array}{c}
=\frac{\left.\mathbb{N}^{\text {in } i}\right)^{3=5}}{(2(1 \quad))^{4=5}}{ }^{Z_{1}} y^{1=2} G(y) d y \\
\\
\left.\frac{\left(\mathbb{N}^{\text {in } i}\right)^{2=5}}{\left(2(1 \quad)^{6=5}\right.}\right)_{1} y G(y) d y
\end{array} \\
& \left(N^{\text {in } i}\right)^{3=5} \tag{15}
\end{align*}
$$

and

$$
\begin{align*}
N_{3} & =Z_{1} \mathrm{~N}_{3} \mathrm{~W}_{3}\left(\mathrm{~N}_{3}\right) \mathrm{dN}_{3}=\mathrm{Z}_{1} \mathrm{~N}_{3} \mathrm{~W}(\mathbb{N}) \mathrm{dN} \\
= & \frac{\left.-\mathbb{N}^{\text {in } \mathrm{i}}\right)^{2=5}}{2} \frac{\mathrm{Z}_{1}}{(2(1))^{6=5}} 0 \\
& \left.\mathrm{~N}^{\text {in } \mathrm{i}}\right)^{2=5}: \tag{16}
\end{align*}
$$

W e see that the num ber of nodes which becom e frozen due to the in uence of the constant functions is sm aller than in the case of other critical netw orks. W hen we look at the param eters for these netw orksm ore closely, we see that these networks are e ectively canalyzing with two inputs per node. The probability that a node w th two inputs is going to freeze during one tim e step is $!_{1}=1=2$ and this $m$ eans that the netw ork has B oolean functions such that nodes $w$ th two nonfrozen inputs e ectively belong to the $\mathrm{C}_{1}$ or $\mathrm{C}_{2}$ class of $B$ oolean functions $w$ th two variables, i.e., canalyzing functions. T he class $\mathrm{C}_{1}$ contains those functions that depend only on one of the tw o variables, but not on the other one. $T$ he class $C_{2}$ contains the rem aining canalyzing functions, where one state of each input xes the output. It has been shown in [14] that in $K=2$ netw orks $w$ ith only this type of functions another $m$ echanism of creating the frozen core arises. The only condition for this is that the num ber of nodes from class $\mathrm{C}_{2}$ is large enough. W e will show that it is exactly what happens in the netw orkswe are analyzing now. The num ber ofnonfrozen nodes $w$ th two inputs and canalyzing $\mathrm{C}_{2}$ functions is here large enough to allow for the creation of the self-fieezing loops that are going to increase the num ber of frozen nodes and thus change the scaling of the nonfrozen nodes from $\left(\mathbb{N}^{\text {in } i}\right)^{4=5}$ to $\left(\mathbb{N}{ }^{\text {in } i}\right)^{2=3}$.

## VI. CREATING SELFFREEZING LOOPSAND THEIR EFFECT

W e are now considering a reduced netw ork consisting of those nodes that are not frozen through the in uence of the nodes w ith constant functions. The size of this netw ork is $N,\left(\mathbb{N}^{\text {in } i}\right)^{4=5}$, m ost of the nodes have one nonfrozen input, $\mathrm{N}_{2}{ }^{\prime}\left(\mathbb{N}^{\text {ini }}\right)^{3=5}$ have two, and $\mathrm{N}_{3}{ }^{\prime}$ $\left(\mathbb{N}^{\text {in } i}\right)^{2=5}$ have three nonfrozen inputs. $N$ odes with two nonfrozen inputs have a probability to freeze $!_{1}=1=2$ and as such $e$ ectively have canalyzing $B$ oolean functions of two argum ents, belonging to $\mathrm{C}_{1}$ or $\mathrm{C}_{2}$ class. So, the num ber of nodes $w$ ith two nonfrozen inputs that belong to the $\mathrm{C}_{2}$ class has to be' $\left(\mathbb{N}^{\text {in } i}\right)^{3=5}$ as it is the fraction of all nonfrozen nodes w th two inputs.

Let us now assume that there exist groups of nodes that $x$ each other's value and do not respond to changes in nodes outside this group. The simplest exam ple of such a group is a loop of $C_{2}$ nodes w here each node canalyzes (xes) the state of its successor once it settles on its m a jority bit (the one occurring 3 tim es in its update function table). These loops, introduced in [14], are called self-freezing loops. T hey can also contain chains of nodes $w$ ith one nonfrozen input or w ith two nonfrozen inputs and a $\mathrm{C}_{1}$ function betw een $\mathrm{C}_{2}$ nodes. If a chain between tw $\circ \mathrm{C}_{2}$ nodes as a whole inverts the state of the rst $\mathrm{C}_{2}$ node, the inverted $m$ ajority bit of the rst $C_{2}$ node has to canalyze the second $\mathrm{C}_{2}$ node. T he only e ect of nodes w ith $\mathrm{C}_{1}$ functions and those w th one nonfrozen input in such loops is to delay the signalpropagation betw een tw o adjacent $\mathrm{C}_{2}$ nodes. $T$ he procedure of nding self-freezing
loops is explained in details in [14]. The num ber of nodes on self-freezing loops is there found by $m$ apping the problem of nding a self-freezing loop in a $\mathrm{C}_{2}$ netw ork onto the problem of nding the relevant nodes sitting on relevant loops in a critical netw ork that contains no canalyzing functions at all, but only reversible (where the output is changed whenever one of the inputs is changed) and constant functions. U sing results for these reversible networks obtained in [13] it was found that the num ber of nodes on self freezing loops scales as $N^{1=3}$ where $N$ is the num ber of $\mathrm{C}_{2}$ nodes.

O bviously, nodes depending on or canalyzed by the frozen nodes of the self-freezing loops freeze also, and such nodesm ay lead to the freezing of further nodes, etc. W e can introduce a dynam ical process in order to determ ine the total num ber of nodes that becom efrozen because of the self-freezing loops. This process is alm ost the same as the one we have used for identifying the in uence of the constant functions on the netw orks dynam ics. W e again have four containers where the nodes left after determ ining the in uence of the nodes w ith constant fiunctions are placed. Initially nodes found to be on the self-freezing loops are going to be $m$ oved from the container with nodes w ith two inputs, $\mathrm{N}_{2}$, to the container F . Thus the initial num ber of nodes in the containers is going to be $N_{f}^{0}=\left(\left(\mathbb{N}^{\text {in } i}\right)^{3=5}\right)^{1=3}=\left(\mathbb{N}^{\text {in } i}\right)^{1=5}$, $N_{2}^{0}=\left(\mathbb{N}^{\text {in } i}\right)^{3=5} \quad N_{f}^{0},\left(\mathbb{N}^{\text {in } i}\right)^{3=5}$ and $N_{3}^{0}=\left(\mathbb{N}^{\text {in i }}\right)^{2=5}$, and the total num ber of nodes is $N^{0}=\left(N^{\text {in } i}\right)^{4=5}$. N ow we run the sam e dynam ical process as before determ ining in uence of the nodes from the frozen loops on the rest of this reduced netw ork one by one and then rem oving them from the system. At the end of th is process we w ill again have nodes in the container $\mathrm{N}_{2}$. They can now $m$ ake new self-freezing loops $m$ ade of $C_{2}$ nodes $w$ ith the chains of nodes w ith one nonfrozen input betw een them. $W$ e can then again $m$ ove $N_{2}^{1=3}$ nodes that are on the new self-freezing loops to the container $F$ and run the sam $e$ process again. W e can even take over the values of $\mathrm{N}_{1}, \mathrm{~N}_{2}$ and $N_{3}$ and $N$ at the end of the rst process, since $N_{2}{ }^{1=3}$ frozen nodes $m$ oved from container $\mathrm{N}_{2}$ are negligible in com parison to $\mathrm{N}_{2}$. These processes can be repeated as long as the num ber of nodes of type $C_{2}$ is large enough to allow for the creation of self-freezing loops. T he equations for the change of $N_{3}$ and $N_{2}$ nodes

$$
\begin{align*}
& N_{3}=\frac{3 N_{3}}{N} \\
& N_{2}=\frac{2 N_{2}}{N}+\frac{2}{N} \frac{N_{3}}{N} \tag{17}
\end{align*}
$$

apply together to all the successive processes of freezing the netw ork through the in uence of nodes of the self-freezing loops. Between each two of them the new self-freezing loops have been found and $m$ oved from the container with $\mathrm{N}_{2}$ nodes allow ing for the new process to start. The equation for $N$ is $N=1$, as before. The solution of these equations is obtained by going to differential equations for $d N_{2}=d N$ and $d N{ }_{3}=d N$. U sing the
values of $N, N_{2}$ and $N_{3}$, found in Equations (14), (15) and (16), as initial values of the variables, these di erential equations have the solution

$$
\begin{align*}
& N_{3}=\frac{N_{3}^{0}}{\left(\mathbb{N}^{0}\right)^{3}} N^{3}  \tag{18}\\
& N_{2}=\frac{N_{2}^{0}+(2=) N_{3}^{0}}{\left(\mathbb{N}^{0}\right)^{2}} N^{2} \quad \frac{2 N_{3}^{0}}{\left(N^{0}\right)^{3}} N^{3}: \tag{19}
\end{align*}
$$

The num ber of rem aining $N_{1}$ nodes increases in the second process, the num ber of $\mathrm{C}_{2}$ (those in container $\mathrm{N}_{2}$ ) nodes decreases, thus leading to an increasing weight of $\mathrm{N}_{1}$ nodes in the nonfrozen netw ork.

The repeated process of identifying generalized selffreezing loops and the nodes frozen by them breaks dow $n$ when the rem aining nonfrozen nodes cannot be considered as an e ective $\mathrm{C}_{2}$ netw ork any m ore. $T$ his happens when in the process of creating self-freezing loops the probability that a $\mathrm{C}_{2}$ node is going to be attached to the end of the chain of nodes w ith one nonfrozen input (thusm aking closing self-freezing loop possible) becom es of the sam e order of $m$ agnitude as the probability that this chain becom es a loop. Since the $m$ ean size of the loops $\beta$ f nodes $w$ th one input is found to be of the order of $\overline{\mathrm{N}}$ [15] the assemply of self-freezing loop becom es im probable when $\mathrm{N}_{2} \quad \mathrm{P} \frac{\mathrm{N}}{\mathrm{N}}$.
$T$ his condition gives to leading order

$$
\begin{equation*}
\frac{\left(\mathbb{N}^{0}\right)^{2}}{\mathrm{~N}_{2}^{0}} \quad \mathrm{~N}^{3=2} \tag{20}
\end{equation*}
$$

or $N \quad\left(N^{\text {in }}\right)^{2=3}$. We again have the sam e scaling of the number of nonfrozen nodes $w$ th the netw ork size. $T$ he scaling of the number of nonfrozen nodes $w$ th two and three nonfrozen inputs $w$ ith the netw ork size we nd from (19) and (18) to be $N_{2} \quad\left(\mathbb{N}^{\text {in } i}\right)^{1=3}$ and $N_{3}$ const. $T$ his is the sam e scaling we have for the case of all other critical netw orks investigated until now.

W hen nding the num ber of nodes on the self-freezing loops and de ning our second process we assum ed that there the in uence of the nodes $w$ ith three nonfrozen inputs per node is negligible. W e can check if our assum ption was justi ed. In the beginning of this process the num ber of nodes w ith three inputs was $N_{3}^{0}{ }^{\prime}\left(\mathbb{N}^{\text {in } i}\right)^{2=5}$. $T$ he num ber of nodes that are initially on self-freezing loops is $\left(\mathbb{N}_{2}^{0}\right)^{1=3}=\left(\mathbb{N}^{\text {in } \mathrm{i}}\right)^{1=5}$. Them ean num ber ofnodes w ith three inputs on the self-freezing loops is then

$$
\left(\mathrm{N}_{2}^{0}\right)^{1=3} \frac{\mathrm{~N}_{3}^{0}}{\mathrm{~N}_{2}^{0}}=\text { const : }
$$

In the lim it of large netw ork size, only a few (if any) self-fireezing loops are destroyed by nodes w th three nonfrozen inputs, and this does not change the scaling behavior of the num ber of nodes on self-freezing loops.
VII. NETW ORKSW ITHOUT CONSTANT FUNCTIONS
A. C ase $!_{1}=1=2,!_{2}=1=3$

Until now, we have assum ed that the netw ork has nodes w ith constant functions. In this section, we consider netw orks w ithout constant functions, i.e., w ith = 1. T he criticality condition (3) then becom es

$$
3\left(1 \quad!_{1}\right)(1 \quad!2)=1:
$$

A lthough the criticality condition w as derived under the assum ption that the netw ork has a nonvanishing proportion of frozen nodes (i.e., that < 1), it can be extended to $=1$, since it is valid for any arbitrarily close to 1. Furtherm ore, decreasing slightly for xed ! 1 and $!2 \mathrm{~m}$ oves the system to the frozen phase, indicating that a system satisfying the criticality condition with $=1$ is at the boundary of the frozen phase. As we w ill see, the value of the param eters in the critical netw orks $w$ ithout constant functions w e are considering here is allow ing the form ation of the self-freezing loops and leads to the frozen core of the sam e size as for all the other critical netw orks. C analyzing netw orks and threshold netw orks are exam ples of this category of netw orks, and they are considered im portant for biological applications.

T he procedure ofcreating self-freezing loops in the case ofnetw orks w th nodes w ith tw o nonfrozen inputs w as introduced and explained in details in [14]. It is the sam e procedure we have used in the previous section. U sing a sim ilar line of argum ents we can explain the assem bly of the self-freezing loops for the netw orks w ith three inputs per node determ ined w ith param eters being $!_{1}=1=2$, $!_{2}=1=3$ and $=1$. In this case there is a m apping of the problem of nding the nodes on the self-freezing loops in this netw ork onto the problem of nding the relevant nodes on relevant loops in critical netw ork w ith three inputs per node and only reversible and constant functions, i.e., $w$ ith $!_{1}=!_{2}=0$ and $=1=3$. Self-freezing loops are found by starting $w$ ith a node and keeping track of the connection to those inputs that are able to canalyze this node ifthey are canalyzed them selves. This procedure is iterated for these input nodes etc., until a loop is form ed or until it has to stop because no canalyzing inputs are found. Sim ilarly, relevant loops in a criticalnetw ork w ith $!_{1}=!_{2}=0$ are found by starting $w$ ith a node and keeping track of the connection to those inputs that do not have a constant function. This procedure is iterated for the nonfrozen inputs etc., until a loop is form ed or until it has to stop because no nonfrozen inputs are found. In both cases, a connection to an input is $m$ ade $w$ ith probability $1 / 3$, show ing that the tw o processes can be m apped on each other. As we will show in section 9 below, in critical netw orks w ith three inputs per node and nonzero fraction of frozen nodes the num ber of relevant nodes on relevant loops scales as $\left(\mathbb{N}^{\text {ini}}\right)^{1=3}$. T herefore, we conclude that in the netw ork w ith $!_{1}=!_{2}=0$, the num ber of nodes on self-freezing loops scales also as $\left(\mathbb{N}^{\text {ini }}\right)^{1=3}$.

W e can now proceed just as in the previous section, but w ith $=1$ and $\mathrm{N}_{j}^{0}=\mathrm{N}_{\mathrm{j}}^{\text {ini }}$. We continue m aking selffreezing loops and detprm ining which nodes are frozen by them, until $\mathrm{N}_{2} \quad \mathrm{~N}$. Inserting this condition in Equation (19), we nd to leading order

$$
2 \frac{N^{3=2}}{N^{\text {in i }}}=1
$$

leading again to $N \quad\left(N^{\text {in } i}\right)^{2=3}$.
B. G eneral case

N ow, let ustum to the case $=1 \mathrm{w}$ ith $!_{1}<1=2$. ( T he situation $!_{1}>1=2$ is not possible for nonfrozen B oolean functions w ith two inputs.) T he probability that a node we don't know anything about freezes when connected to a frozen node is now $!_{2}>1=3$. Every node has three inputs and this frozen node could be any of them. This $m$ eans that on an average a node can be frozen by m ore than one input, and the self-freezing com ponents we look for in the netw ork here consist of at least as m any nodes as those in the previous subsection. H ow ever, we do not need to know the exact num ber of frozen nodes in these com ponents. W e w ill build only one self-freezing loop and move its $\left(N^{\text {in }}\right)^{1=3}$ nodes to the container $F$. Then we start the calculation of Section II by setting $=1$ $\left(\mathbb{N}^{\text {in } i}\right)^{2=3}$. Since $!_{1}<1=2$, the leading-order term $s$ of the calculation perform ed in Section II are retained in this case, and we can take over all the $m$ ain results of that section. In particular, it follow s that a single selffreezing loop is su cient to generate the entire frozen core, and we do not need to identify other self-freezing loops. A s before, the num ber of nonfrozen nodes scales as $\left(\mathbb{N}^{\text {in } i}\right)^{2=3}$.
VIII. GENERALIZATION TO LARGER K

T he process introduced in Section II can easily be generalized to netw orksw ith $K>3$.W e rst consider again the case < 1. For netw ork w ith $K$ inputs we de ne a set of param eters and ! i w ith i 2 [1;K 1]. is again fraction of the nonfrozen nodes and $!_{i}$ is the probability that a nonfrozen node that has $\mathrm{K} \quad i$ inputs from frozen nodes freezes w hen receiving another frozen input in our process. These $K$ param eters are going to de ne com pletely the class of netw orks we observe in the process. U sing the determ inistic description of the process analogous to the one described in Section IIT we nd the criticality condition for netw orks w th any K :

$$
\begin{equation*}
K\left(1 \quad!_{1}\right)\left(1 \quad!_{2}\right) \quad\left(1_{K}!_{1}\right)=1: \tag{21}
\end{equation*}
$$

Introduction of noise in the process gives the Langevin equation

$$
\begin{equation*}
\frac{d N_{f}}{d N}=\frac{N_{f}}{N}+\mathrm{X}_{i=1}^{1} f_{i}\left(!_{1} ;::: ;!_{i}\right) \frac{N^{i n i}}{N^{i}}+ \tag{22}
\end{equation*}
$$

where the $f_{i}\left(!_{1} ;::: ;!_{i}\right)$ are functions of the param eters of the system obtained from the stochastic process $T$ hey satisfy $f_{i}\left(!_{1} ;::: ;!_{i}\right)=0$ when $!_{j}=1=(j+1)$ for all j 2 [1;i]. We see that in this generalLangevin equation the leading term in N is the same as in Equation (6). $T$ herefore we nd that in the them odynam ic lim it the num ber of nonfrozen nodes scales in critical netw orks as $\left(N^{\text {in }}\right)^{2=3} \mathrm{w}$ ith the netw ork size.

Just like in the $\mathrm{K}=3$ netw orks, param eter values can be such that one or $m$ ore of the leading term $s$ in the Langevin equation vanish. These special points in the param eter space describe netw orks where the Boolean functions are such that the nodes left nonfrozen after determ ining the in uence of the frozen nodes in our process can additionally generate self-freezing loops. Their in uence on the rest of the netw ork has to be determ ined by generalization of the process introduced in Section VI. $T$ he num ber of classes of special points $w$ ill increase w ith K , leading to a hierarchy of special points. For each K , there are $K \quad 3$ classes of points in param eter space that are equivalent to the specialpoints ofnetw orksw ith K 1 inputs per node (that is they have the sam e leading term in the Langevin equation), and one new class of special points where only the last term in the Langevin equation (22) is nonzero. Furthem ore, there is the case $=1$. A s an ilhustration, in the case $K=4$ there are tw o classes of special points for $<1$. O ne of them has $!_{1}=1=2$. In this case, the in uence of the frozen nodes will lead to $\left(\mathbb{N}^{\text {in }}\right)^{4=5}$ nonfrozen nodes. Boolean functions of the nodes w ith 2 nonfrozen inputs and the num ber of them left after the rst process are such that self-fireezing loops are $m$ ade and their in uence will again give $\left(\mathbb{N}^{\text {in } i}\right)^{2=3}$ as the num ber ofnonfrozen nodes in the netw ork. This case can obviously be reduced to the $\mathrm{K}=3$ network. The other class of special points is obtained when the param eters of the netw ork are $!_{1}=1=2$ and $!_{2}=1=3$. In this case, $\left(\mathbb{N}{ }^{\text {in } i}\right)^{6=7}$ nodes w ill be left nonfrozen after deter$m$ ining the in uence of the frozen nodes. O ne can easily show that the creation of self-freezing loops is possible and that their in uence leads to a num ber of nonfrozen nodes that scales as $\left(\mathbb{N}^{\text {in } i}\right)^{2=3}$ w ith the netw ork size.

For general values of K, the K 2 classes of special points $w$ ith $<1$ are given by the condition $!_{j}=$ $1=(j+1)$ for all $j 2$ [1;i] where $i$ takes for every class one of the values from the interval $[1 ; K \quad 2]$. $T$ hism eans that $f_{1}=0 ;::: ; f_{i}=0$ in the Langevin equation (22) and the term $f_{i+1}\left(!_{1} ;::: ;!!_{i+1}\right)\left(\mathbb{N}=N^{\text {in })^{i+1}}\right.$ is the leading one. The nodes left nonfrozen after determ ining the in uence of the nodes $w$ ith constant functions scale $w$ ith the netw ork size as $\left(\mathbb{N}^{\text {in }}\right)^{(2 i+2)=(2 i+3)}$. The num bers and B oolean functions of the nodes with $k 2$ [2;i+1]nonfrozen inputs are such that they allow for the creation of the self-freezing loops, and their in uence will for each of these special points, ie., for each i $2[1 ; \mathrm{K} \quad 2]$, reduce the num ber of nonfrozen nodes to $\left(N^{\text {in } i}\right)^{2=3}$.

For netw orks w ithout constant functions (that is with
$=1$ ) the frozen core arises only because of the creation ofself-freezing loops and theire ect on the netw ork.

Just like for all other param eter values, there is straightforw ard generalization of the analysis perform ed for this type of netw orks in the case when $\mathrm{K}=3$ in Section $V$ II. In the case when $!_{i}=1=(i+1)$ for alli2 $[1 ; K \quad 1]$ there exists again a mapping of the self-freezing loops on the relevant loops of a K criticalnetw ork w ith only reversible and nonfrozen functions, from which it follows that the num ber of nodes that are initially on self-freezing loops scales as $\left(\mathbb{N}^{\text {in }}\right)^{1=3}$. The process described in Section V I can then be generalized to these netw orks. For any other choice of param eters satisfying the criticality condition (21) for $=1$, self-freezing loops can also be form ed, and after m oving only one of them in the container with frozen nodes wew ill have the sam e process as for the one of the classes of criticalnetw orksw ith $<1$ that were already studied. Scaling of the num ber of nonfrozen nodes in the critical netw orks w thout frozen nodes and any xed num ber of inputs $w$ ill be the sam e as in all other critical netw orks.

Let us end this section by noting that there is another class of special points when the Boolean functions are chosen such that each of them responds only to one of the $K$ inputs. In this case, the netw ork is e ectively a $K=1$ netw ork, since for each node those $K \quad 1$ inputs to which the node does not respond, can be cut o. In the calculations of the previous sections we have alw ays assum ed that a nonvanishing proportion of functions is not of this type.

## IX. RELEVANTNODESAND THENUMBER AND LENGTH OFATTRACTORS

Relevant nodes are the nodes whose state is not constant and that control at least one relevant node. T hese nodes determ ine com pletely the num ber and period of attractors. In the previous sections, we have shown that the num ber of nonfrozen nodes scales as $\left(\mathbb{N}^{\text {in }}\right)^{2=3}$ for any criticalnetw ork. W e have also seen that am ong them there are only $\left(\mathbb{N}{ }^{\text {in } i}\right)^{1=3}$ nodes having tw o nonfrozen inputs, and that the num ber of nonfrozen nodes $w$ th $m$ ore than two nonfrozen inputs vanishes in the therm odynam ic lim it. The nonfrozen nodes can now be connected to a netw ork. This is a reduced netw ork, where all frozen nodes have been cut o. In [13], we de ned a stochastic process for the form ation of this reduced netw ork and the identi cation of the relevant nodes for criticalK $=2$ netw orks. The relevant nodes are determ ined by rem oving iteratively nodes that are not relevant because they in uence only frozen and irrelevant nodes. The num ber of relevant nodes was found to scale as $\left(\mathbb{N}^{\text {ini}}\right)^{1=3}$, and the scaling function characterizing their probability distribution depends on the param eters of the $m$ odel.
$T$ he scaling of the num ber of nonfrozen nodes as well as the scaling of the number of nonfrozen nodes with two nonfrozen inputs as function of the netw ork size is the sam e for every critical netw ork, as we have shown in this paper. Since the fraction of nodes $w$ th $m$ ore
than two nonfrozen inputs is vanishing in the therm odynam ic lim it, the netw ork of nonfrozen nodes, which is the starting point for the process of determ ining the relevant nodes, is the same as in the $\mathrm{K}=2$ case. So, we can conclude that the results for the scaling of the num ber of relevant nodes found in [13] for the $K=2$ critical netw orks are valid for any critical netw ork. T he num ber of relevant nodes in critical netw orks scales as $\left(\mathbb{N}^{\text {in }}\right)^{1=3} \mathrm{w}$ ith the netw ork size. A $m$ ong them are a constant num ber of relevant nodes $w$ ith tw o relevant inputs and a vanishing num ber of relevant nodes $w$ ith $m$ ore than tw o relevant inputs in the lim it $N{ }^{\text {in } i}!1$. If only these nodes and the links betw een them are considered, they form loops w ith possibly additional links and chains of relevant nodes w ithin and betw een loops.

It follow s that all critical netw orks w ith $\mathrm{K}>1$ show the sam e scaling behavior. T he only exception is the case $\mathrm{K}=1$, which is di erent because there is no frozen core.

As we have shown in [13], we can derive properties of attractors from the results for the relevant nodes. In particular, we can take over the result of [13] that all relevant com ponents apart from a nite num ber are sim ple loops, and that the $m$ ean num ber and length of attractors increases faster than any pow er law w ith the netw ork size.

## X . CONCLUSION S

In this paper, we have considered the lim it of large netw ork size, and we have found the scaling behavior of the num ber of nonfrozen nodes, of the num ber of nonfrozen nodes $w$ ith $m$ ore than one nonfrozen input, of the num ber of relevant nodes, and of the num ber of relevant nodes $w$ th $m$ ore than one relevant input in a generalclass of critical random Boolean netw orks w ith xed num ber of inputs per node. The $m$ ean values of these quantities scale w ith netw ork size $N{ }^{\text {in i }}$ as a power law in $N{ }^{\text {in i }}$, w th the exponents being the sam e for any critical network. Nom atter what the distribution of the B oolean functions is and how $m$ any inputs per node the critical netw ork has, num ber of nonfrozen nodes scales w ith the netw ork size as $\left(\mathbb{N}^{\text {in }}\right)^{2=3}$, the num ber of nonfrozen nodes w th two nonfrozen inputs scales as $\left(\mathbb{N}^{\text {in }}\right)^{1=3}$, the exponent for the num ber of nonfrozen nodes w ith three nonfrozen inputs is zero, and it is $n=3$ for the num ber of nonfrozen nodes w th $\mathrm{n}+3$ nonfrozen inputs. The num ber of relevant nodes scales alw ays as $\left(\mathbb{N}^{\text {in } i}\right)^{1=3}$, w ith a constant num ber of them having two inputs and a vanishing proportion having $m$ ore than two.

It follow $s$ that all critical random B oolean netw orks w ith $K>1$ belong to the sam e class of system s . Changing the weights of the di erent Boolean functions (for instance by choosing threshold netw orks or canalyzing netw orks) or changing the num ber of inputs per node (which m ight m ake the m odelm ore relevant forbiological applications) will not change the scaling of the num ber of nonfrozen and relevant nodes w ith the size of the net-
work, and it willnot change the fact that the num ber and length of attractors increases faster than any pow er law w ith the netw ork size, as long as the netw ork is critical. U sing a di erent m ethod, Sam uelsson and Socolar have recently also found that the num ber of nonfrozen nodes scales in the sam e way for all $K>1$ critical netw orks [16].

From the calculations perform ed in this paper it can be concluded that the results are also valid for netw orks that have nodesw ith di erent values of $K$. If $\mathrm{K}_{\mathrm{m}}$ ax is the largest num ber of inputs occuring in the netw ork, we can set $K=K_{m}$ ax , and we can view nodes $w$ ith less inputs as nodes $w$ ith $K_{m}$ ax inputs, but $w$ ith a function that does not depend on all of its inputs. In contrast, our results cannot be generalized to netw orks w ith a broad distribution of the num ber of outputs. The $m$ ethod em ployed in this paper is based on a P oissonian distribution of the num ber of outputs, and is m ost likely valid also for other distributions as long as the second $m$ om ent of the num ber of outputs is nite. This can for instance be concluded from the analogy betw een the propagation of activity in a B oolean netw ork and percolation on a directed graph, for $w$ hich $m$ any results are know $n$ [17].

The nding that the num ber and length of attractors in criticalB oolean netw orks increases supenpolynom ially w ith netw ork size is detrim ental to the hypothesis that these netw orks are $m$ odels of gene regulation netw orks, where only a lim ited num ber ofdynam ic pathw ays should exist. H ow ever, by considering asynchronous update instead of parallel update and by requiring that dynam ics should be robust with respect to uctuations in the update sequence, the num ber of attractors reduces to a pow er law in system size, which ism ore realistic than the superpolynom ial grow th [18, 19]. T he $m$ ethod presented in this paper is independent of the updating schem e, and the scaling of the num ber ofnonfrozen and relevant nodes is therefore sam e for asynchronous update as for parallel update. The relevant com ponents are consequently also the sam e. W ith the insights obtained in the present paper, we can immediately apply the results for asynchronous update in $\mathrm{K}=2$ critical netw orks to critical netw orks w ith larger values of $K$, and we can conclude that the num ber of attractors in critical netw orks w ith asynchronous update increases as a pow er law of the system size.

F inally, let us consider netw orks w here the connections betw een nodes are not $m$ ade at random, but that show som e degree of clustering. Such netw orks have a nite proportion of nodes that have correlated inputs and that can therefore becom e frozen, e.g., because their inputs are alw ays in the sam e state. In contrast, the random ly w ired netw orks considered in the present paper have only a lim ited and sm all num ber of nodes w ith correlated inputs even in the therm odynam ic lim it of in nite netw ork size. For sm all-w orld netw orks, which have a high degree of clustering, ourm ethod for determ ining the frozen core is not valid, because it is based on the assum ption that nodes choose their inputs independently from each
other. Sm all-w orld netw orks need therefore a separate analytical treatm ent, which has not been done so far.
