Quantum critical point in the Kondo (Heisenberg model on the honeycom b lattice

### Saeed Saremi and Patrick A. Lee

D epartm ent of P hysics, M assachusetts Institute of Technology, C am bridge, M assachusetts 02139 (D ated: O ctobor 10, 2006)

We study the Kondo {Heisenberg model on the honeycomb lattice at half-lling. Due to the vanishing of the density of states at the ferm i level, the Kondo insulator disappears at a nite Kondo coupling even in the absence of the Heisenberg exchange. We adopt a large-N formulation of this model and use the renormalization group machinery to study systematically the second order phase transition of the Kondo insulator (KI) to the algebraic spin liquid (ASL). We note that neither phase breaks any physical symmetry, so that the transition is not described by the standard Ginzburg-Landau-Wilson critical point. We note a stable Lorentz-invariant xed point that controls this second order phase transition. We calculate the exponent of the diverging length scale near the transition. The quasi-particle weight of the conduction electron vanishes at this KI{ASL xed point, indicating non-Ferm i liquid behavior. The algebraic decay exponent of the staggered spin correlation is calculated at the xed point and in the ASL phase. We note a jump in this exponent at the transition point.

#### I. IN TRODUCTION

The interplay between charge and spin degrees of freedom has been a focus of research in complex materials such as cuprates and heavy-ferm ions. The clearest example of this interplay is the quantum critical point seen in many heavy-ferm ion materials. At zero temperature, the heavy Fermi liquid (HFL) phase disappears exactly at a point where the anti-ferrom agnetic (AF) magnetic ordering grows. Non-Fermi liquid behaviors are seen in the quantum critical region, i.e. the V-shaped region above this critical point. The theoretical understanding of why these two seem ingly dierent phases, i.e. AF ordered and heavy fermi liquid, should collapse at one point and a clear understanding of the non-Fermi liquid behaviors in the quantum critical region are poor at the moment.

It is by now understood that the spin density wave approach to understand the quantum critical point in heavy-ferm ions, known as the Moriya{Hertz{Millistheory², only accounts for small deviations from Fermi liquid theory. New theoretical approaches for understanding the quantum critical heavy-fermions are needed.

In an attempt to nd an alternative for the Moriya{ Hertz{Millistheory, Senthilet al. proposed recently that the AF {HFL transition m ight be controlled by an unstable spin liquid xed point.3,4 This picture is very similar to the Decon ned quantum critical point in the context of the second order phase transition between Neel and valence bond solid (VBS) ground states. In that case the transition to VBS happens due to the existence of an unstable spin liquid on the magnetically disordered side of the critical point. Decon ned quantum critical points open up the possibility of second order phase transitions between \unrelated" phases like AF and HFL. It also has the advantage of giving a plausible scenario for the non-Ferm i liquid behavior seen in experim ents in heavy ferm ion materials. This view has had some successes in explaining some of the experimental observations.6,7 In this paper, we further explore this point of view.

In search for a microscopic model that provides this type of quantum critical point, we study the K ondo { Heisenberg model on the honeycom b lattice at half-lling. The heavy ferm ion quantum critical point in this model is simplied. It corresponds to a point, where both charge gap and spin gap vanishes. This model is given by the following Hamiltonian ( $J_K > 0$ ;  $J_H > 0$ ):

where i and j live on the honeycomb lattice sites and a is the spin index:  $f"; \sharp g.$  The  $s_i$  and  $S_i$  denote the conduction electron spin and the localized spin at the site i respectively. What makes the honeycomb lattice very interesting to study is the fact that the K ondo gap vanishes at a nite coupling constant even as  $J_H$ ! 0. This is due to the fact that, in contrast to the square lattice, the density of states of the conduction electrons vanishes at the Ferm i level.  $^8$ 

The Kondo (Heisenberg model on the honeycomb lattice at half-lling is also interesting, because it can be studied by quantum Monte Carlo without the ferm ion sign problem .9,10 The present paper can be considered a prelude to such a study. In this connection we mention the quantum M onte Carlo study of the K ondo lattice m odel  $(J_H = 0)$  on the square lattice by A ssaad. 10 He found a quantum phase transition of the AF ordered ground state to a disordered one caused by the Kondo exchange. The quasi-particle gap however did not vanish at the transition point,  $^{26}$  i.e. the magnetic transition happened inside the KI phase. This made the transition a magnetic transition belonging to the O (3) nonlinear sigm a model universality class. Note that the nested Ferm i line of the tight-binding band provides the instability towards AF at (; ) even in the absence of the H eisenberg exchange  $J_H$  . In contrast the honeycom b lattice tight binding band has Ferm i points in the corner of the Brillouin zone called the Dirac points. This causes the nesting to be extremely weak as compared to the per-

FIG. 1: A scenario for the zero temperature phase diagram of the K ondo {H eisenberg H am iltonian on the honeycom b lattice at half-lling (given by H am iltonian Eq. (1)] as a function of  $J_K \ \ (t=1)$  for a su ciently small  $J_H$ . In contrast to the same model on a square lattice, K ondo gap denoted schem atically by the dotted-dashed line vanishes at a nite coupling constant  $J_{1K}^{\rm cr}$ . The weak nesting of the D irac nodes of the honeycom b lattice makes the K I transition to a spin liquid ground state plausible.

fectly nested lines of the Ferm i line in the square lattice. Next we consider di erent scenarios for the ground state phase diagram of our model, where we consider varying  $J_K \ \ \, (t=1)$ , keeping  $J_H$  to be small. In the lim it  $J_K \ \ \, J_H$ , the Heisenberg exchange dom inates and will lead to N eel ordering with opposite spins on the AB sublattices of the honeycomb lattice.

In the rst scenario, sketched schem atically in Fig. 1, the nite coupling K ondo transition is to a magnetically disordered ground state (spin liquid). In this scenario the AF ordered ground state does not survive up to the K I transition point for su ciently small J  $_{\rm H}$ . The K ondo physics has stabilized a spin liquid ground state in the region between the K I and AF ground states. The charge gap closes at  $\rm J_{1K}^{cr}$ , as the K I gives way to a sem i-m etal. The spin gap may or may not be nite, depending on the nature of the spin liquid. As  $\rm J_K$  is further reduced a transition to the N eel phase occurs. This scenario will of course be very exciting, if a spin liquid can indeed be stabilized as the ground state over some parameter range.

The other exciting possibility is that a continuous transition between two distinct orders (AF and KI) exists over a nite parameter range. This scenario is sketched schematically in Fig. 2. In this scenario SL is unstable to Neel ordering. This will be an example of the deconned quantum critical point mentioned earlier. Finally, scenarios in which an overlapping region, where a Neel state coexists with the Kondo insulator (similar to the square lattice result of Assaad<sup>10</sup>); or a rst order transition can not be ruled out. With these motivations we now sketch an outline of this paper.

In this paper we begin by a mean-eld study of the K ondo {Heisenberg model Eq. (1) on the honeycom b lattice. We adopt a ferm ionic representation for localized spins. We make a mean-eld decoupling of  $S_i$  § in the ferm ionic hopping channel. This is sometimes referred to as the resonating valence bond (RVB) decoupling. The K ondo interaction is decoupled in the usual mean-eld way with the hybridization \orderparameter"

FIG. 2: A nother scenario for the zero-tem preature phase diagram for the K ondo {H eisenberg H am iltonian at half-lling on the honeycom b lattice for som e (m aybe \ ne tuned") H eisenberg exchange  $J_H$  as a function of  $J_K$ . In contrast to the same m odel on a square lattice, both the quasi-particle gap denoted schem atically by the dotted-dashed line and N eel order param ater denoted by the solid line vanishes at  $J_K = J_K^{cr}$ .

 $\begin{array}{c} D_P \\ b = & a \ f_i^{ay} c_i^a \end{array}. \ \ The \ nonzero \ b \ will \ correspond \ to \ the \\ K \ I \ phase, where the gap in the dispersion is proportional to b. For any <math>J_H > 0$  we nd a continuous transition between the K I (b  $\neq$  0) and a spin liquid state (see F ig. 3). This spin liquid is characterized by D irac ferm ions coupled to U (1) gauge eld, and has been called the algebraic spin liquid (A SL), because the spin correlation decays as a power law and spin excitations are gapless.

As mentioned earlier, in the  $J_K$   $J_H$  limit, localized spins will be Neel ordered. Our mean eld decoupling can not capture this. Here we proceed with the assumption that the phase diagram is given by Fig. 1 and our main interest is to study the KI to SL transition. For this purpose the RVB decoupling is a reasonable starting point.

FIG. 3: The mean-eld phase diagram of the H am iltonian given by Eq.(1) in the  $J_K \mid J_H$  space (t = 1). For any  $J_H > 0$ , we nd a transition from the K I to the algebraic spin liquid.

The rest of the paper is devoted to studying the critical properties of the xed point that controls the transition from the KI to ASL. We note that neither phase breaks any physical symmetry, so that the transition is not described by the standard G inzburg-Landau-W ilson critical point. What changes at the transition is the dynamics of an emergent gauge eld. The emergent gauge eld is conned in the KI phase and it is deconned in the ASL phase.

In Sec. IIB we generalize our model by letting the spin indices to run from 1 to N rather than just  $\sup$  and down. The saddle point approximation (i.e. the mean-

eld) becomes exact as N  $\,!\,$  1 . In Sec. III we derive the low-energy Lagrangian density which sets the stage for a system atic 1=N expansion.

Section IV develops the propagator for the K ondo eld b, and the gauge eld a in the leading order. The K ondo eld propagator can be tuned to a massless point at  $J_K=J_K^{\rm cr}$ . In the  $J>J_K^{\rm cr}$  regime the b eld condenses to þj and we will be in the H iggs phase where the gauge eld is massive. This is nothing but the K ondo physics, where the excitation gap is proportional to þj. In the  $J<J_K^{\rm cr}$  regime the K ondo eld is not condensed, and is massive. The physics is described by D irac fermions coupled to a U (1) gauge eld. This eld theory, known as QED  $_3$ , has been studied extensively  $^{12\{16}$ , and is understood to be an algebraic spin liquid due to algebraic correlation of spins.  $^{12}$  This phase is believed to be decon ned.  $^{13}$ 

Section V A contains the main technical calculation of this paper. We calculate the exponent , which describes the diverging length scale of the transition. We consider a relativistic xed point, which allow sus to adopt standard eld theory methods. In Sec. VB we calculate the decay exponent of the staggered localized spin. In Sec. VI we show that the relativistic xed point is stable and is therefore the appropriate xed point to study for the transition.

### II. FINITE COUPLING KONDO TRANSITION

### A. Mean-Field Transition

Our starting point is the H am iltonian

where i and j live on the honeycomb lattice sites and a is the spin index: f"; #g. The  $s_i$  denotes the conduction electron spin at the site i and the capital  $S_i$  denotes the localized spin at the site i and they both are SU (2) spins with an SU (2) spin algebra. The conduction electron spin is given by

$$s_i = \frac{1}{2} c_i^{ay} \quad ab c_i^b; \tag{3}$$

where = ( $_x$ ;  $_y$ ;  $_z$ ) are the Paulim atrices. We adopt a ferm ionic representation for localized spins, where their Hilbert space  $f^*_i$ i;  $j^*_i$ ig, is constructed using Ferm ionic operators:

$$\dot{y}_{i}\dot{z} = f_{i}^{\sharp y} \dot{D}i;$$

$$\dot{y}_{i}i = f_{i}^{"y} \dot{D}i;$$
(4)

The anti{com m utation relation:

$$ff_i^{ay}; f_j^b g = ab ij$$
 (5)

together with

$$S_{i} = \frac{1}{2} f_{i}^{ay} _{ab} f_{i}^{b}$$
 (6)

will result in the SU (2) commutation relations for spin S. However, the Hilbert space of the localized spin  $S_i$  is restricted to only two elements:  $f \not \uparrow_i i ; j \not \vdash_i ig$ . Therefore identifying localized spin by ferm ionic operators given by Eq. (6) has to be accompanied by the constraint

X
$$f_{i}^{ay}f_{i}^{a} = 1:$$
 (7)

Combining Eqs. (3) | (7); together with the following identity for the Paulim atrices

$$ab cd = 2 ad bc ab cd$$
 (8)

one nds a ferm ionic representation of the spin {spin interactions in the H am iltonian of Eq. (2):

where the sum over the spin indices is understood.

The four-ferm ion interaction terms of Eqs. 9 and 10 will be replaced in the mean-eld (MF)  $\sin p \ln c$  ation by a quadratic interaction:

$$A = A_1 A_2 ! hA_1 i A_2 + A_1 hA_2 i hA_1 i hA_2 i;$$
 (11)

where  $\hat{A}$  denotes a generic four-ferm ion interaction term . To make the interaction quadratic one has to ignore (A  $_1$  hA  $_1$  i) (A  $_2$  hA  $_2$  i). So the mean-eld parameters have to satisfy the self-consistency condition:

$$\frac{\text{@F}_{\text{M} \text{ F}}}{\text{@} hA_{i}\dot{\textbf{I}}} = \overset{D}{A_{i}} \qquad hA_{i}\dot{\textbf{I}} = 0; \tag{12}$$

We make the interaction terms given by Eqs. (9) and (10) quadratic by choosing the following mean-eld parameters:

The rst param eter  $p_i \dot{p}^{i}$  lives on sites. The second param eter  $j_{ij} \dot{p}^{ia_{ij}}$  lives on links. We assume that these param eters have a constant magnitude throughout the lattice. When they take a non-zero value, small deviations from their \constant" magnitudes cost energy: they are locally stable.  $\dot{p}_i \dot{j} = b \in 0$  corresponds to the K ondo insulator phase, where the gap in the excitations is proportional to b. We also note that the conventional decoupling of  $S_i$  \$ leads to the anti-ferrom agnetic order

param eter hS $_{\rm iz}$ i. In this paper we adopt the alternative decoupling of Eq. (14), which is often called the RVB (Resonating Valence Bond) decoupling. RVB decoupling leads to a spin liquid state.

The U (1) gauge freedom in de ning f gives the freedom to elim in ate  $_{i}$  by the following gauge transform ation:

$$f_{i}^{a} ! e^{i \cdot i} f_{i}^{a};$$
  
 $a_{ij} ! a_{ij} + (i \cdot j);$ 
(15)

This transform ation leaves the total ux modulo 2

$$X$$
 $a_{ij} \pmod{2}$  (16)

through any closed loop invariant. Next we make a choice  $_{ij}$  = where is real. This choice corresponds to the case where the total ux through each hexagon modulo 2 is zero.

Our mean-eld choices result in the following mean-eld Hamiltonian:

$$\hat{H}_{MF} = t c_{i}^{ay}c_{j}^{a} + H x:$$

$$+ \frac{J_{K}b^{X}}{2} f_{i}^{ay}c_{j}^{a} + H x:$$

$$+ \frac{J_{H}}{2} X f_{i}^{ay}f_{j}^{a} + H x:$$

$$+ N J_{K}b^{2} + \frac{3J_{H}}{2} ;$$
(17)

where N is the number of unit cells. The di erent coe cients of the constant term s are due to the fact that there are 2 sites as opposed to 3 links per unit cell. We also mention that, at the mean-eld level, the constraint given by Eq. (7) is enforced on average by having a chemical potential for fiferm ions. This chemical potential is zero due to fiferm ions particle hole symmetry.

From  $\hat{H_{\text{M F}}}$ , the M F free energy can be calculated numerically. M F parameters satisfying the self-consistency condition are then obtained. The numerics con rm the nite coupling K ondo transition in a background , for any  $J_{\text{H}} > 0$ . Next we show this nite coupling K ondo transition analytically and nd the exponent

$$j_{0}j/(J_{K} J_{K}^{cr});$$
 (18)

by focusing on the low-energy theory near the Dirac nodes.

When focus are too the celectrons kinetic term to  $c_i^{ay}c_i^a+$  H x: . When do the Fourier transformation

$$c_{A}(k) = \frac{1}{N} e^{ik} c_{A}(R)$$
 (19)

where R are the Bravais lattice vectors and  $c_A$  (R) is the conduction electron annihilation operator at the A sublattice site of the unit cell positioned at R. The similar transformation is done to get  $c_B$  (k). Conduction

FIG. 4: The B rillou in zone of the honeycom b lattice. Comers of the B rillou in zone are where the tight-binding gap vanishes. The independent low-energy modes are denoted by the lled-circles around the two D irac nodes  $\ k_{\rm D}$ .

electrons kinetic term in m om entum space w ill take the form :

where

$$(k) = 1 + e^{ik} (2 ) + e^{ik} (21 + 2);$$
 (21)

and  $_1 = 1(1;0)$  and  $_2 = 1(_1=2;_3=2)$  are two of the three vectors that connect A sublattice sites to nearest neighbor B sublattice sites. I is the length between nearest neighbor sites which will be set to the unit length: l=1.

(k) vanishes at the D irac nodes  $\quad k_D$  , which is given by

$$k_D = 0; \frac{4}{3}; \frac{4}{3};$$
 (22)

Near the nodes as schematically represented by the lled circles in the Fig. 4, (  $k_D + q$ ) is given by

$$(k_D + q) = \frac{3}{2}(iq_1 - q_1) + 0 (q^2)$$
: (23)

To write the conduction electron kinetic term near the D irac nodes, we use the following notation, which will also be helpful in Sec. III:

(q) 
$$c_A (k_D + q)$$
  
 $c_B (k_D + q)$ : (24)

A fter collecting Eqs. (20) (24), we get

where \ " is used, since in contrast to Eq. (20) the momentum sum is restricted to be near the D irac nodes.

Next we obtain the energy dispersion near the node  $+\,k_D$  . The MF Ham iltonian in momentum space and near the node +  $k_D$  , denoted by  $\hat{H}_+$  (q), is given by

$$\hat{H}_{+}(q) = {}_{+}(q)^{y} + {}_{+}(q)^{y} + {}_{+}(q) ;$$
 (26)

where we have dropped the constant term of Eq. (17) and we have used a similar notation as in Eq (24) for the f ferm ions:

(q) 
$$f_A (k_D + q)$$
  
 $f_B (k_D + q)$ : (27)

The 4  $4 \text{ m atrix H}_+$  is given in block form by

$$H_{+} = \frac{1}{2} \begin{array}{ccc} 2v_{c} (q_{1\ 2} + q_{2\ 1}) & J_{K} b \\ J_{K} b & 2v_{f} (q_{1\ 2} + q_{2\ 1}) \end{array} ; \quad (28)$$

where  $v_c$  and  $v_f$  are given by:

$$v_c = \frac{3}{2}t;$$
 (29)

$$v_f = \frac{3}{4} J_H :$$
 (30)

It will be clear why notations  $v_c$  and  $v_f$  is used shortly. It is straightforward to diagonalize the above matrix. The four eigenvalues are given by:

$$e(q) = (v_c v_f)\dot{g}\dot{j} (v_f + v_c)^2q^2 + J_K^2b^2 = 2:$$
(31)

We have dropped the subscript + from e(q), since the dispersion near the other node is the same.

To understand the above dispersion better, we mention its behavior in di erent regim es:

> b = 0. The MF Hamiltonian has two decoupled parts: kinetic terms for the conduction electrons and for f ferm ions. In this case the 4 eigenvalues near the nodes become vejqj and vejqj. They are the massless Dirac dispersions for conduction electrons c and ferm ions f with velocities vc and vf respectively. The phase with b = 0 is an algebraic spin liquid phase as will be clear in Sec. V B. This is closely related to the work of Rantner and Wen, where Dirac fermions coupled to a gauge eld was found to be an algebraic spin liquid. 12

 $y = v_c$ ; b  $\neq 0$ . The dispersion is the massive relativistic D irac dispersion

$$e(q) = v_c^2 q^2 + (J_K b=2)^2;$$
 (32)

where each eigenvalue is doubly degenerate.  $J_K$  b=2 is the mass of our relativistic quasi-particles. In Sec. III, we will see that the low-energy theory, in the  $\lim_{t\to\infty} it v_f = v_c$ , is Lorentz invaraint. The above relativistic dispersion is a sign of this Lorentz invariance.

sign of  $\gamma$  . The sign of  $(v_f)$  has dram atic consequences on the shape of the dispersion and also on the continuum formulation of the model near the phase transition. Due to the coupling between f-ferm ions and the conduction electrons the free energy is not invariant under the mapping 7 In the K ondo insulating phase (b & 0); the dispersion for  $v_f > 0$  is gapped. However the dispersion for  $v_f$  < 0 has a gapless ring around each D irac node with the radius

$$q_c = \frac{J_K b}{2^P W_{V_f}}$$
 (33)

It turns out that the positive (self consistent)  $(v_{\rm f} > 0)$  is more stable. This is not surprising from the above fact that the dispersion for  $v_f > 0$  is gapped as opposed to  $v_{\rm f}$  < 0 which is gapless. W e are only concerned with the stable solution in this paper.

The MF transition at zero temperature can be analyzed by m in im izing the total energy

$$E = 4 \sum_{e(q) < 0}^{X} e(q) + N J_K b^2 + \frac{3J_H}{2}^2$$
; (34)

$$\frac{\partial E}{\partial b} = 0$$
; and  $\frac{\partial E}{\partial a} = 0$ : (35)

The coe ecient 4 = 2 2 is for counting spins and the two nodes. The condition  $\frac{\partial E}{\partial t} = 0$  at b = 0 results in the self consistent , which varies slow ly across the transition. For  $v_f > 0$ , the negative energy bands are given by  $(v_f - v_f)\dot{q}\dot{q} = \frac{v_f}{(v_f + v_c)^2q^2 + J_K^2b^2} = 2. \ Therefore$ 

$$(v_{\rm f} + v_{\rm c})^2 q^2 + J_{\rm K}^2 b^2 = 2.$$
 Therefore

$$X \qquad e(q) = X \qquad Q \qquad \overline{(v_f + v_c)^2 q^2 + J_K^2 b^2}; \qquad (36)$$

Combine Eqs. 34 36, to arrive at the self-consistency equation for b:

$$\frac{2}{N} \frac{X}{v_{g}} = \frac{J_{K}}{(v_{f} + v_{c})^{2} q^{2} + J_{K}^{2} b^{2}} = 1:$$
 (37)

It is clear from the above equation that the K ondo phase does not survive down to  $J_K = 0$ , in contrast to the case when the conduction band possess a Ferm i surface. The Kondo insulator phase disappears at a nite coupling constant  $J_K^{\text{cr}}.$  Taking the  $lim\ it\ N\ !\ 1$  , we  $\ nd\ the$ following dependence of the Kondo parameter jojas a function of the distance from the transition  $J_K$ 

$$\begin{array}{ll} \text{bj/} & (J_{K} & J_{K}^{\text{cr}});\\ \\ J_{K}^{\text{cr}} = & \frac{v_{c} + v_{f}}{i}; \end{array} \tag{38}$$

1 is a large-m om entum cuto around the w here Dirac nodes  $k_{\!\scriptscriptstyle D}$  .

To sum marize, the MF solution has two interesting features:

The K ondo insulator phase disappears at a nite coupling constant.

The K ondo condensate <code>bj</code> vanishes linearly as the distance from the critical point. We emphasize that a Landau {type expansion for the bmean-eld parameter would yield the result <code>bj/</code>  $(J_K J_K^{cr})^{1=2}$  near the transition point. The appearance of nontrivial critical exponent at the mean-eld level is characteristic of the coupling of b to gapless ferm ions which is addressed systematically in the 1=N expansion.

### B. Large N Form ulation: M ean-Field Justi ed

In this section we extend the physical model with two spin-avors to a generalized model with N spin-avors.  $^{11}$  W e show that the mean-eld solution is the stable solution in the in nite N lim it.

The conduction electrons kinetic term  $c_i^{ay}c_j^a+H$  x: is already in the generalized form. We just let the spin index a to run from 1 to N. The spin {spin interactions as written in Eqs. 9 and 10 is also easily generalized by letting the spin indices to run from 1 to N. In addition we control these interactions by replacing  $\frac{1}{2}$  with  $\frac{1}{N}$ . So the generalized version of the H am iltonian of Eq. (2) is given by

where the sum over spin indices is understood. The above Hamiltonian has to accompanied by the local constraint:

X 
$$f_{i}^{ay}f_{i}^{a} = \frac{N}{2}$$
: (40)

The above generalized model will coincide with the Hamiltonian Eq. (2) for N=2. In fermion coherent state representation, using G rassmann variables, the Euclidean Lagrangian and the partition function take the form

$$L_{E} ([c;f;a_{0}]) = \begin{cases} X \\ c_{i}^{a}(x_{0})@_{0}c_{i}^{a}(x_{0}) + f_{i}^{a}(x_{0})@_{0}f_{i}^{a}(x_{0}) \end{cases}$$

$$i \qquad \qquad !$$

$$ia_{i0} f_{i}^{a}(x_{0})f_{i}^{a}(x_{0}) \frac{N}{2} + H;$$

$$Z$$

$$Z = D [ccffa_{0}]e^{\int dx_{0}L_{E}(x_{0})};$$
(41)

where  $x_0$  denotes the imaginary time. The elda $_{i0}$ , when integrated over, will produce delta functions at each site enforcing the local constraint given by Eq. 40. The notation  $a_{i0}$  is used because it will serve as the time component of the emergent gauge eld.

Next we do the standard H ubbard {Stratonovich transform ation to decouple the four-ferm ion terms in the action at a cost of introducing the complex elds  $b_i$ , which live on sites and ij, which live on links:

$$L_{E} ([c;f;b;;a_{0}]) \times X = c_{i}^{a}(\theta_{0}c_{i}^{a} + c_{i}c_{j}^{a} + c_{i}c_{i}^{a}) \times X + f_{i}^{a}(\theta_{0} + ia_{0})f_{i}^{a} + iN a_{i0} = 2$$

$$\times \frac{X}{I} \times \frac{N}{J_{H}} j_{ij}j_{f}^{2} + ij_{i}f_{i}^{a}f_{j}^{a} + ij_{i}f_{j}^{a}f_{i}^{a}$$

$$\times \frac{N}{J_{K}} j_{hiji} + b_{i}c_{i}^{a}f_{i}^{a} + b_{j}f_{i}^{a}c_{i}^{a};$$

$$\times \frac{N}{J_{K}} j_{hij}j_{f}^{2} + b_{i}c_{i}^{a}f_{i}^{a} + b_{j}f_{i}^{a}c_{i}^{a};$$

$$\times \frac{Z}{I} = D [ccffbb] = a_{0} e^{\int dx_{0}L_{E}(x_{0})};$$

The  $x_0$  dependence of G rassmann and complex elds in the Lagrangian is understood as well as the dropped indices in the measure of the path integral.

The action is quadratic in the Ferm ionic elds and it can be integrated out at the cost of obtaining an elective action for  $b_i$  and  $i_j$  elds, which is highly nonlocal. Since there is no mixing of dierent spin-avors, the resulting elective action will be proportional to N:

$$\frac{L_{E} ([b; ])}{N} = \log \det M + \frac{1}{J_{K}} X_{i} j_{b_{i}} j_{i} + \frac{1}{J_{H}} X_{hiji} j_{ij} j_{i};$$
(43)

M is a 4N 4N Herm itian matrix, which encodes the quadratic interaction of the ferm ionic elds as given by Eq. (42), e.g. M  $_{\rm c_if_i}$  =  $\rm b_i.^{22}$  The \detM " makes the elds and ii elds nonlocal.

The saddle point approximation for the above Lagrangian  $L_E$  ([b; ]) is exact as N ! 1 . The saddle point equations will be the mean-eld equations given by Eq. (12), and this is how the mean-eld developed in the previous section is justified. Furtherm ore the Lagrangian given in Eq. (42) will set the stage for a systematic 1=N expansion around the mean-eld solution.

## III. BEYOND MEAN FIELD:LOW ENERGY EFFECTIVE FIELD THEORY

In this section we obtain the Lagrangian density near the critical point starting from the microscopic Lagrangian. There are two independent nodes  $\,k_{\!D}\,$  and

near each node there are ferm ions from A and B sublattices. We package these c and f ferm ions into four component spinors and . This is done in a way to make the kinetic terms for both elds look the same.

Since there is no m ixing of di erent spin- avors in the m icroscopic Lagrangian Eq. (42), we will drop this index throughout the derivation of the Lagrangian density. The spin- avor index will be resurrected at the end.

The kinetic term for the conduction electrons was discussed in Sec. IIA:

Note that under the transform ation (q)!  $_2$  (q) the second term has the same form as the rst one. We combine the two 2-component spinors, associated with the two Dirac nodes, to form a 4-component spinor (q):

(q) 
$${}^{+}_{2} {}^{(q)}_{(q)} :$$
 (45)

To write the kinetic term in terms of (q), we de ne the 4 block diagonal matrices i:

$$_{i}$$
  $_{0}^{i}$   $_{i}^{0}$   $_{i}^{0}$  =  $_{i}$   $_{12}$   $_{2}$ : (46)

The kinetic term then takes the form

A first taking the continuum limit, the Lagrangian density corresponding to this H am iltonian is:

$$L_{E}^{(1)} = {}^{y} Q_{0} \quad \text{iv}_{C} \, {}^{y} (_{2}Q_{1} + _{1}Q_{2}) :$$
 (48)

To use the  $\,$  eld theory techniques one would write L  $_{\rm E}^{(1)}$  in a di erent form

$$L_{E}^{(1)} = {}_{3}Q_{0} + V_{C} ( {}_{1}Q_{1} + {}_{2}Q_{2}) ;$$
 (49)

where is de ned to be

(51)

Next we focus on  $^{P}_{ij}f_{i}^{a}f_{j}^{a}+_{ij}f_{j}^{a}f_{i}^{a}$  term in Eq. (42). Consider the mean-eld case  $_{ij}=>0$ . The phase uctuations will be included as gauge eld uctuations later on. Ignoring the phase uctuations, this term looks exactly like the kinetic term of the conduction electrons given by Eq. (44), but with an opposite sign:

$$f_{i}^{y}f_{j} + H \text{ c: } v_{f} + (q)^{y}(q_{2} q_{1}) + (q)$$

$$X$$

$$+ v_{f} + (q)^{y}(q_{2} + q_{2}) + (q)$$

We make this look like Eq. (47) by a further transformation to absorb the minus sign and we again combine the 2-component spinors near the two nodes to form a 4-component spinor (q):

(q) 
$$\lim_{\dot{1}_{1}}^{3+} (q) :$$
 (52)

On the grounds of gauge invariance, we write the Lagrangian density corresponding to the  $\$  term of the f ferm ions

$$L_E^{(2)} = {}_{3}(@_{0} \text{ ia}_{0}) + v_f \qquad {}_{1}(@_{1} \text{ ia}_{1}) + {}_{2}(@_{2} \text{ ia}_{2}) ;$$
(53)

where the non-compact gauge eld a (x) appears as a connection to produce covaraint derivative. It is related to the the phase  $a_{ij}$  through the relation a  $(x) = a_{ij}^{i}_{ij}$ , where  $^{i}_{ij}$  is the unit vector connecting the site i to the site j. We have used the same de nition as in Eq. (50):

En route to the continuum limit, we have implicitly dropped the compact character of the gauge ed. This is only valid if the gauge uctuations are not very strong. In the imaginary time evolution, there will be events on the lattice scale that change the ux of the gauge edd by 2. If these events do not proliferate, we will be in small gauge coupling constant regime and taking the continuum limit is justied. We return to this point at the end of this section.

Now we focus on the interaction term  ${}^{p}_{i}b_{i}c_{i}^{y}f_{i}$ . We write this in the momentum space and restrict c and f ferm ions momentum to be near  $k_{D}$ , and b momentum to be near k=0. Simple manipulations

$$_{+}^{y}(q)_{+}(q^{0}) = _{+}^{y}(q)_{3}(_{3}+(q^{0}));$$
 (55)

$$^{y}$$
 (q)  $(q^{0}) = (_{2} (q))^{y} _{3} (i_{1} (q^{0}));$  (56)

combined with the de nitions for and elds, result in

$$^{y}_{+}(q)_{+}(q^{0}) + ^{y}(q)_{-}(q^{0}) = ^{y}_{-}(q)_{3}(q^{0})_{3}$$

$$= (q)_{-}(q^{0})_{3} (q^{0})_{3} (q^{$$

Therefore in the continuum  $\lim_{P}$  in it the Lagrangian density corresponding to  $\lim_{i}$   $b_i c_i^y f_i + b_i f_i^y c_i$  will be

$$L_E^{(3)} = b + b$$
 : (58)

Now collect  $L_{E}^{\,(1)}$  ,  $L_{E}^{\,(2)}$  and  $L_{E}^{\,(3)}$  , to write the Lagrangian density

$$L_{E}^{v_{c}=v_{f}} = a v_{c}=v_{f} @ a + a @ ia) a$$
  
+  $b^{a} a + b^{a} a + \frac{N}{J_{V}} p^{2} + ;$  (59)

where the spin indices are restored. \* is de ned to be

$$% (3; %1;%2); (60)$$

and is a shorthand for  $^{\$}$  with \$=1.T he velocity  $v_f$  in Eq. (53) is absorbed by scaling x and a. As a result, the velocities enter only as the dimensionless ratio  $v_c = v_f$  via  $^{v_c = v_f}$ .

Taking the continuum limit, which is essentially a coarse graining process, generates new interactions among coarse grained elds. The ellipsis in Eq. (59) denotes such new interactions. Not all possible terms are allowed though. Since the coarse graining process does not break symmetries of them icroscopic Lagrangian, the generated interactions should respect these symmetries. To

Next we set  $v_{\rm f}=v_{\rm c}$  to make the low-energy theory Lorentz sym metric. The action in the presence of two di erent velocities will not respect the Lorentz sym metry. Under RG transform ation | in the absence of Lorentz sym metry | the velocities will change, since there is no sym metry to protect them from changing. We shall show later that the Lorentz invaraince is protected in the RG sense, in that small deviation from  $v_{\rm f}=v_{\rm c}$  will scale to zero under RG transformation. Thus we focus our discussion on this Lorentz invariant xed point.

The Lorentz-sym metric Lagrangian density is given by:

$$L_{E} = {}^{a} @ {}^{a} + {}^{a} @ ia) {}^{a}$$

$$+ b {}^{a} {}^{a} + b {}^{a} {}^{a} + \frac{N}{J_{K}} p^{2}$$

$$+ \frac{N}{2e^{2}} ( @ a)^{2} + N gj(@ + ia)b^{2} + ;$$
(61)

where  $L_E$  is a shorthand for  $L_E^\$$  with \$=1. The last two term s are two examples of the term s that will be generated in the coarse graining process. They are written on the grounds of gauge invariance. In Sec. VI we show that these new terms and other terms grouped in the ellipsis are irrelevant at our nite coupling K ondo transition xed point. Embedded in Eq. (61), is the QED 3 Lagrangian desnity

<sup>a</sup> (@ ia) <sup>a</sup> + 
$$\frac{N}{2e^2}$$
 ( @ a)<sup>2</sup> + :

 $\rm Q\,E\,D_3$  has been studied before as the low-energy theory of the staggered ux phase  $^{12}\{^{14}$  . We have used the recent result  $^{13}$  about the irrelavance of instanton events near the  $\rm Q\,E\,D_3$  xed point and took the gauge eld to be noncompact. In our formulation the physical SU (2) theory corresponds to N=2 four-component spinors. It could have been formulated as N  $_{\rm f}=4$  two-component spinors near each node in the Brillouin zone. To go back and forth between these formulations one just needs to use N  $_{\rm f}=2\rm N$  .

## IV. 1=N SYSTEM ATIC EXPANSION: FIELD PROPAGATORS

The Lagrangian density Eq. (61), derived in the previous section, allows us to develop the machinery of 1=N expansion. The propagators for the elds b and a are of

order 1=N in the large N lim it. This will allow us to calculate di erent propagators and scaling dim ensions order by order in 1=N .

We start with our notations for propagators of the ferm ion elds, and .We use a single line notation for the eld propagator and a double line for propagator:

$$\stackrel{a \quad b}{i \quad j} \quad (q) = i \xrightarrow{q} j = \stackrel{ab}{iq} \stackrel{i}{ij}; \quad (63)$$

$$\stackrel{a \quad b}{i \quad j} \quad (q) = i \xrightarrow{q} j = \stackrel{ab}{iq} iq \stackrel{1}{ij}; \quad (64)$$

where Feynman's slash notation

$$g = q \tag{65}$$

is used.

The Gauge Field a .Our Lagrangian density  $L_{\text{E}}\,$  has a QED  $_{3}$  piece

<sup>a</sup> (@ ia) <sup>a</sup> + 
$$\frac{N}{2e^2}$$
 ( @ a)<sup>2</sup> + ; (66)

which has been studied before.  $^{12}$  16 We refer the reader to the Appendix B of Ref. 14 for the calculation of the QED<sub>3</sub> gauge propagator. The QED<sub>3</sub> gauge propagator, in the leading order, is given by:

ha a i (q) = 
$$\frac{q}{N \text{ jqj}} + \frac{q q}{q^2} (1)$$
; (67)

where is the Fadeev-Popov gauge xing parameter.
= 1 corresponds to the Feynman gauge and = 0
to the Landau gauge. The jrj dependence comes from
(62) calculating the self-energy

$$\begin{array}{c}
k + q \\
\vdots \\
k
\end{array}$$
: (68)

The charge e has disappeared form the nal result. This charge appears if one includes the  $q^2$  dependence in the denom inator of the gauge propagator. But in the small q (long distance)  $\lim$  it, the jqj dependence dom inates over  $q^2$  term, no matter how large e is. A nother way to say this is that the QED  $_3$  is self(critical. It will ow to a stable xed point | even if we start with a large gauge charge e | at least for som e large N .

The gauge propagator of our theory, in the leading order, will come solely from the f-ferm ion bubble, given diagram matically in Eq. (68). The b propagation does not contribute to the gauge eld's self energy in the

leading order. Therefore, in the leading order, ha a i (q) of our Lagrangian density Eq. (61) is the same as  $Q ED_3$ .

The Kondo Field b. The b eld propagator, in the leading order, is given by:

hdb i 
$$^{1}$$
 (q)  $G_{b}^{1}$  (q) =  $G_{b0}^{1}$  (q)  $(q)$  ; (69)

where  $G_{b0}^{1}(q) = N = J_K + O(q^2)$ . The self energy is easily obtained to be:

$$k + q$$

$$= (ij)N \frac{Z}{(2)^d} Tr k^1 k + q^1$$

$$k = \frac{N}{4} jqj + \frac{2N}{2}$$
(70)

This will result in the following b propagator:

hdo i (q) = = = = 
$$\frac{q}{N \ (\dot{q}\dot{j} + m_b)}$$
; (71)

where m  $_{\text{b}}$  is the e ective m ass of the b propagator, and is given by:

$$m_b = \frac{4}{J_K} \frac{8}{2} / (J_K^{cr} J_K);$$
 (72)

where  $J_K^{\rm cr}$  is given by  $J_K^{\rm cr}={}^2=(2)$ .  $J_K^{\rm cr}$  is of course nonuniversal, i.e. it depends on how we regularize the integral in Eq. (70). However the nalresult that

$$m_b / (J_K^{cr} - J_K)$$
 (73)

is scheme independent.

The above result, that the mass of the beld can be tuned to zero, serves as a sanity check for the mean-eld result of the nite coupling K ondo transition obtained in Sect. ITA.

Since the selfenergy has jrj dependence, in the long distance (small jrj)  $\lim$  it, it dominates over the  $q^2$  dependence coming from j0  $\inf$ . The  $q^2$  dependence is ignored in the nalexpression given in Eq. (71). In the RG language, the j0  $\inf$  term is irrelevant at the xed point.

We also mention a further notation for the massless b propagator. We have used the \double-dashed" line notation for b propagator away from the critical point. We use a \sim ple-dashed" line for the b propagator at the critical point:

$$-- \stackrel{q}{\blacktriangleleft} --- = \frac{4}{N \ \dot{q} \dot{j}} : \tag{74}$$

Except for the calculation of  $_{\rm b}$ , done in Sec.V A 1,m assless b propagator of Eq. (74) is used throughout the paper.

The b propagator given by Eqs. (71) and (74) is gauge invariant. This will not be the case to all orders in perturbation theory. The reason is as follows. There is a gauge freedom in dening. Given that the action is gauge invariant, the interaction b  $^a$   $^a$  + b  $^a$   $^a$  dictates that gauge transform ation

$$(x) ! e^{i (x)} (x)$$
 (75)

has to be accompanied by

$$b(x) ! e^{i(x)}b(x);$$
 (76)

since can not tolerate any gauge freedom. So the b propagator in principle should have a gauge dependence. However to leading order, the gauge eld propagator does not enter in b's self energy and that is why the leading order b propagator given by Eq. (71) is gauge invariant.

## V. CRITICAL PROPERTIES OF THE FIXED POINT

# A. D ivergence of T he C orrelation Length: the $\mbox{\bf Exponent}$

In this section we go through the calculation of the divergence of the correlation length near the xed point by calculating the exponent:

$$/\frac{1}{jJ_{K}} J_{K}^{c} j: \qquad (77)$$

We mention rst what the correlation length means by looking at the K ondo {H eisenberg H am iltonian in di erent regim es. At  $J_K = 0$  the Kondo{Heisenberg Ham iltonian has two decoupled parts: the kinetic term for the conduction electrons and the anti-ferrom agnetic Heisenberg exchange of the localized spins. There is no entanglem ent between conduction electrons and the localized spins in the ground state. In the large  $J_{\mbox{\scriptsize K}}$  lim it the K ondo term dom inates over the H eisenberg exchange. The ground state is the product of conduction electrons and the localized spin singlets at each site. Since we are at half lling every conduction electron is taken away by a localized spin. There is entanglement in the ground state. But the entanglement is restricted to one site. As we approach the critical point, the \size" of these K ondo singlets grows and it eventually diverges at the critical point. The scale associated with these K ondo singlets is what we mean by the correlation length .

The relevant ow of the mass term  $\mbox{bf}$  will introduce a diverging length scale  $\mbox{b}$  near the transition point. Since the K ondo phase is charactarized by the condensation of the b eld, the correlation length is proportional to  $\mbox{b}$ . This results in

$$= b:$$
 (78)

We obtain by using the scaling relation<sup>20</sup>

$$b = \frac{b}{2}; \tag{79}$$

where  $_{b}$  and 2  $_{b}$  characterize the power-law behavior of two-point function  $G_{b}(k;m_{b})$ 

$$hb(x)b (x^{0})i = \frac{Z}{(2)^{3}}e^{ik} (x^{0})^{3}G_{b}(k;m_{b})$$
 (80)

in two di erent lim its:

$$G_b(0; m_b! 0) / m_b^b;$$
 (81)

$$G_b(k! 0;0) / kj^{2+b}$$
: (82)

It should be noted that since b is not gauge invariant,  $_{\rm b}$  and  $_{\rm b}$  are not gauge invariant. However by denition, given by Eq. (77), is a gauge invariant quantity. Since it is not a priori obvious that the scaling relation given by Eq. (79) is gauge invariant, we calculate  $_{\rm b}$  and  $_{\rm b}$  in a general gauge, and show that derived from Eq. (79) is indeed gauge invaraint.

The methods we use to calculate  $_b$  and  $_b$  are very di erent. The calculation of  $_b$  is done by directly calculating the G reen's function  $G_b\left(0;m_b\right)$ . Calculating  $_b$ , in this manner, is much more involved. Instead, we calculate  $_b$  by relating  $_b$  to the scaling dimension of  $^a$   $^a$ . The scaling dimension of  $^a$   $^a$  is then obtained by perturbing the Lagrangian density  $L_E$ !  $L_E$  +  $^a$   $^a$  and applying the Callan–Symanzik equation for the propagator  $^a$   $^a$ , in the presence of the perturbation, to obtain the ow of the composite operator  $^a$   $^a$ , and thus extracting its scaling dimension.

1. b

To calculate  $_b$  we calculate  $G_b$   $(0; m_b)$ , i.e. the uniform part of the b propagator slightly away from the critical point. From the calculations in the previous section leading to Eq. (71) we have

$$G_{b}^{1}(0;m_{b}) = N \frac{m_{b}}{4} \qquad {}^{1=N}_{b}(0;m_{b});$$
 (83)

where  $_{b}^{1=N}$  (0; m  $_{b}$ ) is given diagram atically by

This results in

$$G_b^{-1}(0; m_b) = N \frac{m_b}{4} - 1 \frac{4(-1)}{N^{-2}} log(m_b = )$$

$$/ m_b^{-1} \frac{4(-1)}{2N};$$
(85)

from which we obtain

$$_{b} = 1 \frac{4 (1)}{^{2}N}$$
: (86)

The integrals are evaluated in the dimensional regularization scheme  $e^{.23,25}$  The mass scale in this scheme is introduced to keep track of dimensions in d dimensional integration and plays the role of a UV cuto . A simple pole in the dimension d rejects the logarithmic divergence of the original 3 dimensional integration. We only keep track of the IR divergent parts. As far as the universal properties of the xed point are concerned this regularization would give the same answer as a cuto regularization.

We brie y discuss the diagrams involved in  $_{\rm b}^{\rm 1=N}$  (0;m $_{\rm b}).$  The rst diagram of Eq. (84) has no m $_{\rm b}$  dependence. The second and third diagrams are equal and are given by:

The last diagram of Eq. (84) contains the vertex that

couples b bosons with the gauge eld:

In the calculation of  $_{\rm b}^{\rm 1=N}$  (0;m ) the momentum entering this vertex is zero. The result of this integral for k=0 is

$$\frac{d^{3}p}{(2)^{3}} \operatorname{Tr} p^{1}p^{1} \quad p \quad q^{1} = \frac{q}{4jqj}; \quad (89)$$

Having the result of the above integral, we get

2. h

 $_{\rm b}$  is easily related to the scaling dimension of the beld at the critical point [See Eq. (82)]:

$$_{b} = 1 + 2[b];$$
 (91)

Since the only way for the b eld to propagate is to decay into a, the scaling of the self energy of b is the same as the propagator of the composite operator a. This observation results in

$$[b] = 3 [a a]; (92)$$

Thus  $_{\rm b}$  is known once we know the scaling dim ension of the composite operator  $^{\rm a}$   $^{\rm a}$ .

The scaling dimension of  $^{a}$  is obtained by adding the perturbation

$$L_E ! L_E + a a$$
 (93)

to the Lagrangian density and obtaining the  $\,$  ow of  $\,$  by studying the Callan-Sym anzik equation for the propagator  $\,$  a (x)  $\,$  a  $(x^0)$  .

The Callan-Sym anzik equation is essentially the \scale invariance" relation.  $^{23,24}$  Near the xed point, a change in scale has to be accompanied by the ow of some coupling constants and scaling of the elds to maintain scale

invariance. For the propagator under consideration it will read

$$\frac{\theta}{\theta}$$
,  $+\frac{dC_m}{d}$ ,  $\frac{\theta}{\theta C_m}$  a (e'x) a (e'x<sup>0</sup>) = 0; (94)

where and are scaling dimensions of the elds and . The set C includes the coupling constants that ow. For the perturbation given by Eq. (93) it has only  $1 \text{ element}^{28}$ 

$$C = f g: (95)$$

It is more convenient to apply the Callan-Symanzik equation to the momentum-space Green's function  $^{a}$   $^{a}$   $^{a}$   $^{(k)}$ 

a a 
$$(k) = \frac{Z}{(2)^3} e^{ik(x - x^0)}$$
 a  $(x)$  a  $(x^0)$  : (96)

Eq. (94) results in

$$\frac{\theta}{\theta'}$$
 + (3 ) +  $\frac{d}{d}$   $\frac{\theta}{\theta}$  a a (e 'k) = 0; (97)

where  $\3$ " is coming from the scaling of the measure  $\$ d $^3$ k in the integrand of Eq. (96).

To apply the Callan-Sym anzik equation we set need to obtain and . The gauge dependant is obtained by calculating the propagator

The result is

a a 
$$(k) = (ik)^{-1} + \frac{1}{N} + \frac{2}{2} + \frac{4}{2} + \frac{4}{2} + \frac{1}{2} + \frac{$$

from which we get

$$= 1 + \frac{1}{N} \frac{1}{2} + \frac{2}{2} ( 1) :$$
 (100)

Sim ilarly, calculating the gauge invariant conduction

electron propagator

by

results in the gauge invariant

$$= 1 + \frac{1}{3^{2}N}:$$
 (102)

The logarithm ic infrared divergence of Eq. (101) can be interpreted as the scaling of the quasi-particle weight Z, de ned by  $^{a}$   $^{a}$  (k) = Z (i $\bigstar$ )  $^{1}$ . The scaling form of Z which is consistent with Eq. (101) is

$$Z = j^{\frac{k}{3}} j^{\frac{2}{3^{1}}}$$
: (103)

The vanishing of the Z factor as  $k \,! \, 0$  can in principle be seen in tunnelling experiments. This non-Ferm i liquid behavior arises, because at the K I{ASL} xed point, there are very strong scattering of conduction electrons into the f-ferm ions. This is due to the fact that the beld which causes the scattering has become massless.

The next step is to obtain  $^{a}$   $^{a}$  (k) in the presense of the perturbation  $^{a}$   $^{a}$  given by Eq. (93). This perturbation is represented diagram m atically by

The diagram matic expression for a a is then given

It results in

a a (k) = 
$$(k)^2 1 \frac{4}{3^2 N} \log(k)$$
; (106)

Callan-Sym anzik equation  $\mathbb{E} q. (97)$ ] applied to the above propgator results in

$$\frac{d}{dl} = 1 + \frac{8}{3^{2}N} + \frac{2}{2N} \quad (107)$$

The above relation together with Eq. (92) yields:

$$[b] = 1 + \frac{1}{N} + \frac{8}{3^2} + \frac{2}{2}$$
 (108)

Combine this with Eq. (91) to get

$$_{b} = 1 + \frac{1}{N} \frac{16}{3^{2}} + \frac{4}{2} ( 1) :$$
 (109)

Collecting what we have obtained for  $_{\rm b}$  and  $_{\rm b}$  given by Eqs. (86) and (109), together with the scaling relation given by Eq. (79), we arrive at the gauge invariant

$$= 1 + \frac{16}{3^{2}N} : \tag{110}$$

Note that the 1=N uctuations have brought us further away from the generic 1=2+0 () result one would obtain for a stable xed point in an expansion (which is an expansion around the gaussian action), assuming there exists such a stable xed point.

### B. Staggered Spin Correlation

We continue the study of the physical properties of our KI{ASL} xed point by obtaining staggered spin M =  $S_A$   $S_B$  correlation at the xed point. The correlation is algebraic and our xed point is an algebraic spin liquid xed point.

Since the decay exponent of hM (x) M (x) i and hM  $^+$  (x)M  $(x^0)$ i is the same, it su ces to nd the scaling dimension of M  $^+$ . In terms of the eld operators M  $^+$  (x) is

$$M^{+}(x) = {}^{1}(x)M^{-2}(x);$$
 (111)

where M is 4 4 m atrix, which should be obtained from the relation between the eld and the microscopic operators developed in Sec. III. Physically 1 and 2 represents " and #. In 1=N expansion they are 2 indices among many. M is obtained to be<sup>29</sup>

$$M = 1$$
 3: (112)

We should add this perturbation to the Lagrangian and study its ow. However  $^1\,(x)M$   $^2\,(x)$  m ixes with  $^1\,(x)M$   $^2\,(x)$ . In other words M  $^+$  is not a scaling operator. Having this in m ind, we perturb the Lagrangian density by

$$L_E = U_+$$
  $^1(x)M$   $^2(x) + u_+$   $^1(x)M$   $^2(x)$  (113)

and study the Callan-Sym anzik equation for the propagators  $^{1}$   $^{2}$  (k) and  $^{1}$   $^{2}$  (k). The result (obtained in Appendix B) is

We emphasize that o {diagonal term s make 1=N correction to the scaling dimension of the staggered spin. This is because the scaling dimensions of and are equal in the in nite N limit. This is similar to the importance of o -diagonal term s in the 1st order degenerate perturbation theory in quantum mechanics. Parameter of the largest eigenvalue 1 + 2 7 +  $\frac{1}{73}$  = (3 2N) of

The largest eigenvalue  $1+2.7+^{2}.73=(3.^{2}N.)$  of above matrix dominates the scaling of M  $^{+}$ . The dominant scaling dimension of M  $^{+}$ , denoted by M  $^{+}$ ], is then given by

$$M^{+}] = 2 \frac{2 + 7 + 73}{3^{2}N} 2 \frac{31:1}{3^{2}N}$$
: (115)

The decay exponent of the correlation function results im m ediately:

$$\text{IM} (x) \quad \text{M} \left( \frac{1}{\dot{y}} \times x^0 f^{M+1} + \frac{1}{y} \right)$$
 (116)

where the ellipsis denotes the decay with the larger exponent coming from the other eigenvalue of the matrix in Eq. (114).

Finally, we mention a comparison between our result and the Rantner (W en studies. 12 They studied spin correlations in their large-N QED3 e ective eld theory in the Landau gauge. They were interested in the similar bilinear form as we have here with M = 1. In our calculation any bilinear form with the property [M;]=0has the same scaling dimension. To check our result we turned o all contributions to the exponent coming from term s involving . The result  $M^{+}$   $_{\rm ASL}$  = 2 32=(3  $^{2}{\rm N}$  ) obtained in Feynm an gauge agrees with theirs obtained in Landau gauge. 2 M  $^+$   $_{
m ASL}$  corresponds to the decay exponent of localized spin correlation when we are in the ASL phase, where the Kondo eld is massive. As expected, we have  $M^+$   $_{ASL}$  <  $M^+$   $_{J}$ , i.e. the Neel uctuations are stronger in the ASL phase than at the KI transition, where the K ondo singlets are form ing.

In the J <  $J_{K}^{\rm cr}$  regim e the ASL is in the presence of the sem i-m etal (described by eld) and the gapped K ondo eld b. The question m ay arise whether the sem i-m etal would destabilize the ASL. The sem i-m etal will not destabilize the ASL, because integrating out and belds in this phase will produce (retarded) four-ferm ion interaction term among elds. These four-ferm ion teractions are irrelevant at the ASL xed point.

### VI. STABILITY OF THE FIXED POINT

In this section we discuss the issue of the stability of the K I{ASL xed point in the honeycomb lattice to 1st order in 1=N. There are two separate issues one has to consider in the stability of this xed point.

In going to the continuum lim it we have dropped the compact character of the gauge eld. This is only justied if the instanton events, where the ux of the gaque eld suddenly changes by 2 , do not proliferate. For  $J_K > J_K^{cr}$  the Kondo eld b is condensed and we are in the Higgs phase. Gauge eld is massive, its uctuations are supperessed and instantons do not proliferate. Addressing the proliferation of instantons in the regim e where the K ondo phase has disappeared is more subtle. We know from Polyakov's work that the compact pure gauge theory in 2+1 dim ension is in the con ning phase for all coupling constant, i.e. for all coupling constants the instantons proliferate. 21 It has been argued recently that coupling the gauge eld to massless Dirac elds results in a decon ned phase for su ciently large N. 13 This is due to the fact that the massless matter eld, in this case Dirac elds, suppress the uctuations of the gauge eld. We apply that argument here and assume that the

gauge eld in the  $J_K$  <  $J_K^{\rm cr}$  regime is in a decon ned phase. At the K I{ASL} xed point, due to the presence of an extra massless matter eld, i.e. the K ondo eld b, the gauge eld uctuations are suppressed even more.

Next we focus on the instanton { free sector. At the xed point the gauge eld a , boson b and two ferm ion leds , ; all have scaling dimension 1+0 (1=N). This can be seen by the form of propagators derived in Sec. IV. The large N scaling dimension of a , b, and will limit our choices for relevant perturbations. Dierent such perturbations are discussed below:

b m ass term: this term is already present in the microscopic bare Lagrangian. We have to tune  $J_K$  to make the elective mass of the beld to be zero. This perturbation is indeed relevant.

and m ass term s: these m ass term s either break the SU (N) avor sym m etry or the particle-hole and rotation sym m etry.

bkinetic term of the form b (@ + ia) b: this term violates the particle (hole symmetry. It has to be accompanied by b (@ ia) b with an equal coe cient. But b @ b + b@ b = @ (b b) is a total derivative.

b kinetic term of the form L = N gj(@+ ia) bf: this term is irrelevant by the power counting. That is

$$\frac{dg}{dl} = 1 + O (1=N) g:$$

K inetic terms for and elds: these are the only potentially dangerous perturbations, because they are marginal in the N ! 1 limit. A ctually in the derivation of the Lagrangian density Eq. (61) we set  $v_{\rm c}=v_{\rm f}$  to make the action Lorentz invariant. We have to consider perturbations that break this \tuned" Lorentz symmetry and study their ow. By scaling argument the ow of these perturbations is marginal to rst order in 1=N: marginally irrelevant, relevant, or exactly marginal. Our calculations results in the marginal irrelevance of these types of perturbations. We discuss this issue below.

 $\ensuremath{\mathtt{W}}$  e break the Lorentz sym m etry by adding the perturbation

to the Lagrangian density. The perturbation has to be considered both in and elds because of their mixing due to the exchange of the beld. Applying Callan-Symanzik equation to the propagators

and a a results in the following RG ow:

where the matrix anomalous dimension D is given by

$$D = \frac{1}{15^{2}N} \begin{cases} 2 & 74 & 32 & 32 & 2 & 4 & \frac{3}{4} \\ 6 & 32 & 74 & 32 & 4 & 2 & \frac{7}{4} \\ 6 & 32 & 32 & 74 & 4 & 4 & \frac{7}{2} \\ 2 & 4 & 4 & 10 & 0 & 0 \\ 4 & 4 & 2 & 4 & 0 & 10 & 0 \\ 4 & 4 & 2 & 0 & 0 & 10 \end{cases}$$
 (118)

E igenvalues of this matrix anomalous dimension are all negative except for one trivial zero eigenvalue. The zero eigenvalue is trivial since the corresponding perturbation can be absorbed by scaling and elds, shown in Appendix A.

We knew from the mean-eld result that there exist a xed point in the parameter space. But our results goes further by ruling out a multi(critical xed point. So based on our result, for large enough N , this quantum critical point will be achieved by tuning one parameter  $J_{\rm K}$  .

### VII. CONCLUSIONS

We have studied the Kondo {Heisenberg model on the honeycomb lattice at half lling. The main motivation for our study is that the Kondo band gap vanishes at a nite Kondo coupling constant (even as  $J_{\rm H}$ ! 0) so that a novel kind of quantum phase transition becomes possible.

In this paper we considered the transition of this K ondo insulator (K I) to a spin liquid phase which is later identi ed to be algebraic spin liquid (A SL). We developed a mean-eld theory for such a transition using a ferm ionic representation for spins. To consider uctuations about this mean-eld system atically, we adopted a large N generalization of our model by having N spin-avors rather than just f"; #g. We found that the K I{A SL transition is controlled by a stable Lorentz invariant xed point.

In the KI phase, the Kondo eld b condenses and we are in the Higgs phase where the gauge eld is massive. A SL phase is described by \decoupled" QED  $_3$  (coming from  $J_{\rm H}$  S  $_{\rm i}$  S interaction) and the Dirac conduction electrons. They are \decoupled" in that the Kondo eld that couples these two terms is now massive. The gauge eld is deconned in the ASL.

We were able to calculate the exponent =  $1 + 16 = (3^{2}N)$  of the diverging length scale near the transition. Interestingly, 1=N uctuations have pushed the in nite N result further away from the result = 1=2

one would get from the Landau-type expansion. We noted that at our xed point the quasi-particle weight of the conduction electron vanishes which is indicative of non-Ferm i liquid behavior. We also calculated the decay exponent of the staggered spin  $M = S_A$ correlation at the xed point. This is not a scaling operator, since it mixes with  $m = s_A$ dom inant decay exponent turned out to be 2 M + ] =  $47 + 73 = (3^{2}N)$  $62.2=(3^2N)$ . On the 4 other hand, in the ASL phase M is a scaling operator with the decay exponent  $2 M^{+}_{ASL} = 4 64 = (3^{2}N)$ . The jump in this exponent, as one gets to the KI transition point, is due to the fact that there exists an extra massless matter eld at the transition (in this case K ondo eld b), which modi es the exponent. This jum p and its signi cance was discussed in a dierent context recently.18

The quantum phase transition between the KI and ASL does not break any physical symmetry. The KI ASL transition is essentially a Higgs (decon nement transition. In other words, what changes at the transition point is the dynamics of the gauge eld. This by itself is an interesting property of the transition we have studied, which is realized in a minimal Kondo (Heisenberg model.

In connection to this work, we are currently pursuing the num erical study of this m odel; using a quantum M onte C arb technique w ithout the ferm ion sign problem .

### VIII. ACKNOW LEDGMENTS

We thank Michael Hermele for many insightful comments and suggestions and we thank T. Senthil and X.—G.W en for helpful discussions. PAL acknowledges the support by the Department of Energy under grant DE—FG 02-03ER 46076.

## APPENDIX A:RESTORATION OF THE LORENTZ INVARIANCE

Here we will give more details regarding the irrelavance of the perturbations that break the Lorentz sym metry at our Lorentz invariant KI{ASL xed point. It is tempting to break the Lorentz invariance by perturbing only one eld, or . However and loose their own identity as b becomes massless and they mix together. Having this mixing in mind we consider the most general perturbation which is of the kinetic form for the and elds, and is consistent with the gauge symmetry

$$L_{E}^{a} = X$$
 $a = 0 \quad a + a \quad (0 \quad ia) \quad a :$ 
(A.1)

The corrections to ferm ion propagators and gauge vortex is represented diagram m atically:

where we have used the notation

We evaluate the two propagators and and and in the presence of the perturbation given by Eq. (A1).

Next we calculate a which is given by

### a a is given by

where the sum over the space{time index , appearing in the above diagrams, is understood. Calculation of the diagrams  $\mid$  done in Feynm an gauge  $\mid$  results in:

a a 
$$(k) = k^{-1} 1 + \frac{2}{3^{-2}N} \log(k)$$
  $(k) = k^{-1} 1 + \frac{2}{3^{-2}N} \log(k)$   $(k) = k^{-1} 1 + \frac{\log(k) = k}{15^{-2}N}$   $(k) = k^{-1} 1 + \frac{\log(k) + \log(k)}{15^{-2}N}$   $(k) = k^{-1} 1 + \frac{$ 

where S; is given by

$$S : = 20 + 2 + 4 + 4 : (A 6)$$

The above propagator has a contribution from the unperturbed xed-point action, which gives the gauge independent scaling dimension for eld

$$= 1 + \frac{1}{3^{2}N} :$$
 (A7)

W e obtain

a a (k) = 
$$\frac{1}{k} + \frac{2}{2N} \log(jk = 1)$$
  
+  $jk + k = 1$  +  $\frac{\log(jk = 1)}{15^2N} = jF$ ; (A.9)

where F; is given by

$$F := 104$$
 32 32 + 2 + 4 + 4 : (A 10)

From Eq. (A9), we obtain the scaling dimension of the eld in Feynm an gauge:

$$= 1 + \frac{1}{2_{\text{N}}}$$
: (A 11)

Then we use the Callan-Sym anzik equation machinery by scaling the momentum  $k \,! \, e \, k$  and applying

$$\frac{\theta}{\theta'} + (3 \quad 2 \quad) + \frac{dC_m}{d'} \frac{\theta}{\theta C_m} \qquad a \quad a = 0; \quad (A 12)$$

$$\frac{\theta}{\theta'} + (3 \quad 2 \quad) + \frac{dC_m}{d'} \frac{\theta}{\theta C_m} \qquad a \quad a = 0; \quad (A 13)$$

where the set  ${\tt C}$  includes the coupling constants that ow . For the perturbation under consideration it has 6 elements:

$$C = f_{0;1;2;0;1;2}q$$
:

Eqs. (A12), and (A13) will lead to the RG ow:

$$\frac{e}{e} \begin{cases}
6 & 17 \\
6 & 27 \\
6 & 27
\end{cases} = D \begin{cases}
6 & 17 \\
6 & 27 \\
6 & 07
\end{cases};$$
(A 14)

where the matrix anomalous dimension D is given by

$$D = \frac{1}{15^{2}N} \begin{cases} 2 & 74 & 32 & 32 & 2 & 4 & \frac{3}{4} \\ 6 & 32 & 74 & 32 & 4 & 2 & \frac{7}{4} \\ 6 & 32 & 32 & 74 & 4 & 4 & \frac{7}{2} \\ 4 & 2 & 4 & 4 & 10 & 0 & 0 \\ 4 & 4 & 2 & 4 & 0 & 10 & 0 \\ 4 & 4 & 2 & 0 & 0 & 10 \end{cases}$$
 (A 15)

All the eigenvalues of this matrix anomalous dimension is nonpositive. There is one zero eigenvalue with the corresponding eigenvector

The above shift can be absorbed by scaling and elds separately. The scaling is delicate, since in our RG scheme we have xed the coe cient of b a + cr: to be 1. So the scaling of and has to be accompanied by an appropriate scaling of b. But this - in general will move us away from the critical point. For the above perturbation though, the scaling factor for b is 1:

$$\frac{1}{1} = 1 + 0 (^{2})$$
:

So the above perturbation remains exactly marginal to allorders in 1=N.

It is interesting to note that the uniform shift

is an eigenvector with a negative eigenvalue. Why should this perturbation ow? The absorbtion of the uniform perturbation in and has to be accompanied by scaling the beld by

$$\frac{1}{1+\frac{1}{1+}} = 1 + 0 (^{2})$$
: (A 16)

This scaling of the b eld will move us away from the critical point.

In this appendix we will not the algebraic decay exponent of hM (x) M (x) is at K I(ASL xed point. We do this by obtaining the staggered spin M scaling dimension. It suces to not the scaling dimension of M  $^+$ , since the decay exponent of hM (x) M (x) is the same. The rst step is to translate M  $^+$  to the eld theory language with the dictionary provided by Eq. 53. The expanded form is given by

Start with the expression for  $S_A^+ = S_A^1 + i S_A^2 = f_A^{1y} f_A^2$  , which leads to

$$S_{A}^{+}(x) = {}^{1}(x) {}^{B}_{A} {}^{0} {}^{0} {}^{0} {}^{C}_{A} {}^{2}(x);$$
 (B3)

The sim ilar translation can be done for  $S_{\rm B}^+$  . The nal and  $^{1}$   $^2$  is then given by: result is:

$$M^{+}(x) = {}^{1}(x)M^{-2}(x);$$
 (B4)

where M is

$$M = \frac{0}{8} \quad 1 \quad C = 1 \quad 3:$$
 (B 5)

The matrix M has the following properties:

$$[M ; ] = 0;$$
 (B 6)

$$Tr M = 0; (B7)$$

where is a generic notation representing any number of matrices multiplied. The 1st property is useful since M passes through all the matrices and the nal result for the propagatros  $\begin{bmatrix} 1 & 2 \\ i & j \end{bmatrix}$  and  $\begin{bmatrix} 1 & 2 \\ i & j \end{bmatrix}$  will have a simple matrix form k M k . The second property causes any diagram, with matrix M left in a loop, to vanish.

The scaling dimension of M  $^+$  is obtained by looking at its relevant ow near the xed point. Due to mixing we perturb the Lagrangian density by

$$L_E = U_+$$
  $^1 (x)M$   $^2 (x) + U_+$   $^1 (x)M$   $^2 (x);$  (B8)

and study the Callan-Sym anzik equation for the propagators  $^{\ 1}$   $^{\ 2}$  and  $^{\ 1}$   $^{\ 2}$  .

The vertices corresponding to these perturbations are represented by

The diagram matic expression for propagators

The nalanswers in the Feynm an gauge are as follows:

$$^{1} {}^{2} (k) = * {}^{1}M * {}^{1} U_{+} 1 \frac{8}{{}^{2}N} \log(k) + \frac{2u_{+}}{{}^{2}N} \log(k) :$$
 (B13)

Then we use the Callan-Sym anzik equation by scaling the momentum  $k \,! \, e \, \hat{k}$  and applying

$$\frac{\theta}{\theta'} + (3 \quad 2 \quad) + \frac{dC_m}{d'} \frac{\theta}{\theta C_m} \qquad ^{1 \quad 2} = 0$$

$$\frac{\theta}{\theta'} + (3 \quad 2 \quad) + \frac{dC_m}{d'} \frac{\theta}{\theta C_m} \qquad ^{1 \quad 2} = 0$$
(B14)

The set C includes the coupling constants that ow. For the perturbation under consideration it has two elements:

$$C = fU_+; u_+ q:$$

The above Callan-Sym anzik equations leads to the following RG  $\,$  ow:
