Filling-dependence of the zigzag H ubbard ladder for a quasi-one-dim ensional superconductor P $r_2B\,a_4C\,u_7O_{15}$

Kouichi O kunishi

Department of Physics, Faculty of Science, Niigata University, Igarashi 2, 950-2181, Japan (Dated: March 23, 2024)

W e investigate lling dependence of the zigzag H ubbard ladder, using density m atrix renorm alization group m ethod. W e illustrate the chem ical-potential vs. electron-density and spin gap vs. electron density curves, which re ect characteristic properties of the electron state. On the basis of the obtained phase diagram, we discuss the connection to a novel quasi-one-dimensional superconductor $\Pr_2 Ba_4 C u_7 O_{15}$.

I. IN TRODUCTION

Low-dimensional strongly-correlated-electron systems have been one of the most active research elds in the condensed matter physics, since the discovery of high- T_{c} superconductivity.¹ One of the current topics in the eld is the frustration e ect, which often causes a variety of interesting behavior such as exotic superconductivity. Recently, a novel quasi-one-dimensional(1D) compound $Pr_2Ba_4Cu_7O_{15}$ (Pr247) was found to exhibit the superconductivity below T_c ' 18K. This compound has the layered structure of single chains, frustrated zigzag ladders, and CuO₂ planes.^{2,3} An important point on Pr247 is that the metallic conductivity originates from the zigzag ladder part, while the CuO₂ plane is insulating with the antiferrom agnetic order below 285K .4,5,6 M oreover the oxygen atoms at the single chains, which are also insulating, are easily defected with the deoxidization and then the electrons are e ectively doped into the zigzag ladders from the single chain sites. This suggests that Pr247 can be regarded as a natural \ lling controlled system ", which hopefully provides an interesting physics cooperatively induced by the lling dependence and the frustration e ect. In fact, the transition tem perature of Pr247 exhibits the system atical relation to the oxygen deciency, implying that the electron-lling plays a crucial role for appearance of the superconductivity.

A relevant m odel describing P r247 is the zigzag H ubbard ladder, whose H am iltonian is given by

$$H = \bigcup_{i}^{X} [t_{1}c_{i}^{y}c_{i+1} + t_{2}c_{i}^{y}c_{i+2} + hc:] + U \bigcup_{i}^{X} n_{i}n_{i};(1)$$

where c_i is the electron annihilation operator at i site with spin and n_i $c_i^y c_i$.⁷ $t_1 (t_2)$ is the nearest (nextnearest) hopping term of the electron and U is the on site coulom b energy. We also introduce = $t_1=t_2$ j for later convenience. A coording to Ref.⁷, the overlap of Cu-3d orbit and O-2p orbit in the zigzag array of Cu-O double chain structure suggests that the parameters corresponding to Pr247 are in $t_2 < 0$ and < 1. We also assume U = $8t_2$ j or $8t_1$ j which m ay be of sim ilar order to the usual cuprates. The lling of the zigzag ladder part in Pr247 of = 0 corresponds to the nearly quarter lling.⁵ As the oxygen de ciency increases, it rises continuously toward half-lled side and the superconductivity appears for > 0.3. This indicates that it is primarily important to investigate the frustration and lling dependences of the electron state system atically, for through understanding of the Pr247 superconductivity.

The Hamiltonian (1) is a typical example of the 1D correlated electron system capturing various frustration e ects. Indeed, interesting properties of low energy excitations are revealed at the half-lling or quarter 11ing by extensive studies with bosonization and various num ericalm ethods.^{8,9,10,11,12,13,14} In particular, Fabrizio sketched the qualitative phase diagram 8 by invoking the weak coupling theory for the non-frustrating ladder system¹⁵, and D auletalpresented an approxim ate phase diagram in the context of the ferrom agnetism ¹⁰, which also reveal that the zigzag H ubbard m odel contains quite rich physics. However, both the frustration and the incom m ensurate Ferm i wave num ber m ake a quantitative analysis of the low -energy excitations subtle; the precise lling-dependence of the spin gap is still unclear in the relevant param eter region to Pr247.

In this paper, we precisely investigate the lling dependence of the zigzag Hubbard ladder with intensive calculations of density matrix renormalization group (DMRG)¹⁶. In the next section we particulary illustrate the chemical potential-electron density (-) curve. In section III, we investigate the lling dependence of the spin gap in the region $t_2 < 0$, from which we read characteristic properties of the electron state . In sections IV and V, we summarize the DMRG results as a phase diagram and then discuss the relevance to the superconductivity in Pr247 respectively. Here, we note that the convergence of DMRG computation in the single band region is good with a relatively sm all number of retained bases m 200, while in the two band region, we can obtain the reliable spin gap with up to m = 1000.

II. - CURVES

Let us write the gourd state energy of L sites as E_{L} (N;S^z), where N denotes the number of electrons and

 $S^{\,z}$ indicates the total-S z of the system . The electron density is written as N =L and then the chem icalpotential is de ned as = $[E_{L}(N + 1; 1=2) \quad E_{L}(N; 0)]$ for N = even or = $E_{L} (N + 1;0) = E_{L} (N;1=2)$ for N = odd. This de nition of should be contrasted to the conventional notation of even number of electrons. This is because the - curve of the present de nition of can visualize som e in portant natures of the low -energy excitation; If the charge excitation is gapless, the - curve acquires a smooth stairway-like curve. If two electrons conform a bound state, the N = even case is slightly stable than the N = odd case, due to the binding energy of the electrons. This suggests that if the system has the bound state, the - curve exhibits overhung behavior. W e should note that the sim ilar behavior can be actually seen in the magnetization curve of the zigzag spin system .17

A s can be expected, the basic property of the - curve is attributed to the one-particle dispersion curve that is easily obtained as

"(k) =
$$2t_1 \cos(k) + 2t_2 \cos(2k)$$
: (2)

The shape of this dispersion curve has double-well form for < 4 (recall the sign of t_2 is negative), where it has the van Hove singularity. In the following, the corresponding electron density is denoted as _c. As increases, _c comes down to the lower-electron density region. For < 2, _c reaches below the half lling (< 1), and, at = 1=2, it is located near the quarter lling. As ! 0, the system nally becomes the two decoupled Hubbard chains. Thus the system in the noninteracting lim it (U = 0) is essentially a single band system for < _c, while it is a two band system having four Ferm i points for > _c. We note that a nite U may induce the spin gap in the two band region, according to the weak coupling theory.

In Fig. 1, we show the - curves of U = 8 for = 1 and = 0.5 with t_2 = 1. In the gure, we can nd a characteristic feature: The curvature of the - curve changes at c' 0.73 for = 1 and c' 0.5 for = 0.5, which is basically re ecting the shape of the dispersion curve (2). We however note that these values of c are slightly lifted from the non-interacting case due to the e ect of U. A more interesting point is that the curves actually exhibits the oscillating behavior above c. For = 1, we can see the overhung behavior in c < 1, im plying that the spin gap may exist between c and the half lling. On the other hand, for = 0.5, the oscillation is enhanced above c, but the - curve becom es sm ooth again above ' 0.83 as is indicated by an arrow in Fig.1 (b). This suggests that the spin gap the

= 0.5 m ay appear only near $_{\rm c}$. Here, we should note that the even-odd e ect below $_{\rm c}$ is properly rem oved by the size extrapolation.

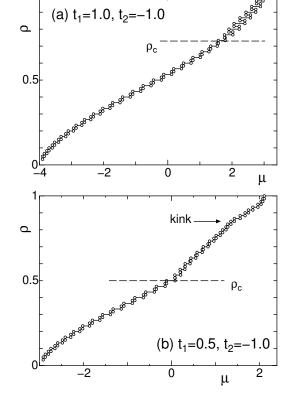

FIG.1: - curves for L = 60 system s of U = 8: (a) $t_1 = 1$ and $t_2 = 1$ (= 1) and (b) $t_1 = 0.5$ and $t_2 = 1$ (= 0.5). The broken lines are guides for $_c$.

III. SP IN G A P

Since we have seen the outline of the lling dependence of the system in the – curve, we further analyze the spin gap for the precise characterization of the low -energy excitation. We denot the spin gap $_{\rm S}$ as

$$_{\rm s}$$
 (N;L) = E_L (N;1) E_L (N;0); (3)

for N = even. In order to extract the bulk behavior of the spin gap, the nite size extrapolation is usually required. We should how ever recall that takes only some fractional values restricted by combination of L and N, as far as we treat a nite size system. In order to avoid this m ism atching problem of the electron lling, we calculate $_{\rm S}$ of all the electron numbers for various L, with which we interpolate the spin gap at an irrational value of . We think that the bulk spin gap can be properly analyzed except for the vicinities of some singular points.

In Fig. 2 (a), we show the DM RG calculated spin gap for L = 48;60;72 with $t_1 = t_2 = 1$ (= 1). We can see that the property of the spin gap clearly changes at $_{c}$ ' 0:7, which is consistent with the - curve. Below $_{c}$, the system is essentially described by the single band and $_{s}$ shows large size dependence, suggesting that the spin excitation is gapless. We thus exam ine the 1=L-size dependence of the interpolated spin gap:

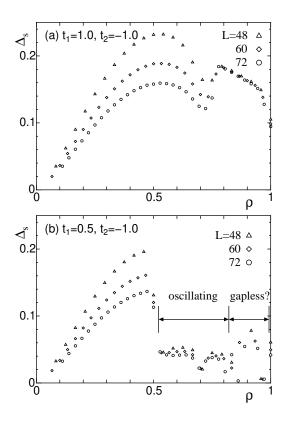

FIG. 2: Size dependence of spin gaps for U = 8: (a) $t_1 = 1$ and $t_2 = 1$ and (b) $t_1 = 0.5$ and $t_2 = 1$.

s(;L) = $_{\rm s}$ () + const=L, and then verify that below _c becomes zero in L! 1. On the other hand, we can expect the spin gap in $_{\rm c}$ < < 1, where the overhung behavior of the - curves is observed. In fact we can clearly see that s is almost independent of the system size, implying that the spin gap remains a nite value in the bulk lim it. Moreover, we can nd that the spin gap is enhanced in < 1 rather than the half-lling, which may be a peculiar behavior in the frustrating system in contrast to the non-frustrating Hubbard ladder. Here, we note that this spin gap phase is adiabatically connected to the dimer spin gap of the corresponding zigzag spin system at the half lling. The amplitude of the spin gap at the half lling is consistent with the zigzag spin chain¹⁸.

Fig. 2 (b) shows $_{\rm s}$ for L = 48, 60, 72 with t₁ = 0.5 and t₂ = 1 (= 0.5). For < $_{\rm c}$ (' 0.5), the system is essentially a single band m odel and thus the size dependence of $_{\rm s}$ is basically the same as that for = 1; the 1=L extrapolation of $_{\rm s}$ leads that the spin excitation is gapless in the therm odynam ic lim it. On the other hand, $_{\rm s}$ above $_{\rm c}$ shows subtle behaviors. Here, we should recall that the - curve for = 0.5 has a weak anom aly at ' 0.83, above which - becomes sm ooth. We rst analyze the region of $_{\rm c}$ < 0.83, for which the evenodd oscillation appears in the - curve. In this region, the spin gap shows oscillating behavior with respect to and . The am plitude of the oscillation increases, as increases from $_{\rm c}$ to 0.83. Thus the precise extrapolation of $_{\rm s}$ is still di cult in this region. However, we note that the size dependence of $_{\rm s}$ in the vicinity of $_{\rm c}$ ($_{\rm c}$ < < 0:7) is rather weak and a sm all spin gap may survive in the bulk lim it.

Next let us turn to 0.83 << 1, where we can see the sim ilar oscillating behavior of s. How ever, this oscillation shows rather system atical behavior depending on N mod 4 = 0 or $\neq 0$. In this region, the system is basically described by the two chains, where the electron c. Since the system has lling is su ciently away from four Ferm ipoints, the N m od 4 = 0 state is stabilized by conforming \closed shell" with respect to the four Ferm i points, while the N mod 4 6 0 state has a \unoccupied orbits", which may generate an anom alous spin excitation.We thus read the bulk behavior of the spin gap from N mod 4 = 0 sectors, which shows large size dependence suggesting that the spin excitation seems to become gapless or very sm all. How ever, the precise estim ation of the spin gap value is also di cult within L = 72.

Here, we make a comment on the boundary elect, since a boundary excitation may appear in the gapped frustrating system with the open boundary. In order to check it, we have also calculated magnetization curve at some typical llings. Then we can verify that the S² = 1 excitation sm oothly connects to the bulk part of the magnetization curve in the spin gap phase of = 1.0 n the other hand, the magnetization curve of = 0.5 suggests that the sometimes sometimes capture the boundary elect in the oscillating spin gap region, where the S² = 1 excitation sometimes generates an anom alous step away from the bulk part of the magnetization curve.

IV. PHASE DIAGRAM

In Fig. 3, we summarize the phase diagram of the zigzag Hubbard model for U = 8, which is determined by the - curves and the spin gap for L = 72. The open circles indicate the boundary between the singleband gapless phase and spin gap/oscillating region, which is slightly lifted from c for the free electron case due to the electron correlation e ect. The \setminus spin gap" indicates the spin gap phase, which is connected to the dim er spin gap phase at the half lling^{9,13}. As decreases from the dim er spin gap phase, the spin gap rapidly decreases and alm ost vanishes across the dotted line. W e also note that spin gap at the half-lling for < 0.7 seems to be alm ost gapless. However, it is still di cult to distinguish whether the spin excitation in this regime is the truly gapless phase or very small spin gap phase within the present accuracy.

In the region $\$ scillating", the behaviors of the spin gap becomes subtle, as in FIG 2 (b). The oscillating behavior of $_{\rm S}$ makes precise analysis of the spin gap in the bulk limit di cult. In the vicinity of $_{\rm C}$, however, we have seen that the size dependence of $_{\rm S}$ is not so large, suggesting the existence of the spin gap, which is relevant

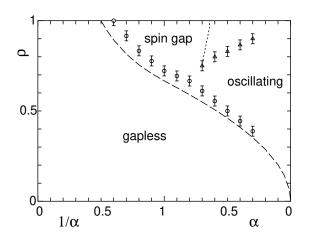

FIG.3: Spin-excitation phase diagram of the zigzag H ubbard ladder of U = 8. In the left-half, $0 < t_2 < 1$ with $t_1 = 1$, and in the right half, $0 < t_1 < 1$ with $t_2 = 1$. O pen circles indicate the boundary between the single-band gapless phase and the spin gap phase. The dotted line is a guide for the vanishing line of the spin gap. Triangles mean the boundary between the (alm ost)gapless region and the oscillating spin gap region. The broken line means $_c$ of the free electron case. The error bar corresponds to the interval of descritized density of electron for a L = 72 system.

to Pr247 (see Sec. V). As increases, the irregular oscillation to becomes signicant and the size extrapolation of s breaks down. The upper bound of the oscillating region is indicated by the open triangles, which are corresponding to the weak kink in the - curve. In order to illustrate another aspect of the oscillating region, we further investigate s as a function of for a xed . Figure 4 shows the -dependence of $_{\rm s}$ for L = 72 and N = 60 (= 0.833). We can then nd that s exhibits the rapid oscillation with respect to for < 0.5, which suggests that the incom m ensurate nature due to the frustration and the boundary e ect cooperatively induce such subtle behavior of s. The rapid increase of $_{\rm s}$ for > 0.8 corresponds to the spin gap phase in Fig. 3. In the intermediate region (0:5 << 0:7) the size dependence of suggests gapless or alm ost gapless spin excitation, as m entioned before.

Here we would like to make a comment on the resolution of the phase diagram within L = 72; For example we can not distinguish whether the boundary between the gapless region and the oscillating region/spin gap phase (open triangles/dotted line in Fig.3) is a bulk phase transition or not, this y because of the limited system size. Also such a narrow phase as C 2S2 mentioned by the weak coupling theory⁸ is beyond the resolution of the discretized density of the electron. In addition, we note that the spin gap for < 0.3 is not evaluated properly within the DM RG calculation, since the energy scale of the spin gap itself becomes too sm all in the decoupled chains limit.

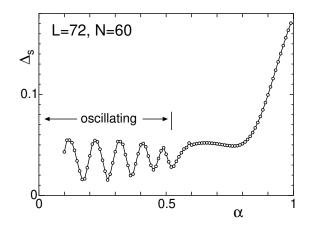

FIG.4: -dependence of the spin gap $_{\rm S}$ of the zigzag Hubbard model for L = 72 and N = 60(= 0.833). The on-site Coulomb interaction is xed at U = 8. In > 0:7 (corresponding to the dotted line in FIG.3), the system is in the spin gap phase. In < 0.5, $_{\rm S}$ shows the rapid oscillation with respect to .

V. DISCUSSIONS

On the basis of the phase diagram , let us discuss the lling dependence of Pr247. As was discussed in Ref.⁷, the chemical potential shifts from the quarter lling toward the electron doping side by oxygen reduction. If assuming that T_c is proportional to the amplitude of the spin gap in the zigzag ladder, we can see that the e ective modelparameter of Pr247 is most likely in ' 0:5 0:7, for which the dependence of T_c basically agrees with the lling dependence of the spin gap³. Thus, Pr247may be located near the most competing region in the phase diagram where the spin gap shows the subtle behavior, which is consistent with the relatively low T_c of Pr247. In addition, it is suggested that Pr247 is sensitive to modication of parameters due to external elds such as high pressure e ect.¹⁹ As con m ed in the NQR/NMR experiments⁶, a good one-dimensionality can be expected for Pr247 due to the superstructure of the m etallic zigzag ladders, the insulating single chains and CuO_2 planes. Such superstructure m ight be related to the relatively large , compared with a similar ladder com pound Y B a_2 C u_4 O $_8$. Very recently, N akano et al have made FLEX calculation on the basis of the band structure of YBa₂Cu₄O₈, which nevertheless suggests the swave superconductivity in the small region²⁰. Thus the consistency with the actual band structure of Pr247, which is not available now experimentally and theoretically, is highly interesting.

In this paper, we have clari ed the various interesting behaviors induced by the frustration e ect in the phase diagram. In particular, the enhancement of the spin gap above $_{\rm c}$ and the appearance of the oscillating region may be essential in the connection with the Pr247 experiments. However, we did not mention the correlation functions and the pairing symmetry here, which has been

still unknown experimentally. In order to determ ine the paring symmetry, it is needed to precisely investigate the correlation functions for a su cient long chain. Also the U-dependence of the zigzag Hubbard model, e.g. the connections to the t-J model and the weak coupling theory, is a theoretically in portant problem. We hope the present work to be a portal of further researches on the Pr247 superconductivity from both theoretical and experimental view points.
