# D ensity $m$ atrix renorm alization group for the B erezinski-K osterlitz-T hou less transition of the 19-vertex m odel 

YasushiH onda and T suyoshiH origuchi<br>D epartm ent of $C$ om puter and $M$ athem atical Sciences, $G$ raduate School of Inform ation Sciences,<br>Tohoku U niversity, Sendai 980-77, Japan

#### Abstract

We em body the density $m$ atrix renorm alization group (DM RG) m ethod for the 19-vertex $m$ odelon a square lattice in order to investigate the $B$ erezinskii$K$ osterlitz-T houless transition. E lem ents of the transfer $m$ atrix of the 19vertex $m$ odelare classi ed in term $s$ of the total value of arrow $s$ in one layer of the square lattice. By using this classi cation, we succeed to reduce enor$m$ ously the dimension of the $m$ atrix which has to be diagonalized in the DM RG method. We apply our method to the 19 -vertex model with the interaction $K=1: 0866$ and obtain $c=1: 006$ (1) for the conform al anom aly. PACS.05.90.+m, 02.70.c

## I. IN TRODUCTION

The density $m$ atrix renorm alization group (D M RG) m ethod is developed to obtain eigenvalues off am iltonian $m$ atrix for one-dim ensionalquantum system $s$ [īj. Thism ethod enables us to investigate a nite system with a large size by a num erical calculation of $m$ atrices, which can be handled w ithin recent com puter resouroes such as a $m$ em ory size and a qpu speed. R ecently the D M RG m ethod has been applied to the transfer m atrix of classical spin system $s \overline{\underline{Z}}]$. In the both cases of quantum system $s$ and classical system $s$, each spin variable has a discrete degree of freedom. Therefore we have $m$ atrices $w$ ith a nite dim ension for these nite system s . On the other hand, the dim ension of the transfer $m$ atrix becom es innite for a nite system of spins with continuous degree of freedom such as a classical XY m odel. Fortunately it is known that the XY model on a square lattice is translated into a 19-vertex $m$ odel for which the transfer $m$ atrix is described in term $s$ of realization of arrow variables [3].]. An arrow variable takes three discrete states. H ence the 19 -vertex m odel is called a three-state vertex $m$ odel. $W$ e can construct the transfer $m$ atrix with a nite dim ension for a nite system of the 19-vertex $m$ odel described by the three-state variables. The 19-vertex m odel is solved by Zam oloddhikov and Fateev [i] in the case that its Boltzm ann weights satisfy the $Y$ ang-Baxter relation. T his exact solution is generalized to the $q$-state vertex m odel.by Sogo et al. have an exact solution yet for that system. H ow ever it is believed that a critical behavior of the 19-vertex $m$ odel $w$ ithout frustration belongs to the sam e universality class as the B erezinskii-K osterlitz-T houless transition

The purpose of the present paper is to embody the DMRG m ethod for the 19-vertex m odel and to show that the dim ension of $m$ atrices, which are diagonalized in the DMRG m ethod, is reduced enorm ously by using the ice rule of the 19-vertex model a value of the conform al anom aly as $\mathrm{c}=1: 006(1)$ at $\mathrm{K}=1: 0866 \mathrm{which}$ is regarded as the BKT transition point [ ${ }_{-1}^{1}$ ]. This value is consistent w ith a value of cexpected at the BKT transition point. On the other hand, the value of $=2$ appears to be $0: 1175$ (5), which is sm aller than the expected value $\frac{1}{8}$ at the BKT transition point. This suggests that the critical value of K for the 19-vertex m odel is sm aller than 1.0866 .

In section ' ${ }_{-1}{ }_{-1}$, we brie y explain the relation betw een the classical X Y m odeland the 19vertex model. In section of transfer $m$ atrix in the DMRG method. In section $\overline{\underline{N} V i, ~ w e ~ s h o w ~ o u r ~ r e s u l t s ~ a n d ~ g i v e ~}$ discussions about the conform al anom aly and the sm allest scaling dim ension. Section $\mathfrak{N}$ for a sum $m$ ary of the present study.

## II. 19-V ERTEX M ODEL

The partition function of the 19-vertex m odel is derived from that of the XY m odel. A ssigning Boltzm ann weights to 19 vertices, the 19 -vertex m odel describes the X Y m odel on a square lattioe for each case w th frustrations or w thout frustrations. For spin variables, which take continuous values like classical XY spins or plane rotators, we have a transfer $m$ atrix $w$ ith in nite dim ension even for a nite system. Therefore the bare XY m odelcannot be handled by a num erical diagonalization of the transfer $m$ atrix. On the other hand, the 19-vertex $m$ odel is described by discrete variables which express three kinds of arrow s . H ence we can $m$ ake a transferm atrix w ith a nite dim ension and apply the DM RG procedure for a nite system. In order to dem onstrate the e ciency of our approach to the BK T transition, we apply it to the 19-vertex m odelw thout frustration for which the criticalbehavior of the usualBK T transition has to be reproduced.

Let us brie $y$ explain a relation betw een the XY model and the 19 -vertex $m$ odel on a square lattice. The partition function $Z_{X Y}$ of the $X Y \mathrm{~m}$ odel on the square lattice is de ned as follow s:

$$
\begin{equation*}
Z_{X Y}=Y_{k 2}^{Z} d_{k} \operatorname{expfK}{\underset{h i ; j i}{X} \cos \left({ }_{i} \quad j \quad A_{i j}\right) g ; ~ ; ~}_{\text {; }} \tag{1}
\end{equation*}
$$

where $i ; j$ and $k$ denote site indices ${ }_{p} i$ an angle of the $X Y$ spin at site $i, K$ an interaction param eter, respectively. The sum ${ }_{\text {hi;ji }}$ is taken over all nearest-neighbor pairs of sites. A bond param eter related to frustration between sites $i$ and $j$ is expressed by $A_{i j}$. The frustration $f$ is de ned in term s of the $A_{i j}$ as follow $s$ :

$$
\begin{equation*}
\mathrm{f} \quad \frac{1}{2}_{\mathrm{P}}^{\mathrm{X}} \mathrm{~A}_{\mathrm{ij}} ; \tag{2}
\end{equation*}
$$

where the summ ation ${ }^{P}{ }_{P}$ is taken over an elem entary plaquette. If the value of $f$ is a half odd integer, the plaquette has a frustration.

In a region of sm all param eter $K$, we expand the exponential function in the partition function for the XY m odel given in Eq. (İI). Hence let us start w ith a follow ing partition function Z:
$T$ he integrand of the partition function $Z$ has the $U$ (1) symm etry as well as that of $Z_{X Y}$. The rst term of the integrand in ins of Eq. ( (3, ) is assigned to no arrow in the 19-vertex m odel. The second term is assigned to an arrow pointing from a site $i$ to $j$ and the third term to an arrow pointing from a site $j$ to $i$. W e use a word "arrow" even for the case of no arrow in a bond. Only when the value of arrows incom ing to a site is equal to the value of arrow s outgoing from the site, a weight of the arrow con guration for the site survives after taking integrations $w$ ith respect to an angle of $X Y$ spin at the site. O therw ise the weights of arrow con gurations do not appear in the partition function. In the six-vertex $m$ odel, we have a sim ilar rule to that $m$ entioned above [ī-1]. That nule is called as the ioe rule, whose nam e com es from the property of hydrogen ions in an ioe crystal.

The 19 kinds of arrow con gurations on vertices are perm itted by an "ioe rule", which is a generalization of the ioe rule for the six-vertex model, when we include no arrow on a bond as show n in Fig'거. H ereafter we sim ply say the 19 kinds of vertioes instead of the 19 kinds of arrow con gurations on vertioes. The vertex weight $W\left(v_{i}\right)$ depends on the kind of the vertex $v_{i} 2$ f1;2; ;19g at site $i$. The value $\varphi$ fis detem ined by a con guration of four arrow $s$ as follow $s$ :

$$
\begin{equation*}
v_{i}=V_{i}(i ; i ; i ; i) ; \tag{4}
\end{equation*}
$$

where ${ }_{i}$; $_{i}$; $_{i}$ and ${ }_{i}$ denote arrow s surrounding the site i as shown in $F$ ig' an up and a right arrow by +1 , a dow $n$ and a left arrow by 1 , no arrow by 0 , respectively. For instance $v_{i}(1 ; 0 ; 0 ;+1)=1$ as shown in $F$ ig'in. ${ }_{1}$. The ioe rule is described in term $s$ of i; i; i and i as follow s:

$$
\begin{equation*}
i \quad i \quad i+i=0 \text { : } \tag{5}
\end{equation*}
$$

U sing the weights for 19 vertioes, we can describe the partition function $Z$ as follow $s$ :

$$
Z=\underbrace{X}_{\mathrm{fv}_{\mathrm{i}} \mathrm{~g} \text { i } 2} \quad \begin{align*}
& Y  \tag{6}\\
& W
\end{align*}\left(\mathrm{v}_{\mathrm{i}}\right) ;
$$

where the sum $m$ ation is taken over all perm itted con gurations of the vertex on the lattioe
III. DENSITY MATRIX RENORMALIZATION GROUP METHOD W ITH RESTRICTIONSON THE TOTALVALUE OFARROW S

Because there exists the ice rule for the 19-vertex $m$ odel, the transfer $m$ atrix, by which the partition function $Z$ is expressed, becom es a block diagonal form. This block diagonal form is obtained in term s of classi cation by the value of arrows incom ing to one layer corresponding to the transferm atrix. The layer w th length $L$ is show $n$ in $F$ ig'⿹ㅓㄱ; $L$ is the
w idth of the system . W e consider the system under periodic boundary conditions w ithout frustration in this and next sections.

From the ice rule shown in Eq. ([़-1), we have

$$
X_{i=1}^{X^{L}}(i \quad i \quad i+i)=0:
$$

Because of the follow ing relations

$$
\begin{align*}
& i=i+1 ;\left(\begin{array}{lll}
1 & i & L
\end{array}\right)  \tag{8}\\
& L+1=1 ; \tag{9}
\end{align*}
$$

Eq. (7, י1) becom es

$$
\begin{equation*}
X_{i=1}^{X^{L}} \quad i=X_{i=1}^{X^{L}}: \tag{10}
\end{equation*}
$$

H ere we note that Eq. $(\underset{-1}{\overline{9}})$ com es from the periodic boundary conditions. T he relation given by Eq. ( $\mathbf{I N}_{-1}^{-1}$ ) m eans a conservation law of the total value of arrow s . Let us de ne the total value of arrow s $N$ in one layer as follow $s$ :

$$
\begin{equation*}
\mathrm{N} \quad \mathrm{X}_{\mathrm{i}=1}^{\mathrm{L}} \mathrm{i}: \tag{11}
\end{equation*}
$$

N ow the whole transfer $m$ atrix of the 19-vertex model is classi ed by $N$ and hence has a block diagonal form . W e w ill explain this in detail in the follow ings.

By using the property ( $(\underline{1}-\overline{0})$ ), we reduce an am ount of calculation in the DM RG m ethod. W e apply the in nite system $m$ ethod of the DMRG fram ew ork to the 19-vertex model. In addition to the vertex weight $W\left(v_{i}\right)$ whose values are provided in $F$ ig'iv, we de ne a renorm alized weight $W{ }^{(r)}\left(\mathrm{v}_{\mathrm{i}}^{(r)}\right)$ where $\mathrm{v}_{\mathrm{i}}^{(r)} \mathrm{m}$ eans a renorm alized vertex and $r$ is the num ber of renorm alization. A s an initialvalue, we set $W^{(0)}\left(v_{i}^{(0)}\right)$ to be equalto $W \quad\left(v_{i}\right)$. The transfer $m$ atrix for the total value of arrow $S, N$, is com posed as

$$
\begin{align*}
& W^{(r)}\left(\mathrm{V}_{3}^{(\mathrm{r})}\left({ }_{3} \boldsymbol{i}{ }_{3} \boldsymbol{i}{ }_{4} \boldsymbol{i}{ }_{3}\right)\right) \mathrm{W}\left(\mathrm{~V}_{4}\left({ }_{4} \boldsymbol{;}{ }_{4} \boldsymbol{i}{ }_{1} \boldsymbol{i}{ }_{4}\right)\right) \text {; } \tag{12}
\end{align*}
$$

(see Fig $\frac{1,7}{4}$ ) w here the total value of arrow $s N$ is obtained by

$$
\begin{align*}
\mathrm{N} & =\mathrm{N}_{\mathrm{r}}\left({ }_{1}\right)+2+\mathrm{N}_{\mathrm{r}}\left({ }_{3}\right)+4 \\
& =\mathrm{N}_{\mathrm{r}}\left({ }_{1}\right)+2+\mathrm{N}_{\mathrm{r}}\left({ }_{3}\right)+{ }_{4}: \tag{13}
\end{align*}
$$

$W$ e denote arrow $s$ for a verticalbond at a renorm alized vertex as ${ }_{i}$ or ${ }_{i}$. The value ofarrow $s$ included in the renorm alized vertex is denoted by $N_{r}(i)$ for $i$ or $N_{r}(i)$ for $i_{i} N_{r}(i)$ and $N_{r}\left({ }_{i}\right)$ are equal to $i$ and $i$ at the initial step of the D M RG procedure.

W e denote an eigenvector of this transferm atrix by ${ }_{\mathrm{N} ; \mathrm{k}}^{(\mathrm{r})}\left({ }_{1} ;{ }_{2} ;{ }_{3} ;{ }_{4}\right)$ which corresponds
 as follow s:

N otice that the density $m$ atrix is labeled by $\mathrm{N}_{\mathrm{r}}\left({ }_{1}\right)+{ }_{2}$ not by N . This is due to the fact that ${ }_{3}$ and ${ }_{4}$ are shared by two eigenvectors constructing the density $m$ atrix as show $n$ in
 has a block diagonal form, as well as the transfer m atrix, where each block is classi ed by the total value of arrow s for the half system. T his property of the density $m$ atrix is the reason why we can reduce a dim ension of the transfer $m$ atrix by our $m$ ethod introduced in the present study

In order to construct the renorm alized vertex weight $W{ }^{(r+1)}$, we diagonalize the density $m$ atrix $\hat{N}_{r}(1)+{ }_{2 ; 1}$ and obtain its eigenvectors $\nabla_{N_{r}(1)+}{ }_{2} ;$. In the present study, we use an eigenvector of the transfer $m$ atrix for the largest eigenvalue $k=1$ as a target state. T he renorm alized vertex state is labeled by ${ }_{1}^{0}$ which $m$ eans that $\nabla_{\mathrm{N}_{r}(1)+} ;{ }_{1}^{0}$ corresponds to the
${ }_{1}^{0}$-th eigenvalue of $\hat{N}_{r}(1)+{ }_{2 ; 1} . W$ e determ ine the upper lim it lof ${ }_{1}^{0}$ as follow $s$ :

$$
1 \begin{array}{lll} 
 \tag{15}\\
& \left.\begin{array}{lll}
3^{x+2} & \left(3^{x+2}<m\right) \\
m & \left(3^{x+2}\right. & m
\end{array}\right) ;
\end{array}
$$

$w$ here $m$ is the number of states taken into account for calculation of the density $m$ atrix. For exam ple, at the initial step of the DM RG m ethod, that is, $r=0$, the value of libecom es 9 which $m$ eans the renorm alized arrow ${ }_{1}^{0}$ includes two arrow s.

The last step of the DMRG m ethod for the 19-vertex $m$ odel is a construction of the renorm alized w eight for the vertex as follow s:

$$
\begin{aligned}
& \left.\left.W^{(r+1)} \underset{X}{\left(\mathrm{~V}_{1}^{(r+1)}\right.} \underset{\mathrm{X}}{(1)} \quad{ }_{1}^{0} ; \quad 3 ;{ }_{1}^{0}\right)\right)
\end{aligned}
$$

$$
\begin{align*}
& \text { 2 1; 2 1; } 2 \tag{16}
\end{align*}
$$

$T$ his last step is ilhustrated in $F$ ig! vertex becom es

$$
\begin{equation*}
N_{r+1}\binom{0}{1}=N_{r}\left(1_{1}\right)+{ }_{2}: \tag{17}
\end{equation*}
$$

W e need also $W^{(r+1)}\left(v_{3}^{(r+1)}\left({ }_{3} ;{ }_{3}^{0} ; 4 ;{ }_{3}^{0}\right)\right)$ when we retum to the rst step of the D M RG m ethod, but we do not need to calculate it. Since in our m ethod for the 19-vertex m odel the system has a translational sym m etry, we can use $W^{(r+1)}\left(v_{1}^{(r+1)}\right)$ as $W^{(r+1)}\left(v_{3}^{(r+1)}\right)$. Then we retum to the rst step represented by Eq. (12in) in order to iterate the DM RG procedure. By iterating this procedure for the 19-vertex $m$ odel $w$ ith the restriction of the total value of arrow $s$ as $m$ entioned above, we are able to $m$ ake the system size $L$ increase system atically. $T$ he advantage of this $m$ ethod is that the dim ension of the transfer $m$ atrix decreases enorm ously by considering the conservation law of the value of arrows in this DM RG m ethod.

H ow ever we need a large enough value ofm in Eq. (1َ5디) in order to obtain a good accuracy of num erical calculations for a large system size. The results for the $m$ dependence of the present m ethod for the BKT transition are discussed in the follow ing section, along w ith the obtained other results.
IV.RESULTS FOR THE CONFORMALANOMALYAND THE SMALLEST SCALING DIMENSION

An example of the values of $N_{r}\left({ }_{i}\right)$ in the case ofm $=35 ; \mathrm{N}=0$ and $\mathrm{L}=12$ is show n in
 of the density $m$ atrix. Because the $w$ idth ofthis system, $L$, istwelve, $i$ represents ve arrow $s$. Therefore the value of $\mathrm{N}_{r}\left({ }_{\mathrm{i}}\right)$ can take one of $\mathrm{f} 5 ; 4 ; \quad ; 0 ; \quad ;+4 ;+5 \mathrm{~g}$ as listed in the rst colum $n$ of $T a b l$ lin. Since we set $m=35$, there is no eigenvalue of the density $m$ atrix w ith $\mathrm{N}_{\mathrm{r}}(\mathrm{i})=5$. These are show by crosses in Table it. W hen the value of arrow s is 4, we have only one eigenvalue, which is the 31-st eigenvalue of the density $m$ atrix. This is expressed as $N_{r}(31)=4$ in the third line of Tableit. In the sam e way as for $N_{r}\left({ }_{i}\right)=4$, we have two eigenvalues with $N_{r}(i)=3 ; N_{r}(12)=3$ and $N_{r}(26)=3$ as show $n$ in the fourth line of Table I . For other values of $\mathrm{N}_{r}\left(\mathrm{i}_{\mathrm{i}}\right)$, a distribution of i is show $n$ in the same $m$ anner explained for $N_{r}\left({ }_{i}\right)=5, N_{r}\left({ }_{i}\right)=4$ and $N_{r}\left({ }_{i}\right)=3$. $T$ he largest eigenvalue corresponds to $\mathrm{N}_{\mathrm{r}}(1)=0$. For the case of $\mathrm{m}=35$ given in Table ${ }_{\underline{I}}^{1 / 1}$, the m allest eigenvalue corresponds to $\mathrm{N}_{\mathrm{r}}(34)=+1$ and $\mathrm{N}_{\mathrm{r}}(35)=1$. These two states are degenerate. In general those two states $w$ ith $N_{r}\left({ }_{i}\right) 0$ are degenerate; we have an eigenstate $w$ ith $N_{r}\left({ }_{i}\right)$ and an eigenstate w ith $\mathrm{N}_{\mathrm{r}}\left({ }_{\mathrm{i}}\right)$ alw ays. Therefore an eigenstate distribution of the density m atrix is sym $m$ etric $w$ th respect to $N_{r}\left({ }_{i}\right)$.

The dim ension of a m atrix which has to be diagonalized in the DM RG m ethod is now enorm ously reduced by the $m$ ethod $m$ entioned in the previous section. Therefore it becom es possible to handle large values of $m$ by using our com puter resources. As an exam ple we show reduction of the dim ension of $m$ atrices of which the largest eigenvalues have to be calculated. In the case of $\mathrm{N}=0 ; \mathrm{m}=35$ and $\mathrm{L}=12$, the dimension of a matrix is $3^{12}=531 ; 441$ for a sim ple transfer $m$ atrix $m$ ethod. The dim ension of the $m$ atrix reduces
 is now 1,545 for our $m$ ethod introduced in the present study.

The largest eigenvalue of the transfer matrix belongs to the block with $N=0$ in the whole transferm atrix. H ence, the largest eigenvalue with $\mathrm{N}=0$ is used to calculate the free energy of the system. Them dependence of the value of the free energy is show $n$ in $F$ ig ${ }_{6}^{\prime} \bar{\lambda}_{1}$, . W e obtain a good convergence $w$ th the value ofm. In the case of $L=30$, calculations $w$ ith $\mathrm{m}=3^{14}=4 ; 782 ; 969$ give an exact diagonalization of the transfer $m$ atrix. Three kinds of tting functions are used to $t$ the $m$ dependence. $W$ e obtain the $s m$ allest value of standard deviation by using an exponential function. These results $m$ ean that the largest eigenvalue of the transfer $m$ atrix exponentially converges to an exact value by increasing $m$ even at the BKT transition point in ourm ethod.

The size dependence of the free energy $F$ at $K=1: 0866$, which is regarded as the BK T
 [īi] of the free energy for the system w ith periodic boundary conditions:

$$
\begin{equation*}
\mathrm{F}=\mathrm{L} \quad \mathrm{f}_{1} \quad \frac{\mathrm{C}}{6 \mathrm{~L}^{2}} \tag{18}
\end{equation*}
$$

where $f_{1}$ denotes the free energy per site in the therm odynam ic lim it. $W$ e obtain the value of the conform al anom aly as $\mathrm{c}=1: 006(1)$, which is consistent w th the value of c at the critical region.
$T$ he second largest eigenvalue of the transfer $m$ atrix belongs to a block $w$ ith $N=1$. $H$ ence the $s m$ allest scaling dim ension which is equivalent to $=2$ is estim ated by

$$
\begin{equation*}
=2=x_{0}^{(1)}=\frac{L}{2} \ln \underbrace{0^{(1)}}_{0_{0}^{0} \frac{0}{(0)}^{1}} \text {; } \tag{19}
\end{equation*}
$$

where ${ }_{k}^{(n)}$ expresses the $k$-th eigenvalue in the $N=n$ sector of the transfer $m$ atrix ${ }_{\underline{3}-1}^{1} 1$. The critical index describes an algebraical decay of a correlation function in a critical region of interaction. At the BKT transition point, the value of has to be $\frac{1}{4}$. An interaction dependence of $x_{0}^{(1)}$ is shown in $F$ ig ${ }_{1}{ }_{9}{ }_{1}$. These results shown in $F$ ig ${ }_{9}^{\prime}{ }_{9}^{9}$ are obtained by using $m=27$ for each $L$. In $F$ ig ${ }_{2}^{\prime} 9,1$ we fail to obtain the value $\frac{1}{8}$ of $x_{0}^{(1)}$ if we use $K=1: 0866$ : the value of $=2$ obviously appears to be sm aller than $1 / 8$ at $K=1: 0866$.

W e investigate an m -dependence of $\mathrm{x}_{0}^{(1)}$ at $\mathrm{K}=1: 0866$ and $\mathrm{K}=1: 0500$ up to $\mathrm{m}=120$. E xam ples of extrapolations to large values ofm by using the exponential function are show $n$ in $F$ ig ${ }_{1}^{\prime} \overline{1}-\overline{\mathrm{O}}$. W e de ne $y_{m}^{(\mathbb{N})}$ by

$$
\begin{equation*}
\mathrm{y}_{\mathrm{m}}^{(\mathbb{N})} \quad \frac{\mathrm{L}}{2} \ln {\underset{0}{(N)}, ~}_{\mathbb{N})} \tag{20}
\end{equation*}
$$

 constructed by taking account of $m$ states of the density $m$ atrix. To obtain results which are equivalent to an exact diagonalization, a large value of $m$, i.e., $m=3^{19}$, for the largest system size $L=40$, which we treat. Therefore we extrapolate the obtained results $\mathrm{Y}_{\mathrm{m}}^{(\mathbb{N})}$ to
 $\mathrm{m}=70 ; 81 ; 100$ and 120. The dotted lines are results of tting by using values from $\mathrm{m}=$ 50;70;81;100 and 120. D i erence betw een results obtained from these tw o extrapolations is shown as errors in $F$ ig 1 $x_{0}^{(1)}=0: 1255(1)$ at $K=1: 0500$ for $L=40$.
 respectively. Every points show in $F$ igs, $\overline{1} \overline{1} 1$ of $m$ as explained above. $W$ e observe that the value of $x_{0}^{(1)}$ goes to nite value for large L. The extrapolated value is about 0:1175 and obviously less than $1 / 8$ at $\mathrm{K}=1: 0866$. $T$ herefore $K=1: 0866$ is in the critical region. On the other hand, it is found that the size dependenœ of $x_{0}^{(1)}$ at $K=1: 0500$ is stronger than that at $K=1: 0866$ as shown in $F$ ig ${ }^{\prime} \overline{1} \overline{2}-\overline{1}$. In addition, the value ofx ${ }_{0}^{(1)}$ increases beyond $1 / 8$ as the system size $L$ increases. This result indicates that $K=1: 0500$ is out of the critical region.

Thus these results at $K=1: 0866$ and $K=1: 0500$ suggest that the critical value of $K$ of the 19-vertex m odel is in betw een $\mathrm{K}=1: 0500$ and $\mathrm{K}=1: 0866$. To determ ine a precise value of critical point $K_{c}$ is an interesting problem. H ow ever this problem is beyond the purpose of the present study. A further investigation for this point is left as a future problem .

W e have succeeded to reduce enom ously the dim ension of m atrix to be diagonalized in the DMRG m ethod for the 19-vertex $m$ odel by using the ioe rule. It has been found that the $m$-dependence of the free energy show san exponential convergence even near the BKT transition point by using our $m$ ethod. An accurate result is obtained for the conform al anom aly, ie., $\mathrm{c}=1: 006(1)$ near the BK T transition point by $m$ eans of the present approach.

From the size dependence of the sm allest scaling dim ension $x_{0}^{(1)}(==2)$, we have found that $K=1: 0866$ belongs to the critical region. H ow ever, the estim ated value of $=2$ is sm aller than 1/8. On the other hand, our results for $K=1: 0500$ suggest that the value of $=2$ is larger than $1 / 8$. T hese results $m$ eans that the critical point of the 19-vertex $m$ odel is in between $K=1: 0500$ and $K=1: 0866$. A further investigation for this point is left as a fiuture problem.

F IG .1. 19 vertices perm itted by the ice rule generalized to include no arrow on a bond

FIG .2. Four arrow s surrounding a site i

F IG . 3. O ne layer which corresponds to the transfer $m$ atrix. The value of arrow $s$ incom ing to the layer is equal to the num ber of those outgoing from the layer. W hen a bond is shared by two vertices the sum $m$ ation for the variable on the bond is taken.

F IG . 4. Transfer m atrix com posed by weights $W$ and $W{ }^{(r)}$

F IG.5. C onstruction of the density matrix by a target state $\underset{N}{\sim} \underset{N}{\sim}(\mathrm{r})$ of the system. 3 and 4 are shared by two eigenvectors. Therefore we obtain a conservation rule $N_{r}(1)+2=N_{r}(1)+2$.

FIG.6. Reconstruction of $W^{(r)}$ in term $s$ of eigenvectors of the density $m$ atrix $w$ ith restriction of the value of arrow $s$.

FIG.7. m dependence of the free energy obtained by our $m$ ethod. W e use three kinds of tting functions and obtain the $s m$ allest standard deviation by an exponential function.

F IG . 8. Size dependence of the free energy of the 19-vertex model at $\mathrm{K}=1: 0866$. E stim ated value of the conform al anom aly from this result is $c=1: 006(1)$.

F IG . 9. Interaction dependence of the sm allest scaling dim ension $x_{0}^{(1)}$ .

F IG .10. $m$ dependences of $y_{m}^{(N)}$ at $K=1: 0500$ for $L=40$.

F IG.11. Size dependence of $x_{0}^{(1)}==2$ at $K=1: 0866$. The value of $x_{0}^{(1)}$ is expected to be $0: 1175$ (5) for large $L$ which is obviously below $1 / 8$ expected for the BKT transition point. The broken line shown in this gure is just guide for eyes.

F IG .12. Size dependence of $\mathrm{x}_{0}^{(1)}==2$ at $\mathrm{K}=1: 0500 . \mathrm{W}$ e observe a stronger size dependence than that at $\mathrm{K}=1: 0866$ and nd that the value is beyond $1=8$. Thebroken line show in this gure is just guide for eyes.
