#### Abstract

E ects of ferm ionic zero modes (bound states in a vortex core) on the rotational dynam ics of vortices $w$ ith spontaneously broken axisym $m$ etry are considered. The results are com pared $w$ ith the $H$ elsinkiNM R experim ents where the vortex cores were driven to a fast rotation and torsional oscillations by an NM R r.f. eld. W e predict a resonance NM R absorption on localized states at the extemal frequency com parable w ith the interleveldistance which is sim ilar to the cyclotron Landau dam ping. The resonances can resolve the localized levels in vortex cores. For a pure rotation of the core, the e ect depends on the relative signs of the vortex winding and of the core rotation; thus it is sensitive to the direction of rotation of the container. The sim ilarity $w$ ith ferm ion ic zero $m$ odes on fundam ental strings, which sim ulate the therm odynam ics of black holes, is discussed.

## I. IN TRODUCTION

Low-frequency dynam ics of vortioes in Ferm i superuids and superconductors is determ ined by low -energy excitations. If the energy spectrum of ferm ionic quasiparticles in the bulk super uid/superconducting system has a nite gap, the relevant low-energy quasiparticles occur only in vortex cores. The spectrum of ferm ions bound to the vortex core has an anom alousbranch, which crosses zero as a function of the angular $m$ om entum. It was rst found by C aroli, de Gennes and $M$ atricon [1] [1] for axisym $m$ etric vortioes in $s-w$ ave superconductors. E ects of these quasiparticles on vortex dynam ics were considered in a num ber of papers (see, for exam ple, $R$ efs.
[ chiral anom aly in quantum eld theory ${ }^{[ }[4]$. New phenom ena appear if pairing occurs into a state $w$ ith a different order-param eter sym $m$ etry. For exam ple, a new dynam ics has been recently predicted for vortioes in $d-$ w ave superconductors: D ue to the localized excitations which are concentrated near the gap nodes a nite dissipation exists even in the lim it of a very long relaxation tim $e$. $T$ his happens due to the Landau dam ping on zerosound collective $m$ odes in the 1D Ferm i-liquid of the localized states. [] The particular im portance of bound states near the gap nodes in d-w ave superconductors has been already dem onstrated for the density of states $\left[{ }_{[6}^{6}\right]$ : a single-vortex density of states w as predicted to exhibit a singular $1=E$ energy dependence resulting in a tem perature independent vortex contribution to the speci c heat.

In the present paper, we consider e ects of bound states on dynam ics of nonaxisym $m$ etric vortices which $m$ ay exist in super uids $w$ ith unconventionalpairing. In particular, we consider vortices whose nonaxysym $m$ etric
cores can rotate $w$ ith respect to the heat bath. This case is distinct from dynam ics of (generally nonaxisym $m$ etric) vortioes in d-w ave superconductors where how ever the orientation of vortex cores is xed by the crystal lattice, and only a translationalm otion is possible. Such nonaxisym $m$ etric vortices exist, for exam ple, in super uid ${ }^{3} \mathrm{He}$ eB where the super uid environm ent and the heat bath are hom ogeneous and isotropic, while the vortex core exhibits spontaneous anisotropy in the crossectional plane. This spontaneous breaking of the continuous $U$ (1) symm etry (axial sym metry) of a single vortex core occurs below the vortex-core transition [ to the breaking of the electrom agnetic $U$ (1) sym $m$ etry in the core of a cosm ic string (the so-called superconducting string). [ $\left.\underline{\sigma}_{1}^{1}\right]$

In ${ }^{3} \mathrm{H}$ e-B vortex experim ents, the nonaxisym $m$ etric vortex cores were driven to fast rotational oscillations plus rotation $w$ ith a constant velocity under an applied r.f. eld. ${ }^{-1}[1]$ In In the present paper, we resolve the existing controversy conceming estim ations of the e ect ofthe core anisotropy on vortex dynam ics [ 1 [1] $]$. We nd that the $m$ ain e ects come from the ferm ion ic zero $m$ odes in the nonaxisym $m$ etric vortex core. In particular, they lead to resonances which should be observed at lower tem peratures when the extemal frequency of the core oscillations! is a multiple of the distance betw een the energy quantum levels in the core. Such resonances were rst predicted in $R$ ef. $\left[11_{1}^{1}\right]$ for the translationalm otion of the axisym $m$ etric vortices in superconductors, but they were never observed due to a di culty ofexciting translational vortex oscillations w ith the required frequency.

W e also consider the case when the core rotates around its axisw ith a constant angularvelocity. The frictional torque has an asymmetry w ith respect to the relative signs of the vortex winding num ber and the sense of core
rotation; it thus can be detected by changing the direction of one of the rotations. W hen becom es equal to the interlevel spacing gapless ferm ions appear; this has a close sim ilarity to a d-w ave superconductor.
$F$ inally, we discuss our results in connection w th the sim ilarity betw een the ferm ionic zero $m$ odes in cores of vortices in condensed $m$ atter and ferm ionic zero $m$ odes in cores of topologicalob jects in cosm ology (cosm ic strings, walls, m onopoles, etc.). This sim ilarity allow stom odel the process of electrow eak baryogenesis in the core of a cosm ic string using the super uid ${ }^{3} \mathrm{HeB}$. $\left[\overline{4}_{1}^{1}\right] \mathrm{W}$ e consider here another aspect of vortex dynam ics related to ferm ionic zero m odes: nam ely, the possibility to sim ulate the event horizon and $H$ aw king radiation by a rotating vortex core. In this connection, the ferm ionic zero $m$ odes in a vortex core act exactly as zero $m$ odes in fundam ental strings in string description ofblack holes.

## II. H P D D R IVEN COREOSCILLATIONS

In Ref. $\left[10^{-1}\right]$ the asymmetric cores of vortices were coherently driven into a rotational and oscillatory motion using a special and unique dynam ical state $w$ ith the coherently precessing $m$ agnetization, know $n$ as the H om ogeneously Precessing D om ain (HPD). This phasecoherent precession is a $m$ agnetic counterpart of a super-
uid coherent state and has the sim ilaro -diagonallongrange order, thus representing them agnetic super uidity. The principles of HPD can be found in the review [12 $\left.{ }_{2}^{1}\right]$. The coherent precession has been used to study di erent properties of super uid ${ }^{3} \mathrm{HeB}$. In particular, (i) vortioes $w$ ith an asym $m$ etric core [1] d] (analogs of the $W$ itten superconducting strings $[\overline{9}])$ and (ii) vortices form ed at term ination lines of solitons [13] (analog of strings as term inations of alls in cosm ology [14]), have been detected using HPD.

In the HPD, the m agnetization precesses $w$ th the r.f. frequency $!_{\mathrm{RF}}$. The core is driven into m otion due to the dipole torque according to the follow ing equation [10 ${ }_{1}^{-1}$ ]:

$$
\begin{equation*}
f_{f r}=B \sin 2\left(!_{R F} t\right)+G \sin 2: \tag{1}
\end{equation*}
$$

Here is the angle of the core an isotropy directord in the plane transverse to the vortex axis, $d=\hat{x} \cos +\hat{y} \sin$ (see Fig.a); the dipole torque, $T_{D}$, and the friction param eter, $f_{\text {fr }}$, are nonzero if the core is anisotropic. The restoring torque $\mathrm{T}_{\mathrm{R}}$ appears in a tilted magnetic eld which determ ines a preferred orientation for the vortex anisotropy director. U nder the condition of the experim ent, the friction torque $!_{R F} f_{f r}$ is large com pared w ith the driving dipole torque $\mathrm{T}_{\mathrm{D}}$. A s a result, the core perform s sm all and fast oscillations superim posed on a slower drift ( $(\mathrm{t})$ :

$$
\begin{equation*}
(t)=!\cos 2\left(!_{\mathrm{RF}} t\right)+: \tag{2}
\end{equation*}
$$

Thee ective drift velocity is nonzero for a com paratively sm all restoring torque $T_{R}<T_{D}^{2}=2!_{R F} f_{\text {fr }}$. From Eq. [in 1 follows that for zero restoring torque, the drift angular velocity is $\quad-=T_{D}^{2}=2 f_{f r}^{2}!_{R F}$, i.e., it is $m$ uch sm aller than the HPD precession frequency. The am plitude of core oscillations is $!=T_{D}=2 f_{f r}!_{R F}$,

In principle, the core can perform a pure rotational $m$ otion, too. This happens either for $s m$ all friction $2!_{R F} f_{f r}<T_{D}$ when $=!_{R F}$, or if the core is tw isted by the NMR r.f. eld: after the the extemal drive is sw itched o the core starts to untw ist through a free m otion. [1]d W e consider here both pure rotation and pure oscillations.

The dom inating contribution to the friction com es from kinetics of ferm ions in the rotating core which is thus the prim ary ob ject of our investigation. We nd that Eq. $\left(\underline{I}_{1}^{\prime}\right)$ has a very lim ited applicability since it does not contain the proper frequency dependence. W e derive the correct vortex dynam ics which also includes the resonance absorption, i.e., the Landau dam ping on the \zero-sound-like" m odes in the system of localized ferm ions in the vortex core.

## III. EFFECT OF FERM IONIC ZERO MODESON COREDYNAMICS.

Q uasiparticles bound to the vortex. The low-energy spectrum of C aroli-de-G ennes M atricon quasiparticles around a vortex contains an anom alous branch of ferm ionic zero modes. Excitations on this branch are characterized by two canonically conjugated variables, the angle of the transverse linear $m$ om entum $p$ ? of the quasiparticle, say with respect to the core anisotropy direction $d$ (see Fig.a), and the angular mom entum $Q$. For superconductors w th the coherence length much larger than the inverse Ferm im om entum, $\mathrm{p}_{\mathrm{F}} \quad 1$, the electron w avelength is short com pared w th the core size, and the quasiclassical approxim ation is relevant. In the quasiclassicalapproxim ation, the variables and $Q$ com $m$ ute and the spectrum has the form

$$
\begin{equation*}
\left.E(Q ;)=!_{0}() Q \quad Q_{0}()\right]: \tag{3}
\end{equation*}
$$

The quasiclassical angular $m$ om entum $Q$ is a continuous variable; thus the anom alous branch crosses zero as a function of $Q$ at $Q=Q_{0}($ ). In particular, one has $Q_{0}=0$ when the vortex-core structure is com pletely sym m etric. $\mathrm{Q}_{0}$ becom es nite if parity is violated. This was found by Schopohl [1] ${ }_{1}^{-1}$-1 $]$ for a nonaxisym $m$ etric vortex in ${ }^{3} \mathrm{HeB}$; tw o anom alous branches, which cross zero at tw o antisym $m$ etric values, $Q=Q_{0}(1)$, are schem atically shown on $F$ ig.b. The $m$ agnitude of $Q_{0}()$ in continuous vortices in ${ }^{3} \mathrm{He}-\mathrm{A}$ is determ ined by the core size of the
 core radius is of order of coherence length , this esti$m$ ation gives a large value of $Q_{0} \quad P \quad$, in accordance

F IG .1. (a) Tra jectory of the quasiparticle near the asym $m$ etric vortex core. A ngle show sthe orientation of the core anisotropy vectord; angle show sthe direction of the transverse linearm om entum $p$ ? of the quasiparticle $w$ ith respect to d ; and b is the im pact param eter. (b) Q uantization of the fast $m$ otion along the tra jectory gives tw o branches of low energy spectrum $\mathrm{E}_{1 ; 2}(\mathrm{~b} ;$ ) in term s of the rest (slow) variables, b and
. Instead of the im pact param eter it is better to use the continuous angularm om entum $Q=b \dot{p}$ ? j. A safunction of $Q$ the spectrum $\mathrm{E}_{1 ; 2}(\mathrm{Q} ;)$ crosses zero at tw o antisym $m$ etric values of $Q$, which depend on $: Q=Q_{0}()$. At the next stage the true quantum $m$ echanical levels are obtained by quantization of slow $m$ otion using the B ohr-Som $m$ erffld rule for the canonically conjugated variables $Q$ and $: d Q(; E)=2 n h$. T his gives the equidistant levels $\mathrm{E}=\mathrm{nE} \mathrm{O}_{\mathrm{o}}$.
w th the unpublished calculations by Schopohl for the nonaxisym m etric vortex w ith broken parity, the so called v -vortex. [1] ${ }^{-1}{ }^{-1}$ ]
$K$ inetic equation for the distribution function $f(t ; q)$ of ferm ions on the anom alous branch for a system characterized by canonically conjugated variables has a conventional form [18]:

$$
\begin{equation*}
\frac{@ f}{@ t}+\frac{@ f}{@} \frac{@ E}{@ Q} \quad \frac{@ E}{@} \frac{@ f}{@ Q}=\frac{f}{}= \tag{4}
\end{equation*}
$$

Here $@ \mathrm{E}=@ \mathrm{Q}=\quad!_{0}\left(\mathrm{I}\right.$; $\mathrm{f}_{0}$ is the equilibrium Ferm idistribution function.

If the vortex core rotates the quasiparticle energy depends on tim e according to $E(Q ; \quad ; t)=E(Q ; \quad(t))$. A fter transform ation $\quad$ ( t ) ! one obtains the follow ing kinetic equation:

$$
\begin{equation*}
\frac{@ \mathrm{f}}{@ t}\left(!_{0}+-1 \frac{@ \mathrm{f}}{\varrho} \quad \frac{@ \mathrm{E}}{\varrho} \frac{@ \mathrm{f}}{\varrho Q}=\frac{\mathrm{f} \quad \mathrm{f}_{0}}{}:\right. \tag{5}
\end{equation*}
$$

O ne can w rite

$$
\begin{equation*}
\mathrm{f}_{1}=\mathrm{f} \quad \mathrm{f}_{0}=\left(\mathrm{df}_{0}=\mathrm{dE}\right): \tag{6}
\end{equation*}
$$

If $\quad=+\perp e^{\mathrm{i}!\mathrm{t}}=\mathrm{i}!!\mathrm{e}^{\mathrm{i}!\mathrm{t}}$ is a perturbation w th a frequency ! $=2!_{\mathrm{RF}}$, one has

$$
\begin{equation*}
i!+\frac{1}{-} \quad!_{0} \frac{\varrho}{@} \quad \frac{@ E}{@} \frac{\varrho}{\varrho Q}=-\frac{@ E}{@}: \tag{7}
\end{equation*}
$$

Friction torque on a rotating core from ferm ions on the bound states in the core is

$$
\begin{align*}
T_{f}(!)= & Z \frac{d p_{z}}{2} \frac{d d Q}{2} \frac{@ Q}{@ t} \frac{@ f_{0}}{@ E}  \tag{8}\\
& =\frac{\mathrm{dp}_{\mathrm{z}}}{2} \frac{d \mathrm{dQ}}{2} \frac{@ E}{@} \frac{d f_{0}}{d E}:
\end{align*}
$$

T he eigen-states or zero-sound-like collective $m$ odes in the Ferm i-liquid of localized states are obtained as solutions of the hom ogeneous equation, the Eq. $\left(\bar{\eta}_{1}\right)$ w thout the driving tem on the right hand side:

$$
\begin{align*}
& 0(; Q ;!)=\mathbb{Z}(; Q)] E^{F(;!)} ;  \tag{9}\\
& F(;!)=\int_{0} d^{0} g\left({ }^{0} ;!\right) ; g(;!)=\frac{i!+1=}{!o()} \tag{10}
\end{align*}
$$

where ( $E$ ) is an arbitrary function of $E$. The eigenvalues are obtained from the requirem ent of periodicity

$$
\begin{align*}
& (; Q)=(+2 ; Q): \\
& \quad Z_{2} \quad \mathrm{~d} g(;!)=2 \mathrm{ni} ;
\end{align*}
$$

where n is an integer. In the collisionless regim e , this gives eigen frequencies of the collective $m$ odes:

$$
\begin{equation*}
!=n E_{0} ; \frac{1}{E_{0}}=Z_{0}^{Z_{2}} \frac{d}{2} \frac{1}{!_{0}()} \frac{1}{!_{0}} ; \tag{12}
\end{equation*}
$$

$H$ ere $E_{0}\left(p_{z}\right)$ is an exact $m$ inigap as distinct from the
 $T$ he Landau dam ping on these discrete frequencies occurs even in the collisionless regim e. It is com pletely analogous to the Landau cyclotron dam ping. Let us consider this in $m$ ore detail.

G eneral solution of the Eq. $\left(\bar{T}_{1}\right)$ can be found from the follow ing consideration. Since both the energy $\mathrm{E}(; Q)=$
$!_{0}\left(Q \quad Q_{0}\right)$ and the rh s. of Eq. $\left(\bar{T}_{1}\right)$ are binom ials of $Q$, a general solution can also be represented as a binom ial in $Q$, and thus as a binom ial in $E:$

$$
\begin{equation*}
(; Q ;!)=[a(;!) E(; Q)+b(;!)] e^{F(;!)}: \tag{13}
\end{equation*}
$$

$T$ he functions $a$ and $b$ satisfy the equations

$$
\begin{equation*}
\frac{@ \mathrm{a}}{@}=\frac{\perp}{!_{0}^{2}} \frac{@!_{0}}{@} e^{\mathrm{F}(;!)} ; \frac{@ \mathrm{~b}}{@}=+\frac{@ Q_{0}}{@} e^{F(;!)}: \tag{14}
\end{equation*}
$$

At sm all $T$ the linear-in E term in Eq. (13) is sm all and thus only the equation for $b(;!)$ is im portant. The solution for b consistent $w$ ith the periodicity of gives for E ! 0

$$
\begin{align*}
(;!)= & +e^{F(;!)} \mathrm{Z}_{0} \mathrm{~d} \frac{0 Q_{0}}{@ 0} e^{F\left({ }^{\circ} ;!\right)} \\
& +\frac{1}{e^{F(!)}} \mathrm{Z}_{2} \mathrm{~d} \frac{\varrho Q_{0}}{@} e^{F(;!)} ;
\end{align*}
$$

where F (!) F (2; !).
Landau cyclotron dam ping. In the collisionless lim it and close to a pole at ! $=\mathrm{nE}_{0}$ one has

$$
\begin{array}{r}
\left(;!\quad n E_{0}\right)=\frac{-1}{2 i} \frac{E_{0}}{n E_{0}+i=} \\
\quad E_{2}\left(; n E_{0}\right)_{2} d \frac{@ Q_{0}}{@} e^{F\left(; n E_{0}\right)}: \tag{16}
\end{array}
$$

The torque on the core is

$$
\begin{equation*}
\mathrm{T}_{\mathrm{f}}(!)=\quad \dot{Z}^{\mathrm{Z}} \frac{\mathrm{dp}_{z}}{2} G\left(!; p_{z}\right) \quad \text { 委 }(!) \tag{17}
\end{equation*}
$$

C lose to the resonance one has the response

$$
\begin{array}{r}
G\left(!; p_{z}\right)=\frac{i E_{0}}{!} \frac{n E_{0}+i=}{@} e^{\mathrm{C}\left(; E_{0}\right)} \frac{@ Q_{0}}{@} e^{F\left(; n E_{0}\right)}:
\end{array}
$$

Let us consider the resonance absorption in the sim ple m odel in which ! 0 does not depend on while the core anisotropy is represented only by the function $Q_{0}$ (_). $T$ his $m$ odel is close to what was found by Schopohl [15 [1] . In the sim ple model of constant ! 0 , one has

$$
G\left(!; p_{z}\right)=\frac{i E_{0} n^{2} Q_{0 n} J^{2}}{!} \mathrm{nE}_{0}+\mathrm{i}=Q_{0 n}=\frac{\mathrm{Z}}{2} Q_{0}() e^{\mathrm{in}} ;
$$

where $Q_{0 n}$ is the $n$-th harm onic of the $Q_{0}()$.
$T$ he $p_{z}$ dispersion of the exact $m$ inigap $E_{0}\left(p_{z}\right)$ results in form ation of an absonption band [11] . If the frequency ! falls $w$ th in the band, the poles in $G\left(!; p_{z}\right)$ give rise to the Landau dam ping even in the com pletely collisionless lim it: the friction coe cient is
$w$ here $p_{z n}$ is the $m$ om entum for which the resonance condition, $\mathrm{nE}_{0}\left(\mathrm{p}_{\mathrm{zn}}\right)=!$, takes place.

NM R absonption: Collisionless regim e. Eq. ( $\left.\overline{11}_{11}^{1}\right)$ is m odi ed due to the frequency dispersion of the response function:

$$
\begin{equation*}
\mathrm{f}_{\mathrm{fr}}(!)_{\perp}=\mathrm{T}_{\mathrm{D}} ; \tag{20}
\end{equation*}
$$

which gives the NM R resonant absorption

$$
\begin{equation*}
P=\frac{1}{2} R e f_{f r}(!) j, ~ J=\frac{1}{2} T_{D}^{2} \operatorname{Ref}_{f r}^{1}(!): \tag{21}
\end{equation*}
$$

In the collisionless regim e, Eq. (1] ${ }^{(1-1)}$ ) can be used. The resonant absorption starts $w$ ith a sharp $m$ in im um in the background absorption. Indeed, if! is at the edge of the band $\mathrm{nE}_{0}\left(\mathrm{p}_{\mathrm{z}}\right)$ where $\mathrm{dE}_{0}=\mathrm{dp}_{\mathrm{z}}=0$ the absonption proportional to $\mathbb{R e} f_{\text {fr }}(!)=\operatorname{fif}_{\text {fr }}(!) \jmath^{3}$ decreases sharply due to an in nitely large realpart of ffr (!). It goes exactly to zero in the ideal collisionless lim it. O bservation of these \van H ove" zeroes would resolve the $m$ inigap in NM R experi$m$ ents.

NM R absorption: H ydrodynam ic lim it. In the hydrodynam ic lim it, ! 0 . 1 , we have F (!) 1 , and the
rst term in Eq. expression

$$
\begin{equation*}
=-\frac{Q_{0}}{@} \frac{!_{0}}{i!+1=} \tag{22}
\end{equation*}
$$

The friction param eterw hich enters the NM R absonption in Eq. (21 $\underline{1}_{1}$ ) becom es
where h: : : $i_{F}$ is the average over the Ferm i surface.
The experim ent of $R$ ef. $\left.[1]{ }^{-1}\right]$ has been carried out in the tem perature range $0: 48 \mathrm{~T}_{\mathrm{c}}<\mathrm{T}<0: 6 \mathrm{~T}_{\mathrm{c}}$ while, according to R ef. $[\overline{4}]$, the hydrodynam ic regim e $!_{0}<1$ occurs only above $T \quad 0: 6 \mathrm{~T}_{\mathrm{C}}$. Let us com pare, how ever, the theory and experim ent at $T=0: 6 \mathrm{~T}_{\mathrm{C}}$. The experim ental value of the friction param eter in Eq. ([İ1), $\mathrm{f}_{\text {fr }}^{1} \quad 5 \quad 10^{18}$ erg
 derivative $@ Q_{0}=@$ is not inconsistent $w$ ith the Schopohl result: $Q_{0} \quad$ Pr $\quad$ However, since $T$ is not $s m$ all in the experim ent, the $T^{2}$ term which results from the om itted energy-dependent term $s$ in $E q$. (1-5) can be im portant and can give a com parable contribution to $f_{f r}$. The tem perature is to be decreased to resolve the value of $Q_{0}$.

## IV. UN IFORM COREROTATION.

If the vortex core rotates $w$ ith a constant angular velocity the asym ptotic solution is tim e independent and obeys the equation

$$
\begin{equation*}
\underline{1} \quad\left(!_{0}+\right) \frac{\varrho}{\varrho} \quad \frac{\varrho E}{@} \frac{\varrho}{\varrho Q}=\frac{\varrho E}{@}: \tag{24}
\end{equation*}
$$

$T$ he case of a slow rotation is equivalent to Eq . (22_) with ! = 0 and _- $=$. In the hydrodynam ic lim it, we thus have Eq. (23).
$T$ he case ofa fast rotation !o can be considered as a linear responce only in the lim it of a sm all anisotropy, $@!0_{0}=@ \quad!0$ and $@_{0}=@ \quad Q_{0} \cdot U$ sing the perturbation theory in the anisotropy param eters, we can solve the kinetic equations for both high and sm all relaxation rate. U sing the ansatz of Eq. (1]), we nd the periodic solution

$$
\begin{equation*}
=d_{0}^{Z_{2}} \frac{\left({ }^{0}\right)}{e}+\frac{(0)}{1} \mathrm{e} b\left({ }^{0}\right) e^{\left({ }^{0}\right)} \tag{25}
\end{equation*}
$$

where

$$
\begin{align*}
\mathrm{b}(~) & =\frac{!_{0}}{!_{0}+} \frac{Q_{0}}{@} ;  \tag{26}\\
() & =\frac{\left(!_{0}+\right)}{} ; \quad(2): \tag{27}
\end{align*}
$$

For T ! 0 when $\mathrm{df}_{0}=\mathrm{dE}=(\mathrm{Q} \quad \mathrm{Q})=!0$ and $d E=d=!{ }_{0} d Q_{0}=d$, one obtains the response function

$$
\begin{array}{r}
G(0)=\frac{!_{0}}{!_{0}+} \mathrm{Z}_{2} \frac{d d^{0}}{2} \\
\frac{\left(0^{0}\right)}{e}+\frac{(0,}{1} \frac{Q_{0}}{@} \frac{Q_{0}}{@} e^{\left({ }^{0}\right)}: \tag{28}
\end{array}
$$

Resonance. Eq. (20-q) essentially depends on the sense of the rotation of the vessel, which determ ines the relative signs of $!0$ and . The most interesting situation occurs when $!0$ and have opposite signs. In this case the resonance absonption should occur when is close to ! o. In the hydrodynam ic regim e, j! $0+j 1=$, the frictionaltorque coincides with Eq. (23). In the intermediate regím e, j! $0+j \quad 1=\quad j!0<!>j$ one obtains

$$
\begin{equation*}
\mathrm{f}_{\mathrm{fr}}=\frac{\mathrm{p}_{\mathrm{F}}}{*} \frac{!_{0}}{\left(!_{0}+\right)^{2}}{\frac{\mathrm{Q}_{0}^{2}}{\mathrm{hQ}_{0} \mathrm{i}^{2}}}_{\mathrm{F}}^{\text {+ }} \tag{29}
\end{equation*}
$$

U sing Eq. $(2 \overline{2} \overline{9})$ and Eq. $(2 \overline{3})$, one can approxim ate the resonance absonption by

$$
\begin{equation*}
\mathrm{f}_{\text {fr }}=\mathrm{p}_{\mathrm{F}}^{\mathrm{D}}!_{0}\left(!_{0}+\right)^{\mathrm{h}} \mathrm{Q}_{0}^{2} \quad \mathrm{~h}_{0} \mathrm{i}^{2}{ }_{\mathrm{F}}^{\mathrm{iE}} ; \tag{30}
\end{equation*}
$$

If, for the proper sense of rotation, the function $!0\left(p_{z}\right)+\quad$ crosses zero at some $p_{z 0}$, the friction rem ains nite even in the lim it $1=b$ (how ever, has to be sm all com pared to the inverse dispersion):

$$
\begin{align*}
& f_{f r}=\frac{Z}{2} d_{p}!_{0}\left(!_{0}+\right)^{h} Q_{0}^{2} \quad h Q_{0} i^{i} \\
& =\frac{!_{0}}{\dot{j}!!_{0}=\mathrm{dp}_{z} \dot{p}_{z 0}} \quad \mathrm{~h} \mathrm{Q}_{0}^{2} \quad \mathrm{~h} \mathrm{Q}_{0} \mathrm{i}^{\mathrm{i}^{i}}: \tag{31}
\end{align*}
$$

In the sim ple-core $m$ odelw here $!_{0}$ is independent of and $Q_{0}$ has only one harm onic,

$$
\begin{equation*}
Q_{0}()=g \cos ; \tag{32}
\end{equation*}
$$

the solution is

$$
\begin{equation*}
=A \sin +B \cos ; A=\frac{!_{0} g}{1+\left(!_{0}+\right)^{2}}: \tag{33}
\end{equation*}
$$

$T$ he factor $B$ is not im portant since it does not contribute to the friction torque. T he friction torque has a resonance behavior

$$
\begin{equation*}
G\left(p_{z}\right)=\frac{g^{2}}{2} \frac{!_{0}}{1+\left(!_{0}+\right)^{2}}: \tag{34}
\end{equation*}
$$

 and Eq. (23) for the hydrodynam ic regim e.

## V.D ISCUSSIO N

$T$ he interesting problem s to be discussed in the future are related to the resonance behavior, which occurs w hen the edge of the $m$ inigap band $!0()$ as a function of crosses the angular velocity of the unifrom rotation. If the bottom of the band is chosen at $=0$ (and also at
$=$ due to symmetry of the core) one has near the
bottom

$$
!_{0}(1)+\quad!_{0}(0)++\frac{1}{2} \quad 2 ; \quad=d^{2}!_{0}(0)=d^{2}:
$$

At the $m$ om ent when touches the bottom $!_{0}(0)$, the shifted $m$ inigap ! o ( ) + has nodes of a second order. The same situation occurs for non-rotating vortioes in the d-w ave superconductors. T he higher-order gap nodes have seriou s consequences for the vortex therm odynam ics [ ${ }_{2}^{-1}$ occurs even in the superclean lim it.

Let us start with a sm all positive ! $0(0)+\quad$ and then continue it analytically to a negative value. W e are interested in the B ose-factor in Eq. (25) in the collisionless lim it $=1$ with a nite frequency !. Substituting $1=$ $w$ ith $i!$, we nd for $0<b(0)+\quad!_{0}(0)$

$$
\begin{align*}
& 2 i!\quad=2 \frac{d}{Z} \quad \frac{!_{0}(0)+\frac{1}{2}^{2}}{}  \tag{35}\\
& p \frac{2 \text { i! }^{\mathrm{p}} \overline{2}}{\left(!!_{0}(0)+\quad\right)} \text { : }
\end{align*}
$$

Here we took into account that the integral is concentrated in the vicinity of $=0$ and also in the vicinity of $=$. The analytical continuation of Eq. (3-5﹎﹎) to a sm all negative ! o (0) + gives a real quantity

$$
\begin{equation*}
\frac{2!^{\mathrm{P}} \overline{2}}{j+!_{0}(0) j}=4 \frac{!}{\left.j!_{0}=@ \dot{j}_{0( }\right)=}: \tag{36}
\end{equation*}
$$

The B ose-factor in Eq. (2-5) thus corresponds to an equilibrium distribution w ith an e ective tem perature determ ined by the derivative of the m inigap $!_{0}(\mathrm{)}$ at the point where $!_{0}(\mathrm{l}=$ :

$$
\begin{equation*}
\frac{1}{\mathrm{e}^{!=\mathrm{T}_{\text {eff }}}} ; \mathrm{T}_{\mathrm{e}}=\frac{1}{4} \quad \frac{@!_{0}}{@} \quad!_{0()=}: \tag{37}
\end{equation*}
$$

This has a close relation w ith the event horizon problem [ $\left.20^{\prime} 1\right]$. Recently there was a profound progress in
 hole therm odynam ics using the fiundam ental strings (see recent review paper by H orow itz [2]ind). The statistical origin of the black hole therm odynam ics is related to ferm ion and boson zero $m$ odes of strings. Excitations having the lowest energy are con ned to a circle and are chiral: they are, say, right-m oving along the circle. Ferm ions localized in the core of a quantized vortex in a superconductor or in a Ferm i-super uid of the type of super uid ${ }^{3} \mathrm{H}$ e have sim ilar properties $\left[\underline{I n}_{1}^{-1}\right]$. The m odel of a vortex core where ferm ions live on a closed line around the vortex axis in real space was discussed in Ref. [2]4]. $T$ he low est energy branch (the ferm ionic zero mode in the vortex) represents $1+1 \mathrm{~m}$ assless ferm ions, which are left-m oving (right-m oving) around the axis of the vortex, if the vortex has a positive (negative) winding num ber. The axial anom aly caused by the ferm ion zero $m$ odes during motion of vortiges (strings) in ${ }^{3} \mathrm{He}$ and superconductors [2]-[] has experim entally observable consequences for the vortex dynam ics. $\left.\overline{\|_{1}^{\prime}}\right]$

If the canonically conjugated variables on the circle, i.e., the angle and the angular $m$ om entum $Q$, are represented as the coordinate $\mathrm{x}=$ and the m om entum $p=Q$, the spectnum of ferm ionic zero $m$ odes of the type of Eq. ( $\bar{\beta}_{1}$ ) describes a m assless relativistic particle leftm oving along the circle,

$$
\begin{equation*}
E(p ; x)=C(x)(p \quad A(x)): \tag{38}
\end{equation*}
$$

H ere $c(x)=!_{0}(x)$ plays the part of the speed of light, and $Q_{0}()=A(x)$ is the vectorpotential. $T$ his spectrum is universal, though the details, i.e., the fiunctions $C(x)=$ $!_{0}()$ and $A(x)=Q_{0}()$, depend on a particular vortex structure in a particular super uid/superconductor.

The gas of these $1+1 \mathrm{~m}$ assless chiral ferm ions has the required statistical properties. For exam ple, if we consider the axisym $m$ etric core, the quasiparticle enrgy spectrum in term $s$ of the angular $m$ om entum quantum number $Q$ is $E=!_{0} Q$. For such spectrum the num ber of quantum states $w$ th the xed total angular $m$ om entum $Q$ is [2]

$$
\begin{equation*}
e^{s} ; s=2^{p} \overline{Q=12}: \tag{39}
\end{equation*}
$$

T he sam e happens also for the nonaxisym $m$ etric vortex, since its energy spectrum is also linear in quantum num ber, $\mathrm{E}=\mathrm{nE} 0$ according to $\mathrm{Eq} \cdot\left(\underline{1} \mathbf{1}_{1}\right)$. This m eans that
if the vortex has the nonzero $m$ om entum $Q$ (this happens for exam ple if two identical vortioes rotate about their center of $m$ ass or if the nonaxisym $m$ etric core rotates) the ferm ionic entropy $S$ of the core appears to be nonzero even at $T=0$. This violation of the " N emst
 the discrete spectrum of the radiation by the rotating core, with frequencies which are integralm ultiple of $\mathrm{E}_{0}$ in Eq. (12), is sim ilar to that by the quantum black hole. [27

In the classical lim it the rotation of the nonaxisym $m$ etric vortex can lead to the levent horizon". This happens when $j$ j > ! o (0) and the \speed of light", $c(x)=!_{0}()+$, crosses zero at som e values of $x$. The analogue of the $H$ aw king tem perature is to be played by the spatial derivative of the speed of light at horizon, $\mathrm{T}_{\mathrm{H} \text { aw king }}=(1=2) j(\mathrm{dc}=\mathrm{dx})_{\mathrm{hor}} j=j\left(\mathrm{~d}!_{0}=\mathrm{d}\right)!_{0( }()=j$. $T$ his is two tim es larger than the e ective tem perature in Eq. (3 $\bar{T}_{1}$ ) probably because of tw o \black holes" in the core (close to $=0$ and close to $=$ ).

To sum m arize, we predict a resonant absorption on localized levels in an asym $m$ etric vortex core perform ing rotational oscillations which are sim ilar to the cyclotron Landau dam ping. For a pure rotation of the core around its axis $w$ ith a constant angular velocity , the frictional torque has an asymmetry with respect to the relative signs of the vortex w inding num ber and the sense of core rotation.

## ACKNOW LEDGMENTS

GEV thanks Ted Jacobson for the collaboration on the horizon problem. This work was supported by the Russian Foundation forFundam entalR esearch grant No. 96-02-16072 and by the program \StatisticalP hysics" of the M in istry of Science of R ussia. NBK also acknow ledges the support by the Sw iss N ationalFoundation cooperation grant 7SUP J048531 and by the $\mathbb{I N T A S}$ grant 960610. GEV acknow ledges the support by the European Science Foundation.
