# Dichotomy Theorems for Alternation-Bounded Quantified Boolean Formulas^ 

Edith Hemaspaandra<br>Department of Computer Science, Rochester Institute of Technology, Rochester, NY 14623, U.S.A.,<br>eh@cs.rit.edu

#### Abstract

In 1978, Schaefer proved his famous dichotomy theorem for generalized satisfiability problems. He defined an infinite number of propositional satisfiability problems, showed that all these problems are either in P or NP-complete, and gave a simple criterion to determine which of the two cases holds. This result is surprising in light of Ladner's theorem, which implies that there are an infinite number of complexity classes between P and NP-complete (under the assumption that P is not equal to NP). Schaefer also stated a dichotomy theorem for quantified generalized Boolean formulas, but this theorem was only recently proven by Creignou, Khanna, and Sudan, and independently by Dalmau: Determining truth of quantified Boolean formulas is either PSPACE-complete or in P . This paper looks at alternation-bounded quantified generalized Boolean formulas. In their unrestricted forms, these problems are the canonical problems complete for the levels of the polynomial hierarchy. In this paper, we prove dichotomy theorems for alternation-bounded quantified generalized Boolean formulas, by showing that these problems are either $\Sigma_{i}^{p}$-complete or in P, and we give a simple criterion to determine which of the two cases holds. This is the first result that obtains dichotomy for an infinite number of classes at once.

Keywords: quantified Boolean formulas, computational complexity, Boolean constraints, dichotomy, polynomial hierarchy

## 1 Introduction

In 1978, Schaefer proved his famous dichotomy theorem for generalized satisfiability problems. He defined an infinite number of propositional satisfiability problems (nowadays often called Boolean constraint satisfaction problems), showed that all these problems are either in P or NP-complete, and gave a simple criterion to determine which of the two cases holds. This result is surprising in light of Ladner's theorem, which implies that there are an infinite number of

[^0]complexity classes between P and NP-complete (under the assumption that P is not equal to NP).

To make the discussion more concrete, we will quickly define what a constraint is and what a constraint problem is. Formal definitions can be found in Section 2 In this paper, we will be talking about Boolean constraints. See for example Feder and Vardi FV98 for a discussion about general constraint satisfaction problems.

A constraint is a Boolean operator of fixed arity, specified as a Boolean function. For $C$ a constraint of arity $k$, and $x_{1}, \ldots, x_{k}$ propositional variables (or constants), $C\left(x_{1}, \ldots, x_{k}\right)$ is a constraint application of $C$. For example, $\lambda x y .(x \vee y)$ is a constraint, and $x_{1} \vee x_{2}$ is a constraint application of this constraint. Each finite set of constraints $\mathcal{C}$ gives rise to a satisfiability problem $\operatorname{SAT}(\mathcal{C}): \operatorname{SAT}(\mathcal{C})$ is the problem of, given a set of constraint applications of $\mathcal{C}$, determining whether this set has a satisfying assignment. We can view a set of constraint applications as a CNF formula. For example, 2CNF-SAT corresponds to $\operatorname{SAT}(\{\lambda x y .(x \vee y), \lambda x y .(x \vee \bar{y}), \lambda x y \cdot(\bar{x} \vee \bar{y})\})$.

Using constraint terminology, Schaefer's dichotomy theorem Sch78 can now be formulated as follows: For any finite set of constraints $\mathcal{C}$, either $\operatorname{SAT}(\mathcal{C})$ is in P , or $\operatorname{SAT}(\mathcal{C})$ is NP-complete.

In recent years, dichotomy theorems (or dichotomy-like theorems) have been obtained for a number of other problems about logics. For example, such theorems have be obtained for the problem of determining whether a formula has exactly one satisfying assignment Jub99, the problem of finding a satisfying assignment that satisfies a maximum number of constraint applications Cre95, the problem of computing the number of satisfying assignments [CH96, the problem of finding the minimal satisfying assignment KK03, the inverse satisfiability problem [KS98, the equivalence problem BHRV02], the isomorphism problem BHRV04, and the complexity of propositional circumscription KK01. Khanna, Sudan, Trevisan, and Williamson examined the approximability of some of these problems KSTW01]. Consult the excellent monograph CKS01 for an almost completely up-to-date overview of dichotomy theorems for Boolean constraint problems.

Schaefer also stated a dichotomy theorem for quantified generalized formulas (or, equivalently, quantified sets of constraint applications), but this theorem was only recently proven by Creignou, Khanna, and Sudan CKS01, and independently by Dalmau Dal97: Depending on the underlying finite set of constraints, these problems are either PSPACE-complete or in P.

This paper looks at alternation-bounded quantified sets of constraint applications. In their unrestricted forms, alternation-bounded quantified Boolean formulas are the canonical problems complete for the levels of the polynomial hierarchy. In this paper, we prove dichotomy theorems for alternation-bounded quantified sets of constraint applications, by showing that these problems are either $\Sigma_{i}^{p}$-complete or in P , and we give a simple criterion to determine which of the two cases holds.

The importance of these results is two-fold. First of all, unlike all previous results, our result obtains dichotomy for an infinite number of classes at once (namely, we prove dichotomy for each level of the polynomial hierarchy). Secondly, Schaefer's dichotomy theorem has proven very successful as a tool for proving NP-hardness. After all, his theorem supplies us with an infinite number of NP-complete variations of the already often-used satisfiability problem. We expect that our dichotomy theorems will likewise be useful in proving problems hard for higher levels of the polynomial hierarchy. Though there are not as many natural problems complete for higher levels of the polynomial hierarchy as for NP, there are in fact quite a few. See the survey by M. Schaefer and Umans SU02.

The rest of this paper is organized as follows. In Section 2 we give the formal definitions of constraints, constraint applications, complexity classes, and the various constraint problems that we are interested in, and we will formally state Schaefer's dichotomy theorem and the dichotomy theorem for quantified sets of constraint applications. In Section 3 we will prove the dichotomy theorems for alternation-bounded quantified constraint problems.

## 2 Preliminaries

### 2.1 Constraints

We will use the terminology and notation from CKS01. ${ }^{1}$
Definition 1. 1. A constraint $C$ is a Boolean function from $\{0,1\}^{k}$ to $\{0,1\}$, where $k>0 . k$ is the arity of $C$.
2. If $C$ is a constraint of arity $k$, and $z_{1}, z_{2}, \ldots, z_{k}$ are (not necessarily distinct) variables, then $C\left(z_{1}, z_{2}, \ldots, z_{k}\right)$ is a constraint application of $C$.
3. If $C$ is a constraint of arity $k$, and for $1 \leq i \leq k, z_{i}$ is a variable or a constant (0 or 1), then $C\left(z_{1}, z_{2}, \ldots, z_{k}\right)$ is a constraint application of $C$ with constants.
When we want to be explicit about the variables occurring in a set of constraint applications $S$, we will write $S\left(x_{1}, \ldots, x_{n}\right)$, to denote that the variables of $S$ are in $\left\{x_{1}, \ldots, x_{n}\right\}$. If we also want to be explicit about constants, we will write $S\left(x_{1}, \ldots, x_{n}, 0,1\right)$.

Schaefer's generalized satisfiability problems can now be defined formally, using constraint terminology.

Definition 2. Let $\mathcal{C}$ be a finite set of constraints.

1. $\operatorname{SAT}(\mathcal{C})$ is the problem of deciding whether a given set $S$ of constraint applications of $\mathcal{C}$ satisfiable, i.e., whether there exists an assignment to the variables of $S$ that satisfies every constraint application in $S$.

[^1]2. $\operatorname{SAT}_{c}(\mathcal{C})$ is the problem of deciding whether given set $S$ of constraint applications of $\mathcal{C}$ with constants is satisfiable.

As mentioned in the introduction, Schaefer proved that all these problems are either in P or NP-complete. It is also easy to determine which of these two cases hold. This depends on simple properties of the constraints.

Definition 3. Let $C$ be a constraint.
$-C$ is 0 -valid if $C(0, \ldots, 0)=1$.
$-C$ is 1 -valid if $C(1, \ldots, 1)=1$.

- $C$ is Horn (or weakly negative) if $C$ is equivalent to a CNF formula where each clause has at most one positive variable.
$-C$ is anti-Horn (or weakly positive) if $C$ is equivalent to a CNF formula where each clause has at most one negative variable.
- $C$ is bijunctive if $C$ is equivalent to a 2CNF formula.
$-C$ is affine if $C$ is equivalent to a XOR-CNF formula.
$-C$ is complementive (or C-closed) if for every $s \in\{0,1\}^{k}, C(s)=C(\bar{s})$, where $k$ is the arity of $C$ and $\bar{s}=\left(1-s_{1}\right)\left(1-s_{2}\right) \cdots\left(1-s_{k}\right)$ for $s=s_{1} s_{2} \cdots s_{k}$.

Let $\mathcal{C}$ be a finite set of constraints. We say $\mathcal{C}$ is 0-valid, 1-valid, Horn, anti-Horn, bijunctive, affine, or complementive if every constraint $C \in \mathcal{C}$ is 0-valid, 1-valid, Horn, anti-Horn, bijunctive, affine, or complementive, respectively.

Schaefer's theorem can now be stated as follows.
Theorem 4 (Schaefer [Sch78]). Let $\mathcal{C}$ be a finite set of constraints.

1. If $\mathcal{C}$ is 0-valid, 1-valid, Horn, anti-Horn, affine, or bijunctive, then $\operatorname{SAT}(\mathcal{C})$ is in P ; otherwise, $\operatorname{SAT}(\mathcal{C})$ is NP -complete.
2. If $\mathcal{C}$ is Horn, anti-Horn, affine, or bijunctive, then $\operatorname{SAT}_{c}(\mathcal{C})$ is in P ; otherwise, $\operatorname{SAT}_{c}(\mathcal{C})$ is NP-complete.

### 2.2 Quantified constraint applications

QBF is the problem of deciding whether a given fully quantified Boolean formula is true. QBF is PSPACE-complete SM73. This problem remains PSPACEcomplete if we restrict the Boolean formula to be in 3CNF Sto77. We use the following definition for quantified sets of constraint applications.

Definition 5 ([CKS01]). Let $\mathcal{C}$ be a finite set of constraints. $A$ quantified $\mathcal{C}$ expression [with constants] is an expression of the form $Q_{1} x_{1} Q_{2} x_{2} \ldots Q_{n} x_{n} S\left(x_{1}, \ldots, x_{n}\right)$, where $S$ is a set of constraint applications of $\mathcal{C}$ [with constants], and $Q_{i} \in\{\exists, \forall\}$ for all $i$.

We now define the constraint analogs of QBF.

## Definition 6 ([CKS01], Definition 3.9).

1. $\operatorname{QSAT}(\mathcal{C})$ is the problem of deciding whether a given quantified $\mathcal{C}$ expression is true.
2. $\operatorname{QSAT}_{c}(\mathcal{C})$ is the problem of deciding whether a quantified $\mathcal{C}$ expression with constants is true.
$\operatorname{QSAT}(\mathcal{C})$ and $\operatorname{QSAT}_{c}(\mathcal{C})$ exhibit dichotomy as well. Remarkably, if $\operatorname{SAT}_{c}(\mathcal{C})$ is in P , then so are $\operatorname{QSAT}(\mathcal{C})$ and $\operatorname{QSAT}_{c}(\mathcal{C})$. In all other cases, $\operatorname{SAT}_{c}(\mathcal{C})$ is NP-complete and $\operatorname{QSAT}(\mathcal{C})$ and $\operatorname{QSAT}_{c}(\mathcal{C})$ are PSPACE-complete.

Theorem 7 ([Sch78, CKS01, Dal97]). Let $\mathcal{C}$ be a finite set of constraints. If $\mathcal{C}$ is Schaefer, then $\operatorname{QSAT}(\mathcal{C})$ and $\operatorname{QSAT}_{c}(\mathcal{C})$ are in P ; otherwise, $\operatorname{QSAT}(\mathcal{C})$ and $\operatorname{QSAT}_{c}(\mathcal{C})$ are PSPACE-complete.

The history behind this theorem is rather interesting. The dichotomy theorem for $\operatorname{QSAT}_{c}(\mathcal{C})$ was stated without proof by Schaefer Sch78. Schaefer mentioned that the proof relies on the result that the set of true quantified 3CNF formulas is PSPACE-complete. Creignou et al. proved Theorem 7 in CKS01. The proofs of the PSPACE lower bounds for $\operatorname{QSAT}_{c}(\mathcal{C})$ are similar to the NP-hardness proofs for $\operatorname{SAT}_{c}(\mathcal{C})$. It is shown by Creignou et al. CKS01, and independently by Dalmau Dal97, that $\operatorname{QSAT}_{c}(\mathcal{C})$ polynomial-time many-one reduces to $\operatorname{QSAT}(\mathcal{C})$.

### 2.3 The Polynomial Hierarchy and Constraints

The polynomial-time hierarchy (polynomial hierarchy or PH for short) was defined by Meyer and Stockmeyer MS72].

Definition 8 ([MS72]).
$-\Sigma_{0}^{p}=\Pi_{0}^{p}=\mathrm{P}$.
$-\Sigma_{i+1}^{p}=\mathrm{NP}^{\Sigma_{i}^{p}}$
$-\Pi_{i+1}^{p}=\operatorname{coNP}^{\Sigma_{i}^{p}}$
$\operatorname{QSAT}_{i}$ is the set of all true fully quantified boolean formulas with $i-1$ quantifier alternations, starting with an $\exists$ quantifier. For all $i \geq 1, \operatorname{QSAT}_{i}$ is complete for $\Sigma_{i}^{p}$ SM73]. These problems remain $\Sigma_{i}^{p}$-complete if we restrict the Boolean formula to be in 3CNF for $i$ odd and to 3DNF for $i$ even Wra77.

To generalize QSAT $_{i}$ to arbitrary sets of constraints, it is important to realize that 3CNF formulas correspond to sets of constraint applications, but 3DNF formulas do not. Of course, a 3DNF formula is the negation of a 3CNF formula. For $i$ even, we can view QSAT $_{i}$ as the set of all false fully quantified boolean formulas of the form $\forall X_{1} \exists X_{2} \cdots \exists X_{i} \phi\left(X_{1}, \ldots, X_{k}\right)$, where $X_{1}, \ldots, X_{k}$ are sets of variables. Restricting $\phi$ to 3CNF in this view of $\operatorname{QSAT}_{i}$ will still be $\Sigma_{i}^{p}$-complete. We can now generalize QSAT $_{i}$ to arbitrary sets of constraints.

Definition 9. Let $\mathcal{C}$ be a finite set of constraints.

- For all $i \geq 1$, a $\Sigma_{i}(\mathcal{C})$ expression [with constants] is an expression of the form $\exists X_{1} \forall X_{2} \cdots Q_{i} X_{i} S\left(X_{1}, \ldots, X_{i}\right)$, where $S$ is a set of constraint applications of $\mathcal{C}$ [with constants]. Here $X_{1}, X_{2}, \ldots$ are sets of variables.
- For all $i \geq 1$, a $\Pi_{i}(\mathcal{C})$ expression [with constants] is an expression of the form $\forall X_{1} \exists X_{2} \cdots Q_{i} X_{i} S\left(X_{1}, \ldots, X_{i}\right)$, where $S$ is a set of constraint applications of $\mathcal{C}$ [with constants].
Definition 10. Let $\mathcal{C}$ be a set of constraints. Let $i \geq 1$.

1. For $i$ odd, $\operatorname{QSAT}_{i}(\mathcal{C})$ is the problem of deciding whether a given $\Sigma_{i}(\mathcal{C})$ expression is true, and $\operatorname{QSAT}_{i, c}(\mathcal{C})$ is the problem of deciding whether a given $\Sigma_{i}(\mathcal{C})$ expression with constants is true.
2. For $i$ even, $\operatorname{QSAT}_{i}(\mathcal{C})$ is the problem of deciding whether a given $\Pi_{i}(\mathcal{C})$ expression is false, and $\operatorname{QSAT}_{i, c}(\mathcal{C})$ is the problem of deciding whether a given $\Pi_{i}(\mathcal{C})$ expression with constants is false.

## 3 Dichotomy in the Polynomial Hierarchy

The main proof technique for lower bounds on constraint problems is to show that the problems can simulate an already-known-to-be hard problem. The freedom allowed in the simulations depends on the type of problem considered. For example, for satisfiability problems, we are allowed to introduce existentially quantified auxiliary variables. In CKS01 terminology, this is known as a "perfect implementation."

Definition 11 ([CKS01]).

1. A set of constraint applications $S(X, Y)$ perfectly implements constraint $C$ iff $C(X) \equiv \exists Y S(X, Y)$.
2. A set of constraints $\mathcal{D}$ perfectly implements constraint $C$ iff there exists a set of constraint applications of $\mathcal{D}$ that perfectly implements $C$.

Perfect implementations work well for satisfiability problems.

## Lemma 12 (CKS01], 5.12, 5.16).

1. If $\operatorname{SAT}(\mathcal{C})$ is $\mathrm{NP}-h a r d$ and every constraint in $\mathcal{C}$ can be perfectly implemented by $\mathcal{D}$, then $\operatorname{SAT}(\mathcal{D})$ is also NP-hard.
2. If $\operatorname{QSAT}(\mathcal{C})$ is PSPACE-hard and every constraint in $\mathcal{C}$ can be perfectly implemented by $\mathcal{D}$, then $\operatorname{QSAT}(\mathcal{D})$ is also PSPACE-hard.

It is easy to see that the same construction works for PH as well.
Lemma 13. For all $i \geq 2$, if $\operatorname{QSAT}_{i}(\mathcal{C})$ is $\Sigma_{i}^{p}$-hard and every constraint in $\mathcal{C}$ can be perfectly implemented by $\mathcal{D}$, then $\operatorname{QSAT}_{i}(\mathcal{D})$ is also $\sum_{i}^{p}$-hard.

Proof. Much like the corresponding proof of Lemma 12 for $\operatorname{QSAT}(\mathcal{C})$. Let $Q_{1} X_{1} Q_{2} X_{2} \cdots \exists X_{i} S\left(X_{1}, \ldots, X_{i}\right)$ be a $\Sigma_{i}(\mathcal{C})$ expression if $i$ is odd and a $\Pi_{i}(\mathcal{C})$ expression if $i$ is even. For every constraint application $A(Y) \in S$, replace $A(Y)$ by a set of constraint applications $U(Y, Z)$ of $\mathcal{D}$ such that $A(Y) \equiv \exists Z U(Y, Z)$. Make sure that the $Z$ is a set of new variables, and that all introduced sets of new variables are disjoint. Let $\widehat{S}$ be the resulting set of constraint applications and let $\widehat{Z}$ be the set of all new variables. Then $Q_{1} X_{1} Q_{2} X_{2} \cdots \exists X_{i} S\left(X_{1}, \ldots, X_{i}\right)$ is true iff $Q_{1} X_{1} Q_{2} X_{2} \cdots \exists X_{i} \exists \widehat{Z} \widehat{S}\left(X_{1}, \ldots, X_{i}, \widehat{Z}\right)$ is true.

The dichotomy theorem for the case with constants now follows much in the same way as in the case for general quantified expressions.

Theorem 14. Let $\mathcal{C}$ be a finite set of constraints and let $i \geq 2$. If $\mathcal{C}$ is Horn, anti-Horn, affine, or bijunctive, then $\operatorname{QSAT}_{i, c}(\mathcal{C})$ is in P ; otherwise, $\mathrm{QSAT}_{i, c}(\mathcal{C})$ is $\Sigma_{i}^{p}$-complete.

Proof. The polynomial-time cases follow immediately from the fact that if $\mathcal{C}$ is Horn, anti-Horn, affine, or bijunctive, then even $\operatorname{QSAT}_{c}(\mathcal{C})$ is in P (Theorem[7). It is also immediate that $\operatorname{QSAT}_{i, c}(\mathcal{C})$ is in $\Sigma_{i}^{p}$.

It remains to show the $\Sigma_{i}^{p}$ lower bounds. We closely follow the proof that $\operatorname{QSAT}(\mathcal{C})$ is PSPACE-hard from CKS01, Theorem 6.12].

Recall from Section 2.3 that the 3CNF version of $\mathrm{QSAT}_{i}$ is complete for $\Sigma_{i}^{p}$. In constraint terminology, $\operatorname{QSAT}_{i}(\mathcal{D})$ is complete for $\Sigma_{i}^{p}$, where $\mathcal{D}=\{\lambda x y z . x \vee$ $y \vee z, \lambda x y z . x \vee y \vee \bar{z}, \lambda x y z . x \vee \bar{y} \vee \bar{z}, \lambda x y z . \bar{x} \vee \bar{y} \vee \bar{z}\}$.

In addition, the constraint One-in-Three (which is defined as the ternary Boolean function that is true if and only if exactly one of its three arguments is true) can perfectly implement any ternary function CKS01. Using Lemma 13 it follows that $\operatorname{QSAT}_{i}(\{$ One-in-Three $\})$ is $\Sigma_{i}^{p}$-hard. If $\mathcal{C}$ is not Horn, not anti-Horn, not affine, and not bijunctive, then $\mathcal{C} \cup\{\lambda x . \bar{x}, \lambda x . x\}$ perfectly implements One-in-Three CKS01. It follows from Lemma 13 that $\operatorname{QSAT}_{i}(\mathcal{C} \cup\{\lambda x . \bar{x}, \lambda x . x\})$ is $\Sigma_{i}^{p}$-hard. This implies that $\operatorname{QSAT}_{i, c}(\mathcal{C})$ is $\Sigma_{i}^{p}$-hard: Let $Q_{1} X_{1} Q_{2} X_{2} \cdots \exists X_{i} S\left(X_{1}, \ldots, X_{i}\right)$ be a quantified $\mathcal{C} \cup\{\lambda x . x, \lambda x . \bar{x}\}$ expression. If there exists a variable $x$ such that both $x$ and $\bar{x}$ are in $S$, then $S \equiv 0$. In that case, replace all of $S$ by 0 . Otherwise, for every variable $x$ such that $x \in S$ and $\bar{x} \notin S$, replace this variable by 1 , and remove $x$ from $S$. For every variable $x$ such that $\bar{x} \in S$ and $x \notin S$, replace $x$ by 0 and remove $\bar{x}$ from $S$. Call the resulting set of constraint applications $\widehat{S}$. Then $\widehat{S}$ is a set of constraint applications of $\mathcal{C}$ with constants, and $Q_{1} X_{1} Q_{2} X_{2} \cdots \exists X_{i} S\left(X_{1}, \ldots, X_{i}\right)$ is true iff $Q_{1} X_{1} Q_{2} X_{2} \cdots \exists X_{i} \widehat{S}\left(X_{1}, \ldots, X_{i}\right)$ is true.

Far more effort is needed to prove the lower bounds for the case without constants. Indeed, the remainder of this paper is dedicated to establishing this result.

Theorem 15. Let $\mathcal{C}$ be a finite set of constraints and let $i \geq 2$. If $\mathcal{C}$ is Horn, anti-Horn, affine, or bijunctive, then $\operatorname{QSAT}_{i}(\mathcal{C})$ is in P ; otherwise, $\operatorname{QSAT}_{i}(\mathcal{C})$ is $\Sigma_{i}^{p}$-complete.

Proof. The upper bounds follow from Theorem 14 For the remainder of this proof, suppose that $\mathcal{C}$ is not Horn, not anti-Horn, not affine, and not bijunctive. We need to show that $\operatorname{QSAT}_{i}(\mathcal{C})$ is $\Sigma_{i}^{p}$-hard. Without loss of generality, we assume that no constraint in $\mathcal{C}$ is a constant function. (Since such constraints are bijunctive, we can simply remove them.)

We will prove that $\operatorname{QSAT}_{i}(\mathcal{C})$ is $\Sigma_{i}^{p}$-hard by a case distinction that depends on whether or not $\mathcal{C}$ is 0 -valid, 1 -valid, and/or complementive. In all cases, we will reduce $\operatorname{QSAT}_{i, c}(\mathcal{C})$ to $\operatorname{QSAT}_{i}(\mathcal{C})$.
$\mathcal{C}$ is $\mathbf{0}$-valid and not complementive In this case, $\mathcal{C}$ perfectly implements the constraint $\lambda x y . \bar{x} \vee y$ [CKS01, Lemma 5.41].
As a starting point, we will first review the reduction from $\operatorname{QSAT}_{c}(\mathcal{C})$ to $\operatorname{QSAT}(\mathcal{C})$ from CKS01 Theorem 6.12] for the case that $\mathcal{C}$ is 0 -valid and not complementive. The main observation needed for this reduction is that $\forall y\{\bar{f} \vee y, \bar{y} \vee t\}$ is equivalent to $\bar{f} \wedge t$.
Let $Q_{1} x_{1} \cdots Q_{n} x_{n} S\left(x_{1}, \ldots, x_{n}, 0,1\right)$ be a quantified $\mathcal{C}$ expression with constants. Using the observation above, it is easy to see that this expression is equivalent to the quantified $\mathcal{C} \cup\{\lambda x y . \bar{x} \vee y\}$ expression $\exists f \exists t \forall y Q_{1} x_{1} \cdots Q_{n} x_{n}$ $\left[S\left(x_{1}, \ldots, x_{n}, f, t\right) \cup\{\bar{f} \vee y, \bar{y} \vee t\}\right]$.
Thus, $\operatorname{QSAT}(\mathcal{C} \cup\{\lambda x y . \bar{x} \vee y\})$ is PSPACE-hard. Since $\mathcal{C}$ perfectly implements $\lambda x y \cdot \bar{x} \vee y$, it follows by Lemma 12 that $\operatorname{QSAT}(\mathcal{C})$ is PSPACE-hard.
Note that this construction does not prove that $\operatorname{QSAT}_{i}(\mathcal{C})$ is $\Sigma_{i}^{p}$-complete, since the construction turns a $\Sigma_{i}(\mathcal{C})$ expression with constants into a $\Sigma_{i+2}(\mathcal{C})$ expression for $i$ odd, and a $\Pi_{i}(\mathcal{C})$ expression with constants into a $\Sigma_{i+1}(\mathcal{C})$ expression for $i$ even.
However, it is easy to see that we can place $\exists f \exists t \forall y$ anywhere in the quantifier string, as long as $\exists f$ and $\exists t$ precede $\forall y$. This implies that, as long as the original expression contains existential quantifiers followed by universal quantifiers, we obtain the required reduction. Formally, for $i>2$, we reduce $\operatorname{QSAT}_{i, c}(\mathcal{C})$ to $\operatorname{QSAT}_{i}(\mathcal{C})$, by mapping $Q_{1} X_{1} \cdots \exists X_{i-2} \forall X_{i-1} \exists X_{i} S\left(X_{1}, \ldots, X_{i}, 0,1\right)$ to $Q_{1} X_{1} \cdots \exists X_{i-2} \exists f \exists t \forall y \forall X_{i-1} \exists X_{i}\left[S\left(X_{1}, \ldots, X_{i}, f, t\right) \cup\{\bar{f} \vee y, \bar{y} \vee t\}\right]$.
Since $\mathcal{C}$ is 0 -valid, we know from Theorem 4 that, under the assumption that $\mathrm{P} \neq \mathrm{NP}, \operatorname{QSAT}_{i, c}(\mathcal{C})$ is not reducible to $\operatorname{QSAT}_{i}(\mathcal{C})$ for $i=1$. It remains to handle the case that $i=2$.
Let $\forall X_{1} \exists X_{2} S\left(X_{1}, X_{2}, 0,1\right)$ be a $\Pi_{2}(\mathcal{C})$ expression with constants. We claim that this expression is equivalent to the following $\Pi_{2}(\mathcal{C} \cup\{\lambda x y . \bar{x} \vee y\})$ expression:

$$
\forall X_{1} \forall y \forall z \exists f \exists t \exists X_{2}\left[S\left(X_{1}, X_{2}, f, t\right) \cup\{\bar{f} \vee y, \bar{z} \vee t\}\right]
$$

For the proof, note that

$$
\begin{array}{rl}
\forall X_{1} \forall y \forall z \exists f \exists t \exists X_{2} & {\left[S\left(X_{1}, X_{2}, f, t\right) \cup\{\bar{f} \vee y, \bar{z} \vee t\}\right]} \\
\text { iff } & \\
\forall X_{1} \exists f \exists t \exists X_{2} & {\left[S\left(X_{1}, X_{2}, f, t\right) \cup\{\bar{f} \vee 0,1 \vee t\}\right],} \\
\forall X_{1} \exists f \exists t \exists X_{2} & {\left[S\left(X_{1}, X_{2}, f, t\right) \cup\{\bar{f} \vee 0,0 \vee t\}\right],} \\
\forall X_{1} \exists f \exists t \exists X_{2} & {\left[S\left(X_{1}, X_{2}, f, t\right) \cup\{\bar{f} \vee 1,1 \vee t\}\right], \text { and }} \\
\forall X_{1} \exists f \exists t \exists X_{2} & {\left[S\left(X_{1}, X_{2}, f, t\right) \cup\{\bar{f} \vee 1,0 \vee t\}\right]} \\
\text { iff } & \\
\forall X_{1} \exists f \exists t \exists X_{2} & {\left[S\left(X_{1}, X_{2}, f, t\right) \cup\{\bar{f}, t\}\right]} \\
\text { iff } & \\
\forall X_{1} \exists X_{2} & S\left(X_{1}, X_{2}, 0,1\right)
\end{array}
$$

Note that this construction can be generalized to all $i \geq$ 2, by mapping $Q_{1} X_{1} \cdots \exists X_{i-2} \forall X_{i-1} \exists X_{i} S\left(X_{1}, \ldots, X_{i}, 0,1\right)$ to $Q_{1} X_{1} \cdots \forall X_{i-1} \forall y \forall z \exists f \exists t \exists X_{i}\left[S\left(X_{1}, \ldots, X_{i}, f, t\right) \cup\{\bar{f} \vee y, \bar{z} \vee t\}\right]$.
$\mathcal{C}$ is 1 -valid and not complementive In this case, we could simply state that the proof is similar to the proof of the case that $\mathcal{C}$ is 0 -valid and not complementive. But rather than making the reader work through the previous case to see that this is actually true, we will prove a theorem (Theorem 17) which relates satisfiability problems for sets of constraint applications of $\mathcal{C}$ [with constants] to the satisfiability problems where the set of constraints is replaced by a type of "complement." This theorem immediately implies the current case and will also be useful in the case that $\mathcal{C}$ is complementive. We start with some definitions.

Definition 16. 1. Let $C$ be a k-ary constraint. Define constraint $C^{c}$ as follows. For all $s \in\{0,1\}^{k}, C^{c}(s)=C(\bar{s})$, where, as in the definition of complementive, $\bar{s}=\left(1-s_{1}\right)\left(1-s_{2}\right) \cdots\left(1-s_{k}\right)$ for $s=s_{1} s_{2} \cdots s_{k}$. Note that $C$ is complementive iff $C=C^{c}$.
2. Let $\mathcal{C}$ be a finite set of constraints. Define the set of constraints $\mathcal{C}^{c}$ as $\mathcal{C}^{c}=\left\{C^{c} \mid C \in \mathcal{C}\right\}$.
3. For $S$ a set of constraint applications of $\mathcal{C}$ with constants, define $S^{c}$ as $\left\{C^{c}\left(z_{1}, \ldots, z_{k}\right) \mid C\left(z_{1}, \ldots, z_{k}\right) \in S\right\}$, where each $z_{i}$ is a variable or a constant.

Theorem 17. 1. For all $i \geq 1, \operatorname{QSAT}_{i}(\mathcal{C}) \equiv{ }_{m}^{p} \operatorname{QSAT}_{i}\left(\mathcal{C}^{c}\right)$ and $\operatorname{QSAT}_{i, c}(\mathcal{C}) \equiv{ }_{m}^{p} \operatorname{QSAT}_{i, c}\left(\mathcal{C}^{c}\right)$.
2. $\operatorname{QSAT}(\mathcal{C}) \equiv{ }_{m}^{p} \operatorname{QSAT}\left(\mathcal{C}^{c}\right)$ and $\operatorname{QSAT}_{c}(\mathcal{C}) \equiv_{m}^{p} \operatorname{QSAT}_{c}\left(\mathcal{C}^{c}\right)$.

This theorem follows immediately from the following lemma.
Lemma 18. Let $\mathcal{C}$ be a finite set of constraints and let $Q_{1} x_{1} \cdots Q_{n} x_{n} S\left(x_{1}, \ldots, x_{n}, 0,1\right)$ be a quantified $\mathcal{C}$ expression with constants. Then $Q_{1} x_{1} \cdots Q_{n} x_{n} S\left(x_{1}, \ldots, x_{n}, 0,1\right)$ is true if and only if $Q_{1} x_{1} \cdots Q_{n} x_{n} S^{c}\left(x_{1}, \ldots, x_{n}, 1,0\right)$ is true.

Proof. The proof is by induction on $n$, the number of variables in $S$. For $n=0$, by definition of $S^{c}, S(0,1)=S^{c}(1,0)$. Now let $n>0$, and suppose the claim holds for $n-1$.
If $Q_{1}=\forall$, then $Q_{1} x_{1} \cdots Q_{n} x_{n} S\left(x_{1}, \ldots, x_{n}, 0,1\right)$ is true if and only if both $Q_{2} x_{2} \cdots Q_{n} x_{n} S\left(0, x_{2}, \ldots, x_{n}, 0,1\right)$ and $Q_{2} x_{2} \cdots Q_{n} x_{n} S\left(1, x_{2}, \ldots, x_{n}, 0,1\right)$ are true. By induction, this is the case if and only if both $Q_{2} x_{2} \cdots Q_{n} x_{n} S^{c}\left(1, x_{2}, \ldots, x_{n}, 1,0\right)$ and $Q_{2} x_{2} \cdots Q_{n} x_{n} S^{c}\left(0, x_{2}, \ldots, x_{n}, 1,0\right)$ are true, which holds if and only if $\forall x_{1} \cdots Q_{n} x_{n} S^{c}\left(x_{1}, \ldots, x_{n}, 1,0\right)$ is true. The proof for $Q_{1}=\exists$ is similar.
$\mathcal{C}$ is $\mathbf{0}$-valid and complementive If $\mathcal{C}$ is complementive, $C^{c}=C$ for all $C \in$ $\mathcal{C}$. The following corollary follows immediately from Lemma 18

From CKS01, Lemma 5.41], we know that $\mathcal{C}$ perfectly implements the constraint $\mathrm{SymOR}_{1}$, which is defined as the constraint $\lambda x y z .(\bar{x} \wedge(\bar{y} \vee z)) \vee(x \wedge$ $(\bar{z} \vee y)$ ).
Using Corollary [19 we can now construct a reduction that is similar to the one described at the end of the case that $\mathcal{C}$ is 0 -valid and not complementive to reduce $\operatorname{QSAT}_{i, c}(\mathcal{C})$ to $\operatorname{QSAT}_{i}(\mathcal{C})$.
Let $Q_{1} X_{1} \cdots \exists X_{i} S\left(X_{1}, \ldots, X_{i}, 0,1\right)$ be a $\Sigma_{i}(\mathcal{C})$ expression with constants if $i$ is odd, and a $\Pi_{i}(\mathcal{C})$ expression with constants if $i$ is even. We claim that this expression is true if and only if the following expression is true:

$$
\begin{aligned}
& Q_{1} X_{1} \cdots \forall X_{i-1} \forall x \forall y \forall z \exists f \exists t \exists X_{i} \\
& \quad\left[S\left(X_{1}, \ldots, X_{i}, f, t\right) \cup\left\{\operatorname{SymOR}_{1}(x, f, y), \operatorname{SymOR}_{1}(x, z, t)\right\}\right]
\end{aligned}
$$

For the proof, note that

$$
\begin{aligned}
& Q_{1} X_{1} \cdots \forall X_{i-1} \forall x \forall y \forall z \exists f \exists t \exists X_{i} \\
& \\
& {\left[S\left(X_{1}, \ldots, X_{i}, f, t\right) \cup\left\{\operatorname{SymOR}_{1}(x, f, y), \operatorname{SymOR}_{1}(x, z, t)\right\}\right]}
\end{aligned}
$$

if and only if $Q_{1} X_{1} \cdots \forall X_{i-1} \forall y \forall z \exists f \exists t \exists X_{i}\left[S\left(X_{1}, \ldots, X_{i}, f, t\right) \cup\{\bar{f} \vee y, \bar{z} \vee t\}\right]$ and $Q_{1} X_{1} \cdots \forall X_{i-1} \forall y \forall z \exists f \exists t \exists X_{i}\left[S\left(X_{1}, \ldots, X_{i}, f, t\right) \cup\{\bar{y} \vee f, \bar{t} \vee z\}\right]$.
As in the 0 -valid and not complementive case, this holds if and only if

$$
\begin{aligned}
& Q_{1} X_{1} \cdots \forall X_{i-1} \exists f \exists t \exists X_{i} {\left[S\left(X_{1}, \ldots, X_{i}, f, t\right) \cup\{\bar{f}, t\}\right] \text { and } } \\
& Q_{1} X_{1} \cdots \forall X_{i-1} \exists f \exists t \exists X_{i} {\left[S\left(X_{1}, \ldots, X_{i}, f, t\right) \cup\{\bar{t}, f\}\right] } \\
& \text { iff }
\end{aligned}
$$

$\mathcal{C}$ is not 0 -valid, not 1 -valid, and complementive In this case, $\mathcal{C}$ can perfectly implement $\lambda x y . x \oplus y$ CKS01 proof of Lemma 5.24].
Using Corollary 19, it suffices to replace 0 by $f, 1$ by $t$ and to add $\exists f \exists t\{f \oplus t\}$. However, this existential quantification has to be added at the start of the expression. For example, consider the (false) expression $\forall x\{x=0\}$. Adding the existential quantification at the end of the quantifier string will give $\forall x \exists f \exists t\{x=f, f \oplus t\}$, which is true. (It doesn't matter whether $t$ is set to 0 and $f$ to 1 or vice-versa (by complementivity). However, we need to always look at the same assignment.) Adding the existential quantifiers at the start
of the expression gives a reduction from $\operatorname{QSAT}_{i, c}(\mathcal{C})$ to $\operatorname{QSAT}_{i}(\mathcal{C})$ for $i$ odd. More formally, if $i$ is odd, we map

$$
\exists X_{1} \forall X_{2} \cdots \exists X_{i} S\left(X_{1}, \ldots, X_{i}, 0,1\right)
$$

to

$$
\exists f \exists t \exists X_{1} \forall X_{2} \cdots \exists X_{i}\left[S\left(X_{1}, \ldots, X_{i}, f, t\right) \cup\{f \oplus t\}\right]
$$

Note that this reduction also works for $i=1$.
We will now show how to reduce $\operatorname{QSAT}_{i, c}(\mathcal{C})$ to $\operatorname{QSAT}_{i}(\mathcal{C})$ for $i$ even. Let $S\left(X_{1}, \ldots, X_{i}, 0,1\right)$ be a set of constraint applications of $\mathcal{C}$ with constants. We map

$$
\forall X_{1} \exists X_{2} \cdots \exists X_{i} S\left(X_{1}, \ldots, X_{i}, 0,1\right)
$$

to

$$
\forall b \forall X_{1} \exists X_{2} \cdots \exists X_{i} \exists b^{\prime}\left[S\left(X_{1}, \ldots, X_{i}, b, b^{\prime}\right) \cup\left\{\left(b \oplus b^{\prime}\right)\right\}\right]
$$

That this is indeed a reduction follows immediately from Corollary 19
$\mathcal{C}$ is not 0 -valid, not $\mathbf{1}$-valid, and not complementive Let $A \in \mathcal{C}$ be not 0 -valid, $B \in \mathcal{C}$ be not 1 -valid, and $C \in \mathcal{C}$ be not complementive. Recall that we may assume that all constraints in $\mathcal{C}$ are satisfiable. Let $s_{A}$ be a satisfying assignment for $A$, let $s_{B}$ be a satisfying assignment for $B$, and let $s_{C}$ be a satisfying assignment for $C$ such that $\overline{s_{C}}$ is not a satisfying assignment for $C$. Let $\widehat{A}(x, y)$ be a constraint application of $A$ defined as follows: $\widehat{A}(x, y)=A\left(z_{1}, \ldots, z_{k}\right)$, where $z_{i}=x$ if $\left(s_{A}\right)_{i}=0$, and $z_{i}=y$ if $\left(s_{A}\right)_{i}=1$. Define $\widehat{B}(x, y)$ from $B$ and $s_{B}$ and $\widehat{C}(x, y)$ from $C$ and $s_{C}$ in the same way. Then $\widehat{A}(0,0)=0, \widehat{A}(0,1)=1, \widehat{B}(0,1)=1, \widehat{B}(1,1)=0$, $\widehat{C}(0,1)=1$, and $\widehat{C}(1,0)=0$. Now consider the set of constraint applications $\{\widehat{A}(f, t), \widehat{B}(f, t), \widehat{C}(f, t)\}$. It is easy to see that this set perfectly implements $\bar{f} \wedge t$.
For our reductions, we need to replace 0 by $f, 1$ by $t$, and add $\exists f \exists t\{\bar{f} \wedge t\}$. Note that, unlike the previous case, we can add the existential quantifiers anywhere in the quantifier string, since $\exists f \exists t\{\bar{f} \wedge t\}$ completely fixes the truth assignment to $f$ and $t$.
More formally, to reduce $\operatorname{QSAT}_{i, c}(\mathcal{C})$ to $\operatorname{QSAT}_{i}(\mathcal{C})$, map $Q_{1} X_{1} Q_{2} X_{2} \cdots \forall Q_{i-1} \exists X_{i} S\left(X_{1}, \ldots, X_{i}, 0,1\right)$ to $Q_{1} X_{1} Q_{2} X_{2} \cdots \forall Q_{i-1} \exists X_{i} \exists f \exists t\left[S\left(X_{1}, \ldots, X_{i}, f, t\right) \cup\{\bar{f} \wedge t\}\right]$. This shows that $\operatorname{QSAT}_{i}^{p}(\mathcal{C})$ is $\Sigma_{i}^{p}$-hard.
As in the previous case, this reduction will work for $i=1$ as well. Thus, our proofs also imply Schaefer's dichotomy theorem.
