## A Critique of \A Critique of Two M etals"

Philip W . Anderson and G . Baskaran Joseph Henry Laboratories of Physics Princeton University, Princeton, NJ 08544

The C ritique" [1] contains in its rst few paragraphs an elegant, if som ewhat incorrect, statem ent of the issues between us and the school which believes, alm ost religiously, in the quantum critical point as the solution to all our woes in the cuprates.

The fundam ental argum ent is presented in the second paragraph: \Ten years of work by some of the best m inds in theoretical physics have failed to produce any form aldem onstration"...of the M ott insulating state. The statem ent would be ludicrous if it were not so in uential. The proviso \at zero tem perature" is added, because of course most M ott insulators order magnetically at some nite, if often low, tem perature; the M ott insulator is not a zero-tem perature xed point, in general. Neither, for that matter, is the Fermi liquid. But one does not need a form aldem onstration (although I believe I provided that, if after M ott's original papers that was necessary, in my 1959 paper. The world, if one lifts one's eyes from the computer screen, is full of examples, and I believe that one concrete, material example is worth a million hours of computer time. Two which are very relevant to the case in point are CuSO<sub>4</sub> 5H  $_2$ O, or blue vitriol to our ancestors; and CuCl<sub>2</sub> 2H  $_2$ O. Both are examples of  $Cu^{(++)}$  and are not only insulating but transparent with a beautiful blue color, at all reasonable tem peratures they deliquesce if you get them too hot. The chloride was an elegant dem onstration case for antiferrom agnetic spin waves below its H etem perature Neel point; the sulphate was an early subject of adiabatic dem ag studies by Laughlin's colleague T. Geballe, and as far as I know is param agnetic down to very low tem peratures. Som e other less perfect cases are very in portant to us hem oglobin, which in its liquid form is familiar to all of us; and the three or four oxides of iron nust, which is m ostly goethite; hem atite, of which there are happily m ountains; and m agnetite, known to the ancients on both continents and just to show that the ground state doesn't always turn out antiferrom agnetic.

As I think Laughlin must know, the M ott insulator is a form of quantum solid, and the melting transition in He3 is our best example of a M ott transition. Our objection to trying to t cuprates into a quantum critical point scenario in the way that Z hang does becomes obvious when one tries to do the same with p-wave superconductivity and antiferrom agnetic

 $^{3}$ H e solid. There are sin ilarities which can be exploited between the short-range correlations of the quantum solid and the quantum liquid, but no connection in terms of symmetry and asymptotics. It is well-known that no critical point, even in classical theory, connects solid and liquid. The M ott transition (as is seen in V<sub>2</sub>O<sub>3</sub>) is a rst-order line ending in a critical point, classically, but this implies nothing about any relationship between the two phases at low temperatures.

I am sorry to belabor the point that there is a well-de ned insulating state in which the degrees of freedom are spins only, with an energy gap to charged excitations; and trying to connect this high-tem perature (relatively) state continuously to a metallic state by some smooth transform ation does not make any physical sense. But this seem s to be unfamiliar to the generation of physicists who did not grow up with param agnetic resonance as a major concern. It is the tragedy of M ott that although he alm ost certainly won his N obel prize for the M ott insulator, Slater, who couldn't think clearly about nite tem perature, won the publicity battle.

In the rst paragraph of the Critique the content and intent of Baskaran and my discussion is confused with our opinions on the source of superconductivity in the cuprates. Our objection to the kind of quantum critical point suggested by Zhang has nothing to do with whether it connects to a Ferm i liquid or a non-Ferm i liquid; our statem ent is that whatever the metallic state is, the low-energy excitations must be described in terms of a Ferm i surface, that is a surface in momentum space which is the locus of all of the singleparticle amplitude, and which encloses a nite volume. Unlike the relativistic eld theories and critical point theories with which Zhang is fam iliar, the excitation spectrum does not derive from uctuations of a eld which is uniform in space. The order parameter which characterizes the generalized ferm i liquid state is this surface, and its uctuations are the bosonic excitations from which quasiparticles can be constructed as solitons. The theory when bosonized thus has the kind of structure described by Haldane and others, involving uctuations of a surface in momentum space. This description is actually equally valid whether the resulting theory is FL or NFL. It has been the most serious di culty of the school which has attempted to bring the cuprates under the aegis of one form or another of eld theory | usually gauge theory | that the form s of the theories they used were not yet su ciently advanced to dealwith the Ferm isurface, which is obvious in all the experim ental manifestations of these materials.

These two underlying interm ediate-energy states are incompatible in every way. The superconductor derives from a Ferm i surface | experimentally. As Campuzano, Norm an and co-workers show, the minimum gap is always at the Luttinger Ferm i surface. The antiferrom agnet derives from a Mott insulator. The two are imm iscible and many complex

2

phenomena | such as Stripes | are found in the unstable two-phase region between them. M ott in 1956 described this fundamental instability in terms of the impossibility of adding a small number of free carriers in the magnetic case.)

Finally, we object to the statement that Zhang articulates \an alternate view in a particularly simple and elegant way ::::: that everyone can understand". We, for one, nd that the presentation, while extremely smooth, is not in any way understandable, since it is expressed in terms which we cannot accept as having relevance to the problem, using buzzwords which relate to elegant | but not particularly fruitful | treatments of critical points without reference to the actual physical content. The \anyone" certainly does not refer to us nor to any experimentalist in the eld with whom we are familiar; and I hope that there are theorists also who can see through a non-existent set of clothes.

The remainder of the \Critique" is not directed primarily at our discussion of Zhang's paper at all, but aside from some rather in moderately phrased criticisms of our work based on the rather intelevant point that the M ott state does not exist in some very restricted sense which Laughlin chooses to de ne, it seems to be presenting a new or revised version of Laughlin's own theory, so does not require our answer. Laughlin seems to be declaring closed a series of discussions of which I am sure few of the discussants would consider them selves ready to term inate in these term s.

O ne point is worth making in the context of a discussion of critical lines and crossovers. There is a crossover line associated with the H igh  $T_c$  phenom enon, which m ight be thought of as concealing an underlying zero-tem perature critical point. This is the crossover between two- and three-dimensional metallicity. O ne can hardly doubt that the great majority of H igh  $T_c$ 's show only incoherent transport along the c-direction in the normal state. It is also clear that they are all three-dimensional superconductors with c-axis supercurrents, hence coherence in the c-direction. As with all metal-insulator transitions (see above) it is not possible to de ne the insulator unequivocally except at T = 0, hence there is the presumption of a quantum critical point. But superconductivity intervenes. The c-axis infrared data demonstrate these phenomena so beautifully that it is hard to see how so many theorists can ignore the role of the third dimension. O noe one is overdoped, the two-dimensionality is gone as is  $T_c$ .
