#### Abstract

The instability condition of the non-vortex state tow ard vortex form ation is exam ined w ith in the Bogoliubov theory when a Bose $E$ instein condensate is under extemally forced rotation. The obtained critical angular velocity combined w ith the previous stability conditions for a votex yields a detailed phase diagram in the critical velocity vs the system param eter. This facilitates vortex form ation experim ents for alkali atom gases con ned in a harm onic potential.

PAC S num bers: 03.75 Fi, $67.40 \mathrm{~V} \mathrm{~s}, 67.40 \mathrm{D} \mathrm{b}, 05.30 \mathrm{Jp}$.

The quantized vortex is a m anifestation of $m$ acroscopic quantum phenom ena in quantum uids and have been observed in superconductors and super uid helium . Since the experim ental realization [1] of B ose-E instein C ondensation (BEC) in alkali-atom gases, the vortex problem in weakly interacting B ose gas has been investigated theoretically 17]. So far there is no experim ental report to nd a vortex in the present BEC system $s$ and several trials are ongoing.

It is well known that the G ross $P$ itaevskii (G P ) theory [2,[3] is valid for describing a w eakly interacting B ose system which is the case for the present alkali-atom gases of Rb and Na . B ased on the GP theory the single vortex state is discussed by several authors [4]. M ore recently Butts and R okhsar 6] describe a m any vortex state in rotating BEC, giving rise to an interesting vortex con $9-$ uration w ith m any vortices. T his $m$ ay be directly observable experim entally. T he tim e evolution of vortex is also studied by a tim e dependent form of the G P equation 7].

To investigate further fundam ental issues on a quantized vortex, we resort to the B ogoliubov theory 8,9]. $T h i s m$ icroscopic fram ew ork can describe the condensate and the non-condensate com ponents sim ultaneously, yielding the collective excitation spectrum by solving an eigenvalue equation 10 \{15].

In our series of papers 10 \{12], w e have been studying the stability problem of an isolated singly quantized vortex. The $m$ ain conclusions draw $n$ from our studies are: (1) C ontrary to the conclusion in classical papers [3, 9], BEC cannot sustain the stable vortex in an in nite sys tem at $\mathrm{T}=0$ [10]. T his conclusion coincides w ith R okhsar 14]. (2) T he nite tem perature which increases the noncondensate com ponent relative to the condensate one ef-

E-m ail: tom oya@ m p .okayam a-u ac.jp
fectively stabilizes it in a harm onically con ned system 11]. (3) A pining potential added to a ham onic conned potential also stabilizes the quantized vortex [1]. W e note that conceming the conclusion (2), Stringari 16] gives the phase diagram of the stability in a w ide range of $T$ by com paring total free energies.

In [12], apart from the above intrinsic vortex stability problem, we have discussed the vortex stability under extemally forced rotation at $T=0$. There we introduce tw o di erent criteria for stability: T he global stability is de ned by com paring the two total energies of the nonvortex state and the vortex state. T he other local stabilIty is de ned by the intrinsic stability condition for the vortex itself, evidenced by the positiveness of the low est eigenvalue. A ccording to these criteria, we obtain the phase diagram (see Fig. 7 in Ref. [12]) in the rotation angular frequency $v$ v the system param eter $a_{z}$ ( $a$ : the scattering length and $\mathrm{n}_{\mathrm{z}}$ : the particle density per unit length), which show s the three divided regions upon increasing : (A ) the vortex unstable region, (B) the single vortex stable region, and (C) the single vortex unstable region where $m$ any vortices $m$ ay appear.

In order to quantify the problem further and re ne this phase diagram, we investigate the local stability of the non-vortex state under extemal rotation. Through this study w em ay gain a valid picture of the actualnucleation process w hen w ebegin to rotate a BEC quite slow ly from zero, which has not been exam ined before. It is our hope that this study fosters the observation of a vortex in the present BEC system s.

Since the form ulation and com putational procedures are sam e as before [12], we brie y introduce the m ain equations and the notations. Let us start the follow ing $H$ am ittonian for interacting Bosons w ith the swave scattering length $a: \hat{H}_{\text {rot }}=\hat{H} \quad!\quad r$ $P_{R}(r) d r$ where $\hat{H}={ }^{R} d r^{\wedge} y(r) f \frac{h^{2} r^{2}}{2 m}+V(r) \quad g^{\wedge}(r)+$ $\frac{g^{2}}{2} \mathrm{dr}^{\wedge} \mathrm{y}(\mathrm{r})^{\wedge} \mathrm{y}(\mathrm{r})^{\wedge}(\mathrm{r})^{\wedge}(\mathrm{r})$; where $\mathrm{p}(\mathrm{r})$ is the m om entum operator, is the chem ical potential, and $V(r)$ is the con ning potential. The $m$ ass of a particle is $m$.

Follow ing the standard method, we decom pose the eld operator ${ }^{\wedge}$ as ${ }^{\wedge}(r)={ }^{\wedge}(r)+(r)$, (r) $h^{\wedge}(r) i$. W e substitute the above decom position into the above and ignore the higher order term $s$ such as ${ }^{\wedge} y \wedge \wedge{ }^{\wedge} \wedge^{\wedge} \wedge y \wedge$, and ${ }^{\wedge} \mathrm{y} \wedge_{\mathrm{P}} \wedge^{\wedge}$ tem s . Then we rew rite the operator ${ }^{\wedge}(\mathrm{r})$ as ${ }^{\wedge}(r)=P \quad{ }_{q} u_{q}(r) q \quad v_{q}(r) \underset{q}{Y}$ where q are the anninilation operators, $u_{q}(r)$ and $v_{q}(r)$ are the $w$ ave functions, and the subscript $q$ denotes the quantum num ber.

W e consider a cylindrically sym $m$ etric system and a
vortex line, if exists, passes through the center of a cylinder, coinciding $w$ th the rotation axis. $W$ e use the cylindrical coordinates: $r=(r ; j z)$. The system is trapped radially by a harm onic potentialV $(r)=\frac{1}{2} m(2 \quad)^{2} r^{2}$ and is periodic along the $z$-axis whose length is $L$.
$W$ e focus on the lowest eigenstates of the m om entum along $z$-axis and the quantum number $q$ is written as ( $q_{r} ; q$ ), where $q_{r}=1 ; 2$; and 10 ; 1 ;
The condensate wave function $(r)$ is expressed as
$(r ; ~ ; ~ z)=(r) e^{\text {iw }}$. ( (r) real) In sim ilar way, $u_{q}(r)=$ $\left.u_{q}(r) e^{i(q+w)} \quad v_{q}(r)=v_{q}(r) e^{i(q} w\right) \quad: T$ he case $w=0$ corresponds to a system w ithout a vortex and $\mathrm{w}=1$ ( $\mathrm{w}=$ 2) w ith a singly (doubly) quantized vortex.
$T$ he condensate has $N$ particles in the length $L$ and the area density is $n_{z}=N=L$. We introduce the density unit $n_{0} \quad \bar{h}=g$ where $g=4 h^{2} a=m$, the length unit ${ }^{\mathrm{P}} \overline{2 \mathrm{mh}}=\mathrm{h}$. The energy ( ${ }^{(10}$; ${ }^{0}$ ) are scaled by h . The wavefunctions ( ; u; v) are scaled by ${ }^{\mathrm{P}} \overline{\mathrm{n}_{0}}$. The angular velocity! is also scaled by 2 and the norm alized rotation is $\frac{!}{2}$. We use the norm alized values of ;"; ;u;v;r; and below.
$T$ he condition that the rst order term in ${ }^{\wedge}(r)$ of our H am iltonian vanish is the G ross P itaevskiiequation
h

$$
\begin{align*}
& \frac{d^{2}}{d r^{2}}+\frac{1}{r} \frac{d}{d r} \frac{w^{2}}{r^{2}} \\
& +\frac{r^{2}}{4}+2(r)+w \quad(r)=0 \tag{1}
\end{align*}
$$

The norm alize condition is $\mathrm{R}_{\mathrm{j}}(\mathrm{r}) \mathrm{J} \mathrm{f} r \mathrm{dr}=\frac{4 \mathrm{aN}}{\mathrm{L}}$. The condition that the $H$ am iltonian be diagonalized gives the coupled eigenvalue equations for $u_{q}(r)$, and $v_{q}(r)$ whose eigenvalue is ${ }^{\mathrm{q}}$ :

$$
\begin{align*}
& \text { h } \\
& \begin{array}{c}
\frac{d^{2}}{d r^{2}}+\frac{1}{r} \frac{d}{d r} \frac{(w+q)^{2}}{r^{2}} \\
+\frac{r^{2}}{4}+2^{2}(r)+(w+q)^{i} u_{q}(r)
\end{array} \\
& { }^{2}(\mathrm{r}) \mathrm{V}_{\mathrm{q}}(\mathrm{r})={ }_{\mathrm{q}} \mathrm{u}_{\mathrm{q}}(\mathrm{r}) \text {; }  \tag{2}\\
& \text { h } \\
& \frac{d^{2}}{d r^{2}}+\frac{1}{r} \frac{d}{d r} \quad \frac{(w \quad q)^{2}}{r^{2}} \\
& +\frac{r^{2}}{4}+2^{2}(r)+(w \quad q)^{i} v_{q}(r) \\
& { }^{2}(r) u_{q}(r)=\quad{ }_{q} V_{q}(r):
\end{align*}
$$

The norm alization conditions are $u_{p}(r) u_{q}(r) \quad v_{p}(r) v_{q}(r) \quad r d r=\frac{4 a}{L} p ; q: W$ e determ ine the signs of $q$ and " by the above nom alization condition. The set of the Eqs. (1), (2), and (3) constitute the B ogoliubov theory of our system.
$T$ he contributions of the non-condensate to the total energy is negligibly sm alland wew illuse the contribution from the condensate $\frac{E}{h N}=E N \frac{1}{4 a n_{z}} \quad\left[\quad(r)\left(\frac{d^{2}}{d r^{2}}+\right.\right.$ $\left.\left.\frac{1}{r} \frac{d}{d r} \quad \frac{w^{2}}{r^{2}}\right)(r)+\frac{r^{2}}{4} j(r) \jmath+j(r) \frac{4}{j}\right] r d r \quad w \quad$ as the total energy of the system. H ere $4 \mathrm{an}_{\mathrm{z}}$ is a dim ensionless num ber. N ote that the coe cient of ! in E is a constant.

Since the param eter $\frac{4 \mathrm{a}}{\mathrm{L}}$ in the conditions ofnorm alization does not change the follow ing results $w$ ith in the present B ogoliubov fram ework, the system is characterized by the num ber $\mathrm{an}_{\mathrm{z}}$ and the rotation.

W e solve the coupled equations; Eqs. (1), (2), and (3) for the gas of ${ }^{23} \mathrm{~N}$ a atom strapped radially by a harm onic potential of Hz . T he area density per unit length along .the z -axis is chosen to be $\mathrm{an}_{\mathrm{z}}=2: 75$ 137:5. The density pro le of the condensate ${ }^{2}(r)$ is solved from the GP equation Eq. [1). Figure] show s the pro les of the system w ith $\mathrm{w}=0 ; 1$; and 2 .

FIG.1. The particle num ber density distribution ${ }^{2}$ ( $r$ ) along the radial direction. D ashed (dotted) line is the singly (doubly) quantized vortex case $w=1(w=2)$ while solid line corresponds to the non-vortex case. To draw this gure in actual units, we use the follow ing param eters: the scattering length $\mathrm{a}=2: 75 \mathrm{~nm}, \mathrm{~m}=3: 81 \quad 10^{26} \mathrm{~kg}$, the radial trapping frequency $=100 \mathrm{~Hz}$, and $\mathrm{n}_{\mathrm{z}}=2 \quad 10^{4}=\mathrm{m}$.

The eigenvalues "'s evaluated from Eqs. (2) and (3) should be all positive relative to the condensate energy at zero for the system to be stable. This de nes the local stability of the system. In [12], we have derived the critical 's of the local stability in vortex state. T he low er criterion is ${ }_{l}^{\mathrm{L}}$ local and the upper criterion is ${ }_{\text {local }}$. For example, ${ }_{\text {local }}^{\mathrm{L}}=0: 16085$ and ${\underset{\text { local }}{\mathrm{U}}=0: 44610 \mathrm{when}}^{\mathrm{L}}$ $\mathrm{an}_{\mathrm{z}}=55$.

A lso the non-vortex state, which has the winding num ber w $=0$, could becom e locally unstable under the large extemal rotation. In other words, som e excitation level " $q$ at larger $q$ can becom e negative. These negative excitations correspond to \surface excitations" derived by D alfovo 17].

H ere, we calculate the critical in the non-vortex state to re ne the phase diagram ( $F$ ig. 7 in 12]) of stabilities. In Fig. 6 the low est edge of the eigenvalues in the non-vortex state is displayed for selected 's. There is a critical value of $w=0$ above which som e eigenvalue (s) in $q>0$ becom e(s) negative, signalling an instability of the non-vortex state. $W$ hen $<w=0$ all the eigenvalues are positive. $W$ hen $\mathrm{an}_{\mathrm{z}}=55, \mathrm{w}=0=0: 41145$. The resulting curve for $w=0$ is draw $n$ as a function of $\mathrm{an}_{\mathrm{z}}$ in

Fig.

FIG.2. The low est edge of the eigenvalues along $q$ for selected angular velocities 's. C ircles, lled circles, triangles, and lled triangles correspond to $=0,0.15,0.3$, and 0.45 respectively $\left(\mathrm{an}_{\mathrm{z}}=55\right)$. A nother eigenvalues is densely distributed at each $q$. The eigenvalues in $q<0 \mathrm{~m}$ ove up while the eigenvalues in $q>0 \mathrm{~m}$ ove down as increases. At larger some positive eigenvalue of $q$ around $q \quad 10$ becom es negative as increases. The eigenvalue at $q=0$ does not change with .

FIG.3. The four $m$ ain critical velocities 's; $\quad \begin{aligned} & \mathrm{L} \\ & \text { local }\end{aligned}$ $\underset{\text { global, }}{\mathrm{L}} \mathrm{w}=0$, and ${ }_{\text {local }}^{\mathrm{U}}$ are plotted in solid lines as functions of $\mathrm{an}_{\mathrm{z}}$. These four lines divide the whole area into ve regions (i) - (v). Each of regions are explained in text and in Fig. 4. The dashed line denotes ${ }_{\text {global }}$. The nom alization condition for Eq. (1); $j(r) j^{2} r d r=4 a n_{z} w$ ill be helpful to understand the value $\mathrm{an}_{\mathrm{z}}$.

B esides the above localstability conditions for the nonvortex and vortex states, there is the globalstability condition for . The com parison of the two energies $E$ in the system sw ith and w ithout a vortex de nes the \global stability". T he critical value betw een non-vortex state and single vortex state is ${ }_{\text {global }}^{\text {L }}$ and that betw een single vortex state ( $\mathrm{w}=1$ ) and double vortex state ( $\mathrm{w}=2$ )
 ${ }_{\text {global }}^{U}=0: 42071$ when $\mathrm{an}_{\mathrm{z}}=55$.

A s m entioned previously, the system is characterized by the number $\mathrm{an}_{\mathrm{z}}$ and the rotation. In Fig . Bwe sum $m$ arize the four critical 's; local' ${ }_{\mathrm{g}}^{\mathrm{g}} \mathrm{lobal} \mathrm{l}^{\mathrm{L}} \mathrm{w}=0$, and ${ }_{\text {local }}^{\mathrm{l}}$ as a function of $\mathrm{an}_{\mathrm{z}}$. We can divide the whole range of into ve regions, which are labeled as (i) to (v) in Fig. 3. E ach region is characterized in Fig. 4 where the schem atic energy curve for each region is show $n$.

As increases from zero,
(i) the non-vortex state is stable both locally and globally for $0 \ll \quad{ }_{\text {local }}^{\text {L }}$.
(ii) The singly quantized vortex also becom es stable locally for $\underset{\text { local }}{\mathrm{L}} \ll{ }_{\text {global }}^{\mathrm{L}}$. But the vortex state has higher energy than that in the non-vortex state. T herefore, a vortex does not nucleate spontaneously in this region.
(iii) T he energy of this vortex state becom es low er than that in the corresponding non-vortex state for ${\underset{\text { global }}{ } \lll<l}_{\text {L }}$
$<\quad w=0$. As it is seen from Fig. A, the vortex state is locally stable now, but the non-vortex state is still 0 cally stable. T herefore, the non-vortex state $m$ ust tunnel quantum $-m$ echanically through an energy barrier to the vortex state.
(iv) The vortex state can nucleate spontaneously in $\mathrm{w}=0 \ll \mathrm{l}_{\text {local }}^{\mathrm{L}}$, because the non-vortex state is unstable both locally and globally, and there is no reason for the system to stay in the non-vortex state anym ore. A vortex is now bound to appear.
(v) Since single vortex state becom es unstable, $m$ any vortices $m$ ay appear in this region: ${ }_{\text {local }}^{\mathrm{L}}<$.

It is to be noted that even above the $\underset{\text { global which is }}{\mathrm{L}}$ usually regarded as a critical angular velocity of vortex form ation, the non-vortex state rem ains locally stable in region (iii). The upper edge of (iii) region ( $w=0$ ) exceeds tw ioe of $\underset{\text { global }}{\mathrm{L}}$ at larger $\mathrm{an}_{\mathrm{z}}$. T his m eans that the angular velocity much larger than ${ }_{\text {global }}^{\mathrm{L}}$ is needed to create a vortex.
The com parison betw een $E ; w=2$ and $E ; w=1$ de nes ${ }_{\text {global }}$. T he energy $\mathrm{E} ; \mathrm{w}=2 \mathrm{~m}$ ay becom e lower than that of the state $w$ th two singly quantized vortices (this energy cannot be calculated in this axial sym $m$ etry form $u$ lation). But in the discussion below, we treat ${ }_{\text {global }}^{\mathrm{U}}$ as the (tentative) angular velocity to stabilize $m$ any vortioes states.

W e have ignored $\underset{\text { global }}{\mathrm{U}} \mathrm{F}$ igs. 会 and 4. This does not contradict w ith the above explanations in (iii) or (iv) region. But at much $s m$ aller $\mathrm{an}_{\mathrm{z}}$, the ${ }_{\mathrm{g} \text { lobal }}^{\mathrm{U}}$ appears in ( $v$ ) region. It $m$ eans that $w$ hen the $w=1$ state is unstable locally tow ard $m$ any vortices state, the energy of $\mathrm{w}=2$ vortex state is higher than that of the $\mathrm{w}=1$ state. It seem s to contradict $w$ ith the illustration in the rst line off ig. A. A possible explanation is as follow s: T he radius of $w=2$ vortex is so large that it is com parable $w$ th the system 's radius w th $\mathrm{w}=1$. T his increases $\mathrm{E}_{\mathrm{w}=2}$ and thus ${ }_{\text {global }}$.

| $\Omega$ | ENERGY | LOCAL | GLOBAL |  |
| :---: | :---: | :---: | :---: | :---: |
| $\Omega_{\text {local }}^{\mathrm{U}}$ |  | neither | vortex | (v) |
| $\begin{gathered} \Omega_{\text {local }}^{\mathrm{U}} \\ \uparrow \\ \Omega_{\mathrm{w}=0} \end{gathered}$ |  | vortex | vortex | (iv) |
| $\begin{gathered} \Omega_{\mathrm{w}=0} \\ \uparrow \\ \Omega_{\text {global }}^{\mathrm{L}} \end{gathered}$ |  | both | vortex | (iii) |
| $\begin{gathered} \Omega_{\text {global }}^{\mathrm{L}} \\ \uparrow \\ \Omega_{\text {local }}^{\mathrm{L}} \end{gathered}$ |  | both | non-vortex | (ii) |
| $\begin{gathered} \Omega_{\text {local }}^{\mathrm{L}} \\ \uparrow \\ 0 \end{gathered}$ |  | non-vortex <br> (state is locally stable) | non-vortex <br> (state is <br> globally <br> stable) | (i) |

FIG.4. From left to right colum $n$, the ranges of , the schem atic energy con guration near non-vortex and vortex states, the localstability, and the globalstability. T he num ber of the last colum $n$ corresponds to that of $F i g$. 3.

In order to obtain $m$ ore insights into the vortex stabilIty problem in the B ose E instein condensation of alkali atom gases con ned in a harm onic potential, w e have extended our previous work 10,11 ] to the case where the cylindrical system is under foroed rotation.

O ur calculation is done within the fram ew ork of the non-selfconsistent B ogoliubov theory and yielded the vortex stability phase diagram shown in F ig. 3. T he stability of the vortex state is exam ined by the two di erent w ays. $T$ hey are the localstability and the globalstability. T he localstability is evaluated both in single vortex state and in non-vortex state. T hese stability conditions yield the whole phase diagram of the vortex stability problem shown in F ig. 4. In addition to the usual critical angular velocity global, we quantitatively obtain the values of $w=0$ and global which describes the instability of the non-vortex state tow ard the vortex state.

The previous cases 10,11$]$, which are consistent $w$ ith the present results, correspond to the $=0$ axis in Fig . B where the vortex is intrinsically unstable. $T$ his instability is seen to occupy a nite range of , not only the isolated line con ned at $=0$, for various densities $n_{z}$ and the scattering lengths a as another axis. It is found that the angular velocity much larger than $\mathrm{L}_{\text {global }}$ is needed to create a vortex. W ith the previous nite tem perature calculations [11], the present calculation concludes that alkali atom Bose gases in BEC can sustain and exhibit the stable vortex in certain range of tem perature and extemal rotation.

There are $m$ any problem $s$ left conceming the vortices in BEC.About the appropriate value of angular velocity, we need the calculations in full three dim ension geom etry. T he process to gain/lost the vortex core w ill be described better if we can treat the tim e evolution of both the condensate and the non-condensate [18]. T he w ay to give the angular $m$ om entum to the condensate (or cloud of atom $s$ before condensation) is the im portant problem for experim entalists 19]. It is our hope that this study fosters the observation of a vortex in the present BEC system s .

T he authors thank L. P itaevskiifor raising an adequate and tim ely question regarding to the instability of the non-vortex state, which leads to the present w ork.
