<sup>(3)</sup> LD. Landau Institute for Theoretical Physics, Moscow, Russia

We propose a uni ed magnetic phase diagram of cuprate superconductors. A new feature of this phase diagram is a broad interm ediate doping region of quantum – critical, z = 1, behavior, characterized by tem perature independent  $T_1T=T_{2G}$  and linear  $T_1T$ , where the spin waves are not completely absorbed by the electron-hole continuum. The spin gap in the moderately doped materials is related to the suppression of the low-energy spectral weight in the quantum disordered, z=1, regime. The crossover to the z=2 regime, where  $T_1T=T_{2G}^2$  const, occurs only in the fully doped materials.

1.Introduction

Recent m easurem ents [1,2,3,4] of the spin-echo decay rate,  $1=T_{2G}$ , for a num ber of cuprate oxides, taken together with earlier m easurem ents of spin-lattice relaxation rate  $1=T_1$ , provide considerable insight into their low frequency spin dynam ics. In this communication we show how these m easurem ents m ay be combined with straightforward scaling argum ents to obtain a uni ed m agnetic phase diagram for the Y – and La-based system s.

In the presence of strong antiferrom agnetic correlations at a wavevector Q, the main contribution to both  $T_1^{1}$  and  $T_{2G}^{1}$  for copper com es from small  $\mathbf{q} = \mathbf{q} - \mathbf{Q}$ , so that one may write [5]:

$$\frac{1}{T_{1}T} = d^{2}\mathbf{q} \lim_{!! 0} \frac{m(\mathbf{q};!)}{!!}; \quad \frac{1}{T_{2G}} = d^{2}\mathbf{q}^{2}(\mathbf{q};0)^{1=2}; \quad (1)$$

where  $(\mathbf{q}; !)$  is the electronic spin susceptibility near Q. On making use of quite straightforward scaling arguments, when applicable, one may substitute  $(\mathbf{q}; !) = {}^{2} \land (\mathbf{q}; ! = !)$ into Eq.(1) ( is the scaling dimension of the real space spin correlator) and obtain:

$$\frac{1}{T_{1}} T ! ^{1}; \frac{1}{T_{2G}} ^{1}; \frac{T_{1}T}{T_{2G}} !: \qquad (2)$$

where is the correlation length and ! an appropriate energy scale.

# 2. A pplicable Scaling R egim es

We consider rst a clean quantum antiferrom agnetic insulator (referred to as \insulator" hereafter), described by the S = 1=2 H eisenberg m odel with the exchange coupling J. Because the spin sti ness, s' 0:18J [6], is small compared to J, the quantum -critical (QC) scaling regime [7], where the only energy scale is set by temperature, ! T, exists over a substantial temperature range 2 s < T < J [8,9]. The dynam ical exponent, z, which relates the characteristic energy and length scales according to ! <sup>z</sup>, is z = 1 as a consequence of Lorentz invariance at T = 0, rejected in the linear dispersion relation of the spin waves. In this case, T<sub>1</sub>T=T<sub>2G</sub> ! <sup>1 z</sup> const. Since ! <sup>1=z</sup> T <sup>1=z</sup> T <sup>1=z</sup> T <sup>1</sup>, one further obtains

1=T<sub>1</sub> T<sup>z</sup> T [9] and 1=T<sub>2G</sub> <sup>1</sup> T<sup>1</sup>; because the critical exponent is negligible, 1=T<sub>1</sub>' const, while 1=T<sub>2G</sub> T<sup>1</sup>.

A second regin e of interest is the two-dimensional renormalized classical (RC) regine,  $T_N < T < 2_s$ , which is characterized by an exponential increase of the correlation length and relaxation rates. In the dynam ical scaling theory of Chakravarty, H alperin, and N elson [7], 1=T<sub>1</sub> T<sup>3=2</sup> exp (2<sub>s</sub>=T) and 1=T<sub>2G</sub> T exp (2<sub>s</sub>=T). The prefactors arising from the log corrections lead to a power-law temperature dependence of the ratio  $T_1T = T_{2G}$  T<sup>1=2</sup>, while z = 1 leads to the cancellation of the leading (exponential) term s.

According to numerical calculations for the insulator in the 2D S = 1=2 Heisenberg model [10,11], as long as T < J, the damping, q, of the high energy (!  $_{q}$  > c  $^{-1}$ ) spin wave excitations, is small throughout the Brillouin zone; hence, for both RC and QC regimes those can be treated as good eigenstates of the model. The dynamical susceptibility can then be well approximated as:

$$(q;!) = _{q} \frac{1}{! ! ! _{q} + i_{q}} \frac{1}{! + ! _{q} + i_{q}} ;$$
 (3)

except near the origin, where the dynam ics is di usive as a consequence of total spin conservation, and near the N eel ordering vector, Q = (=a; =a), where it is relaxational; for  $1 < q < a^{-1}$ , the expression (3) is valid in both QC and RC regimes, where  $_{q}$  1=q and  $!_{q}$  ' cq. A coording to R ef. [12], the one-m agnon neutron scattering intensity in the insulator is indeed well described by Eq.(3) with  $_{q}$  !<sub>q</sub>.

It has been conjectured in Ref. [9] that the small doping as well as random ness related to it are not likely to a ect the universal scaling behavior at high temperatures. Quite generally, one would expect a departure from z = 1 behavior only when spin waves become overdam ped by the electron-hole continuum [13]. Since this would require a substantial increase in spin wave damping, to  $_{q} > !_{q}$ , compared to its insulator value,  $_{q}$  ! $_{q}$ , there m ay be an intermediate regime in which the spin waves are not yet absorbed by the electronhole continuum, even if the damping is increased compared to the insulator. To the extent this occurs, the system can remain in the QC regime with z = 1 in a wide range of doping and tem peratures due to the Lorentz invariant term s in the action.

In the insulator, the zero temperature energy gap = hc= for the spin-1 excitations in a quantum disordered (QD) regime is, again, related to the Lorentz invariance at T = 0 [7]. Hence, as long as the Lorentz invariant terms in the action are still in portant and the correlation length saturates, the low frequency (! < ) spectral weight could be suppressed even in a metal. We suggest that the spin gap phenomenon in YBa<sub>2</sub>Cu<sub>3</sub>O<sub>6:63</sub> and YBa<sub>2</sub>Cu<sub>4</sub>O<sub>8</sub>, characterized by a sharp increase in T<sub>1</sub>T and decrease of the bulk susceptibility, is related to this suppression, and this phase corresponds to a QD, z = 1, regime.

At larger hole densities, the spin waves will be fully damped by the electron-hole continuum. In this regime, the self-consistent renorm alization (SCR) approach developed by Moriya et al. [14] (see also Ref. [13]) and the phenomenological theory of Millis et al. [15], for YBa<sub>2</sub>Cu<sub>3</sub>O<sub>7</sub> may be expected to apply. The dynamical exponent z = 2, while = 0; in contrast with the previous case, the mean eld exponent z = 2 is not xed by a symmetry, but rather follows from the scaling analysis of Ref. [14,13]. One obtains  $T_1T = T_{2G}^2$  ! <sup>2</sup> <sup>2</sup> <sup>z</sup> <sup>'</sup> const, while  $T_1T = T_{2G}$  <sup>1</sup>. At high tem peratures, the energy scale T, so that  $!^{1=z}$  T  $!^{1=z}$  T  $!^{1=z}$ , in which case  $T_1T=T_{2G}$   $T^{1=2}$ , and, separately, ! 1=T<sub>1</sub> T<sup>z</sup> const, 1=T<sub>2G</sub> T<sup>1=2</sup>. We emphasize that 1=T<sub>1</sub> const at high temperatures is predicted for both z = 1 and z = 2 regimes, while predictions for  $1=T_{2G}$  are dimensional event. Finally, at still larger hole densities, the short range AF correlations between spins will tend to disappear; in this lim it, < a is independent of tem perature, and one recovers the Korringa law,  $1=T_1$  T, while  $1=T_{2G}$  ' const. This regime corresponds to a norm alm etal, in which any remaining antiferrom agnetic correlations can be described by a tem perature independent  $F^{a}(p;p^{0})$ .

# 3. La<sub>2 x</sub>Sr<sub>x</sub>CuO<sub>4</sub>

We rst consider  $La_2 _x Sr_x CuO_4$ . The insulator,  $La_2 CuO_4$ , is well described by the 2D Heisenberg model with the nearest-neighbor exchange coupling J ' 1500K, except near or below  $T_N$  300 K induced by weak interplanar coupling [16]. A nearly temperature

independent  $1=T_1$  is observed in the insulating La<sub>2</sub>CuO<sub>4</sub> above 650K [2], as expected in the QC, z = 1, regime [9]. The absolute value of  $1=T_1$  ' 2700 sec <sup>1</sup> at high temperatures [2] is in very good agreement with both 1=N expansion [9] and nite cluster [11] calculations for the Heisenberg model. Further, the ratio  $T_1T=T_{2G}$  measured in the insulator [2,4] is nearly temperature independent in the broad range 450 K < T < 900 K (Fig.2). This is again what one would expect in the QC, z = 1, regime; we note that this behavior holds even in the region below 650 K, where  $1=T_1$  and  $T=T_{2G}$  separately deviate from constant values, apparently because  $T_1T=T_{2G}$  is insensitive to the magnitude of (q;!).

A nite cluster calculation in the S = 1=2 2D H eisenberg m odel by E.G agliano, S.B acci, and one of the authors (A.S.) (R ef. [11] and this work), with no adjustable parameters used (hyper ne and exchange couplings were determined from other experiments, see R ef. [11]), indeed yields a nearly temperature independent  $T_1T=T_{2G}$  ' 4:3  $1^3$  (K  $^1$  for T > J=2' 750K (Fig 2), in excellent agreement with the experimental result, 4:5  $1^3$  (K [2]). The systematic error of the nite cluster calculation, arising from the periodic boundary conditions as well as spin di usion contribution to 1=T<sub>1</sub>, is estimated in R ef. [11] as 10 15%.

An especially striking feature of the  $1=T_1$  data [2] is the nearly doping independent absolute value of  $1=T_1$  in the high temperature limit (Fig.2). This result shows that not only universal, but also nonuniversal scaling constants are not strongly renormalized in the doping range x = 0 0.15, i.e. up to the optimal concentration for the superconductivity. Since it would be rather unrealistic to assume that exactly the same value can be obtained in di erent pictures of magnetism for low – and high-doped La-based materials, we suggest that the high temperature magnetic behavior over this entire doping range has the same explosed origin as that found for the insulating state, which implies z = 1. As the doping increases, Im ai, Slichter, and collaborators [2] nd that the range of temperatures where  $T_1T$  is linear in temperature stretches towards lower temperatures, from 650K for x = 0 down to 125K for x = 0.15 (see Fig.2). This is the behavior expected if doping leads to a decrease in  $_s$ , thus extending the QC region [9]. We thus conclude that  $La_{1.85}Sr_{0.15}CuO_4$  is in the quantum -critical, z = 1, regime for T > 125K.

A sit is evident from Fig.2 (inset), for T < 125K,  $T_1T$  begins to depart from its linear in T behavior, exhibiting an uptum for T 60 70 K. We attribute this e ect to the suppression of the low frequency spectral weight in the quantum disordered, z = 1, regime [17]. At low er doping values, experiment shows that the low temperature phase is not a superconductor but rather a spin glass, in agreement with the scaling analysis [8], while for the low est doping, the low temperature phase is the antiferrom agnetic N eel state.

### 4. Y B $a_2$ C $u_3$ O $_{6:63}$ and Y B $a_2$ C $u_4$ O $_8$

 $Y B a_2 C u_3 O_{6:63}$  and  $Y B a_2 C u_4 O_8$  have quite similar properties. The product  $T_1 T$  measured in YBa<sub>2</sub>Cu<sub>3</sub>O<sub>6.63</sub> [18,3], is linear in temperature for 160K < T < 300K, while it exhibits sim ilar behavior in YBa<sub>2</sub>Cu<sub>4</sub>O<sub>8</sub> for 170K < T < 800K. Since a linear T<sub>1</sub>T is predicted in both quantum -critical (z = 1) and overdam ped (z = 2) regimes at high tem peratures, to distinguish between these regimes, we turn to the  $1=T_{2G}$  data on YB a<sub>2</sub>C u<sub>3</sub>O <sub>6.63</sub> [3], and plot  $T_1T=T_{2G}$  and  $T_1T = T_{2G}$  as a function of tem perature (Fig.3). In the range 200K < T < 300K,  $T_1T = T_{2G}$  is nearly constant, while  $T_1T = T_{2G}^2$  varies signi cantly, in agreem ent with the prediction for z = 1. W ere thism aterial in the z = 2 regime,  $T_1 T = T_{2G}$  would increase as the tem perature increases, while  $T_1T = T_{2G}^2$  would be constant. We thus conclude that above 200K, YBa<sub>2</sub>Cu<sub>3</sub>O<sub>6:63</sub>, and the closely related YB  $a_2$ C  $u_4$ O  $_8$ , are in the QC, z = 1, regime. The increase in damping in the doped case, which enhances  $1=T_1$  with respect to  $1=T_{2G}$ , may explain the smaller (compared to the insulating  $La_2CuO_4$ , Fig.2) saturation value of  $T_1T=T_{2G}$  in those compounds. Our scenario may seem to contradict the Ram an studies in YBa<sub>2</sub>Cu<sub>3</sub>O<sub>6+x</sub>, because two-magnon R am an scattering is not observed for doping above 0 6:4 [19]. How ever, this contradiction is illusory, since the decrease of intensity in the two-m agnon R am an scattering is prim arily due to the loss of the charge-transfer states rather than any change in the short range m agnetic correlations [19,20].

For tem peratures below 150 K,  $1=T_1$  sharply drops down as the tem perature decreases, while  $1=T_{26}$  [18,3] saturates. As was the case for  $La_{1.85}Sr_{0.15}CuO_4$ , we argue this suppression of the low frequency spectral weight (spin gap) relects a crossover to the quantum disordered, z = 1, regime. Since in this regime the magnitude of the gap is inversely proportional to the correlation length, which is smaller in YBa<sub>2</sub>Cu<sub>3</sub>O<sub>6.63</sub> and YBa<sub>2</sub>Cu<sub>4</sub>O<sub>8</sub> than in  $La_{1.85}Sr_{0.15}CuO_4$ , the onset tem perature of the quantum disordered (spin gap) regime is larger and the crossover to it is more pronounced in the former two materials. Thus, unlike the scenario proposed by M illis and M onien [17], we argue that for all three materials the physical origin of the spin gap is the same. 5. Y B a<sub>2</sub>C u<sub>3</sub>O 7

For nearly stoichiom etric YBa<sub>2</sub>Cu<sub>3</sub>O<sub>6.9</sub>,  $T_1T=T_{2G}$  [1] increases as the temperature increases, while  $T_1T=T_{2G}^2$  is nearly constant (Fig.3), in agreement with the scaling prediction for the overdam ped, z = 2, regime [14]. The departure from the Korringa law  $1=T_1$  T and large copper-to-oxygen ratio of the relaxation rates shows that the antiferrom agnetic enhancement is still quite substantial. In the overdam ped regime, the spin wave branch is either destroyed, or due to the small correlation length has appreciable spectral weight only for energies much larger than the maximal temperature at which this compound is chemically stable. Therefore, for experimentally accessible temperatures no departure from the the overdam ped regime is observed.

## 6. Conclusion

We have shown that the nuclear relaxation data in a broad range of doping levels, which includes both m etallic and insulating m aterials, possesses universal features characteristic of the quantum critical regime of a clean antiferrom agnetic insulator with the dynam ical exponent z = 1. This universality suggests that well beyond the m etal-insulator transition, the spin excitation spectrum of the insulator is not yet destroyed by the electron-hole back-ground, in which case one expects a two-com ponent dynam ics for a broad range of doping levels. W hile a two-com ponent dynam ics m ay arise in a one-com ponent as well as a two-com ponent m icroscopic m cdel, we call attention to an explicit exam ple which leads to this kind of dynam ics directly, namely, a m odel of spins and ferm ions with both spin-spin (J) and weak spin-ferm ion (F) exchange interaction [21]. The robustness of the spin waves m ay be related to either their weak coupling to quasiparticles, or to quasiparticle Ferm i surfaces which are not spanned by the antiferrom agnetic ordering vector Q.

On the basis of the above analysis, we suggest the uni ed magnetic phase diagram for the cuprate superconductors shown in Fig.1; the proposed boundary between the QC and QD regimes is determined from the nuclear relaxation data shown on Fig.2. We propose

8

that as the hole doping increases, the transition from the insulating to the overdoped regin e occurs in two stages. First, the system becomes metallic; the damping of spin waves increases somewhat compared to its value in the insulator, but since the spin waves are not destroyed by the electron-hole background, the dynam ical exponent is z = 1 and the quantum critical regim e persists over a wide range of temperatures and doping levels. Then, at substantially higher doping, the dynam ical exponent crosses over to z = 2. We further argue that the spin gap phenom enon observed in the underdoped materials rejects the same e physics as the form ation of the gap for spin excitations in the the quantum disordered, z = 1, phase of an insulator. This scenario suggests that in compounds where the spin gap is observed, the temperature dependent bulk susceptibility should exhibit a downtum near the crossover from the QC to QD regime, while  $T_1T=T_{2G}$  should be temperature independent at higher temperatures. We show, in a subsequent communication [22], that our scenario leads in a natural way to a uni ed description of the results of nuclear relaxation, magnetic susceptibility, and neutron scattering experiments.

### A cknow ledgem ents

W e are grateful to M. Takigawa, T. Im ai, and C.P. Slichter for communicating their experimental data to us in advance of publication. W e would like to thank V.Barzykin, G.Blumberg, A.V. Chubukov, S.L. Cooper, E.Dagotto, D.Frenkel, L.P.Gor'kov, M.V. Klein, A.J.M illis, and D. Thelen for valuable discussions, and T. Im ai and C.P. Slichter for numerous stimulating conversations on nuclear resonance phenomena. This work has been supported by the NSF G rant DMR 89-20538 through the Materials Research Laboratory.
