

# Capacity of Differential versus Non-Differential Unitary Space-Time Modulation for MIMO channels

Aris L. Moustakas, *Senior Member, IEEE*, Steven H. Simon and Thomas L. Marzetta, *Fellow, IEEE*

**Abstract**—Differential Unitary Space-Time Modulation (DUSTM) and its earlier nondifferential counterpart, USTM, permit high-throughput MIMO communication entirely without the possession of channel state information (CSI) by either the transmitter or the receiver. For an isotropically random unitary input we obtain the exact closed-form expression for the probability density of the DUSTM received signal, which permits the straightforward Monte Carlo evaluation of its mutual information. We compare the performance of DUSTM and USTM through both numerical computations of mutual information and through the analysis of low- and high-SNR asymptotic expressions. In our comparisons the symbol durations of the equivalent unitary space-time signals are both equal to  $T$ , as are the number of receive antennas  $N$ . For DUSTM the number of transmit antennas is constrained by the scheme to be  $M = T=2$ , while USTM has no such constraint. If DUSTM and USTM utilize the same number of transmit antennas at high SNR's the normalized mutual information of the differential and the nondifferential schemes expressed in bits/sec/Hz are asymptotically equal, with the differential scheme performing somewhat better, while at low SNR's the normalized mutual information of DUSTM is asymptotically twice the normalized mutual information of USTM. If, instead, USTM utilizes the optimum number of transmit antennas then USTM can outperform DUSTM at sufficiently low SNR's.

**Index Terms**—Non-coherent Communication, Capacity, Space-Time Coding, Multiple Antennas, Differential Encoding, Multiplicative Channels.

## I. INTRODUCTION

CONSIDERABLE volume of work has followed the prediction [1], [2] that the use of multiple antennas in transmitting and receiving signals can result to substantial increases in information throughput. The underlying assumptions of this effort have been that the receiver knows the channel through some training scheme and that the channel coefficients are statistically independent. In this case and for large signal to noise ratio, the capacity is roughly

$$C_{\text{coh}} = \min(M, N) \log_2 \text{ bits/sec/Hz} \quad (1)$$

where  $M$ ,  $N$  are the numbers of transmitting and receiving antennas.

In a typical mobile wireless communication system the channel coefficients vary continuously, following a Jakes-like distribution. Thus one can only assume that the channel is approximately constant over only limited periods of time.

A. L. Moustakas (email: arislm@phys.uoa.gr), S. H. Simon (email: shsimon@bell-labs.com) and T. L. Marzetta (email: tlm@research.bell-labs.com) are with Lucent Technologies.

Hence, especially for large transmitting antenna numbers, training will require a substantial fraction of the coherence time of the channel and thus hamper the data throughput rates. To address this problem, Marzetta and Hochwald [3], [4] investigated the scenario where the receiver has no a-priori channel knowledge. In addition to the conventional additive Gaussian noise, this channel has also multiplicative noise, corresponding to the channel matrix, which is also assumed to be Gaussian. This is a “non-coherent” channel, as opposed to the additive white Gaussian noise channel with known (and static) “coherent” channel coefficients at the receiver. In an elegant group-theoretic approach, Zheng and Tse [5] found the capacity of this channel to scale as

$$C_{\text{incoh}} = \min(M, T) \log_2 \text{ bits/sec/Hz} \quad (2)$$

for large  $M$ , where  $M = \min(M, N; T=2)$  and  $T$  is the number of time intervals over which the channel is static. A similar approach was developed independently by [6]. This implies that for fixed  $T$ , there is no need to use more than  $M = T=2$  transmitters.

To take advantage of the constancy of the channel over  $T$  time intervals, [4] proposed to encode the signal using  $T \times M$  isotropic unitary matrices. In this encoding, called isotropic unitary space-time modulation (USTM), a symbol can be spread not only over  $M$  antennas, but also over  $T$  time intervals. Some analytic results on the mutual information of USTM already exist. In particular, it has been shown that for  $T = M$  [3] and for  $M < \min(N; T=2)$  and large  $M$  [5] the optimal input distribution is isotropic random unitary, i.e. that of USTM. Thus the asymptotic capacity is equal to the mutual information, as in [2], [3], [5]. Recently, Hassibi and Marzetta [7] analytically calculated the received signal distribution and thus were able to numerically evaluate the mutual information of USTM for a variety of  $M$ ,  $T$ ,  $N$  and  $\rho$ , confirming some of the above asymptotic results. More recently, [8] generalized the received signal distribution to channels with spatial correlation.

In the case of USTM it is implicitly assumed that, after  $T$  symbols the channel completely changes. In contrast, differential phase-shift keying (DPSK) [9] has been used extensively to take advantage of the continuous slow-varying nature of the channel, without needing to perform any training. In this scheme, each transmitted symbol is encoded into a phase-difference from the previous symbol.

In [10], [11], the concept of differential modulation was extended to multi-antenna systems. In this method, called

differential unitary space-time modulation (DUSTM), the signal is encoded over  $M$  transmitting antennas and  $M$  time intervals using an  $M \times M$  unitary matrix. In each successive  $M$  time intervals, the transmitter encodes the input signal by multiplying a  $M \times M$  unitary matrix to the unitary matrix transmitted during the previous  $M$  time intervals over the  $M$  antennas and then transmits the matrix product. In turn, the receiver decodes the signal by comparing the received signal from the  $M$  antennas and  $M$  time intervals to that received over the previous  $M$  time intervals. Thus this scheme requires no training and assumes that the channel is fixed over  $T = 2M$  time intervals. The technique of DUSTM can be applied to the mathematically identical space-frequency channel that appears during a single OFDM symbol interval, resulting in a variation called differential unitary space-frequency modulation (DUSFM) [12].

Despite its importance in practical applications [10], no analytic results are available regarding the mutual information of DUSTM and its comparison with USTM for  $T = 2M$ . The main obstacle has been the difficulty in integrating over exponentials of unitary matrices. This is a problem that was tackled in the 80's by high-energy physicists in analyzing the nuclear strong interactions (quantum chromodynamics). Due to the  $SU(3)$  symmetry of these interactions their fluctuations can in certain cases be represented by unitary matrices. Thus to integrate them out, one needs to make use of such integrals of exponentials of unitary matrices. In this paper we apply these results derived by [13] to the context of DUSTM. The methodology of the proof in [13] is based on mapping the original problem to a diffusion problem of eigenvalues, which has a differential equation that can be solved. Given its complexity it will not be discussed at all in this paper. However, the interested reader is referred to [8], where some of us apply the method of character expansion to derive the same result and apply it to the capacity of Ricean MIMO channels. In the present paper, we get the following results:

- 1) We analytically calculate the received signal distribution for the case of DUSTM (see section III).
- 2) Using this received signal distribution, we evaluate numerically  $I_{DUSTM}$ , the mutual information of DUSTM for a variety of  $M$ ,  $N$  and  $T$ , and compare it to  $I_{USTM}$ , the mutual information of USTM setting  $T = 2M$ . At low  $T$  we find that the two mutual informations for the same  $M$ ,  $N$ ,  $T = 2M$  are nearly identical. This implies that the number of bits *per symbol* i.e.  $I_{DUSTM} = M$  is twice  $I_{USTM} = T = I_{USTM} = 2M$ . In contrast, at large  $T$  the number of bits/symbol of the two schemes approach each other, but with  $I_{DUSTM} = M > I_{USTM} = T$ .
- 3) We compare the maximum with respect to  $M$  of the two mutual informations per symbol. For fixed  $M$ ,  $N$ ,  $T = 2M$ , we find that while at large  $T$  we have  $\max_M I_{DUSTM}(M; N; T) = M > \max_M I_{USTM}(M; N; T) = T$ , at small  $T$  the opposite inequality holds.
- 4) We back the above numerical results by providing expansions of the mutual information for both small and large  $T$ .

## II. DEFINITIONS

### A. Notation

Throughout this paper we will denote the number of time-intervals, transmitting antennas and receiving antennas with  $T$ ,  $M$ ,  $N$ , respectively.  $R$ ,  $K$  and  $Q$  will represent  $R = \min(M; N)$ ,  $K = \min(T; N)$  and  $Q = \max(M; N) = \min(M; N)$ .

In addition, we will use bold-faced upper-case letters to represent matrices, e.g.  $X$ , with elements given by  $X_{ij}$ , bold-faced lower-case letters for column vectors, e.g.  $x$ , with elements  $x_i$ , and non-bold lower-case letters for scalar quantities.  $\text{Tr } X$  will represent the trace of  $X$ , while the superscripts  $T$  and  $y$  will indicate transpose and Hermitian conjugate operations. The determinant of a matrix will be represented by  $\det(X)$  or by  $\det(X_{ij})$ . Also,  $I_n$  will denote the  $n$ -dimensional identity matrix, while  $J_n$  will represent a  $T \times T$  matrix with zeros in all elements other than the first  $n$  diagonals, which have unit value.

The complex, circularly symmetric Gaussian distribution with zero-mean and unit-variance will be denoted by  $CN(0; 1)$ .

The per-symbol normalized mutual information will be given by  $\hat{I}$ , measured in bits/sec/Hz. Thus for the case of USTM,  $\hat{I}_{USTM} = I_{USTM}/T$ , while for DUSTM,  $\hat{I}_{DUSTM} = I_{DUSTM}/M$ .

### B. System Model

We consider the case of single-user transmission from  $M$  transmit antennas to  $N$  receive antennas over a narrow-band block-fading channel. The channel coefficients are assumed to be constant over time intervals of length  $T$ , after which they acquire independent values, which in turn remain constant for the same time interval. The received  $T \times N$ -dimensional complex signal  $X$  can be written in terms of the  $T \times M$ -dimensional transmitted complex signal  $s$  as

$$X = \frac{\sqrt{P}}{M} H + W \quad (3)$$

where  $H$  is a  $M \times N$  matrix with the channel coefficients from the transmitting to the receiving arrays and  $W$  is the  $T \times N$  additive noise matrix. Both  $H$  and  $W$  are assumed to have elements that are independent and  $CN(0; 1)$ -distributed. Their instantaneous values are assumed to be unknown to both the transmitter and the receiver. The first term in (3) is normalized, so that  $P$  is the total average signal-to-noise ratio (SNR) transmitted from all antennas.

### C. Unitary Matrices for Isotropic and Differential USTM

In this paper we will be dealing with unitary input distributions. For the case of USTM  $s$  is a member of the  $S(M; T)$  Stiefel manifold (see [14]) i.e. the set of all complex  $T \times M$  matrices, such that

$$s^H s = I_M \quad (4)$$

Note that it is implicitly assumed here that  $T \geq M$ , since only thus can  $M \times T$ -dimensional vectors be mutually orthogonal.

It is convenient here to introduce  $\mathbf{Q}$ , the  $T \times (T - M)$  orthogonal complement of  $\mathbf{U}$ , i.e. with

$$\mathbf{U}^T + \mathbf{Q}^T \mathbf{Q}^T = \mathbf{I}_T \quad \text{and} \quad \mathbf{Q}^T \mathbf{Q}^T = \mathbf{I}_{T-M} \quad (5)$$

so that  $\mathbf{V} = [\mathbf{U}^T \mathbf{Q}^T]^T$  is a  $T \times T$  unitary matrix with  $\mathbf{V}^T = \mathbf{I}_T$ .

For the case of DUSTM, we restrict ourselves to the  $U(M, 2M)$  subgroup of the  $S(M, 2M)$  Stiefel manifold, such that [10]

$$\mathbf{V} = \frac{1}{\sqrt{2}} \begin{bmatrix} \mathbf{I}_M \\ \mathbf{U} \end{bmatrix} \quad (6)$$

where  $\mathbf{U}$  is an  $M \times M$  unitary matrix.

#### D. Mutual Information

For fixed  $\mathbf{X}$ ,  $\mathbf{Y}$  in (3) is a sum of two Gaussian matrices, therefore its probability density conditional on  $\mathbf{X}$  can be written as

$$p(\mathbf{Y} | \mathbf{X}) = \frac{\exp \left\{ -\frac{1}{2} \text{Tr} \left( \mathbf{X}^T \mathbf{Y} \mathbf{I}_T + \frac{T}{M} \mathbf{Y}^T \mathbf{Y} \right) \right\}}{2^{TN} \det(\mathbf{I}_T + \frac{T}{M} \mathbf{Y} \mathbf{Y}^T)} \quad (7)$$

To evaluate the inverse of the matrix in the exponent we use (4), 5 to get the expression  $\mathbf{Y} = \mathbf{J}_M \mathbf{Y}$ . Applying this we get

$$\begin{aligned} \mathbf{I}_T + \frac{T}{M} \mathbf{Y}^T \mathbf{Y} &= \mathbf{I}_T + \frac{T}{M} \mathbf{J}_M^T \mathbf{Y}^T \mathbf{Y} \mathbf{J}_M \\ &= \mathbf{I}_T + \frac{T}{M} \mathbf{J}_M^T \mathbf{J}_M \mathbf{Y}^T \mathbf{Y} \\ &= \mathbf{I}_T + \frac{T}{M} \mathbf{Y}^T \mathbf{Y} + \frac{M}{M+T} \mathbf{Y}^T \mathbf{Y} \\ &= \mathbf{I}_T + \frac{T}{M+T} \mathbf{Y}^T \mathbf{Y} \end{aligned} \quad (8)$$

We can therefore express  $p(\mathbf{Y} | \mathbf{X})$  as

$$p(\mathbf{Y} | \mathbf{X}) = \frac{\exp \left\{ -\frac{1}{2} \text{Tr} \left( \mathbf{X}^T \mathbf{Y} \mathbf{I}_T + \frac{T}{M+T} \mathbf{Y}^T \mathbf{Y} \right) \right\}}{2^{TN} (1 + \frac{T}{M})^{MN}} \quad (9)$$

The mutual information between  $\mathbf{X}$  and  $\mathbf{Y}$  is given by

$$I(\mathbf{X}; \mathbf{Y}) = \int \int p(\mathbf{X}) p(\mathbf{Y} | \mathbf{X}) \log_2 \frac{p(\mathbf{Y} | \mathbf{X})}{p(\mathbf{Y})} d\mathbf{X} d\mathbf{Y} \quad (10)$$

$p(\mathbf{X})$  is the received signal probability density given by

$$p(\mathbf{X}) = \int p(\mathbf{Y} | \mathbf{X}) p(\mathbf{Y}) d\mathbf{Y} \quad (11)$$

where we introduced the notation  $\int$  as the integration over  $\mathbf{Y}$ .

The integration over  $\mathbf{Y}$  in (10) can be eliminated by noting [7] first that

$$p(\mathbf{Y} | \mathbf{X}) = p(\mathbf{Y}^T \mathbf{X} \mathbf{Y} | \mathbf{X}) \quad (12)$$

The choice of  $\mathbf{Y}$  depends on the particular application. Thus, for the case of USTM the following expression can be used

$$\mathbf{Y} = \begin{bmatrix} \mathbf{I}_M \\ \mathbf{0}_{T-M} \end{bmatrix} \quad (13)$$

$$\mathbf{Y} = \frac{1}{\sqrt{2}} \begin{bmatrix} \mathbf{I}_M \\ \mathbf{I}_M \end{bmatrix} \quad (14)$$

which is the identity matrix of matrices of the form of (6). Using (12) and through the change of variables  $\mathbf{X} \rightarrow \mathbf{Y}^T \mathbf{X} \mathbf{Y}$ , which leaves the  $\mathbf{X}$ -integration measure unaffected, we completely eliminate any non-trivial  $\mathbf{Y}$ -dependence of the integrand of (10). The remaining  $\int p(\mathbf{Y}) d\mathbf{Y}$  can be easily integrated to give unity and thus is disregarded. This results to

$$I(\mathbf{X}; \mathbf{Y}) = \int d\mathbf{X} p(\mathbf{X} | \mathbf{Y}) \log_2 \frac{p(\mathbf{X} | \mathbf{Y})}{p(\mathbf{X})} \quad (15)$$

#### III. CLOSED-FORM SOLUTION OF $p(\mathbf{X} | \mathbf{Y})$ FOR DUSTM

When dealing with DUSTM, it is convenient to express the conditional probability in terms of  $\mathbf{U}$ , defined in (6). Thus, if we express  $\mathbf{X}$  as

$$\mathbf{X} = [\mathbf{X}_1 \mathbf{X}_2]^T \quad (16)$$

where both  $\mathbf{X}_1$  and  $\mathbf{X}_2$  have dimensions  $M \times N$ , then (9) can be rewritten in terms of  $\mathbf{X}_1$ ,  $\mathbf{X}_2$  and  $\mathbf{U}$  as

$$p(\mathbf{X} | \mathbf{Y}) = \frac{\exp \left\{ -\frac{1}{2} \text{Tr} \left( \mathbf{X}_1^T \mathbf{X}_1 + \mathbf{X}_2^T \mathbf{X}_2 \right) \right\}}{2^{2MN} (1 + 2)^{MN}} \exp \left\{ -\frac{1}{2} \text{Tr} \left( \mathbf{X}_2 \mathbf{X}_1^T \mathbf{U} + \mathbf{X}_1 \mathbf{X}_2^T \mathbf{U}^T \right) \right\} \quad (17)$$

Combining this with (11) we get

$$p(\mathbf{X}) = \frac{\exp \left\{ -\frac{1}{2} \text{Tr} \left( \mathbf{X}_1^T \mathbf{X}_1 + \mathbf{X}_2^T \mathbf{X}_2 \right) \right\}}{2^{2MN} (1 + 2)^{MN}} \exp \left\{ -\frac{1}{2} \text{Tr} \left( \mathbf{X}_2 \mathbf{X}_1^T \mathbf{U} + \mathbf{X}_1 \mathbf{X}_2^T \mathbf{U}^T \right) \right\} \quad (18)$$

where

$$\mathbf{U} = \frac{1}{1 + 2} \quad (19)$$

We can now use the result of [13] to get

$$\exp \left\{ -\frac{1}{2} \text{Tr} \left( \mathbf{X}_2 \mathbf{X}_1^T \mathbf{U} + \mathbf{X}_1 \mathbf{X}_2^T \mathbf{U}^T \right) \right\} = \prod_{k=0}^{M-1} \frac{\det \left( \mathbf{Y}_j^{(i-1)=2} \mathbf{I}_{i-1} (2\mathbf{Y}_j^{1=2}) \right)}{\det \mathbf{Y}_j^{i-1}} \quad (20)$$

where  $\mathbf{Y}_j$  for  $j = 1 :: M$  are the eigenvalues of  $\mathbf{X}_2 \mathbf{X}_1^T \mathbf{X}_1 \mathbf{X}_2^T$  (or the squares of the svd's of  $\mathbf{X}_2 \mathbf{X}_1^T$ ). This equation is essentially the generating functional of  $\mathbf{U}$ : Any moment of  $\mathbf{U}$  can be evaluated by taking arbitrary derivatives with respect of elements of the matrix  $\mathbf{X}_2 \mathbf{X}_1^T$  on both sides of (20) and subsequently setting this matrix to zero.

The determinant in the denominator is the Vandermonde determinant

$$\begin{aligned} (\det \mathbf{Y}_j^{i-1}) &= \det \begin{bmatrix} \mathbf{Y}_1^{i-1} & \mathbf{Y}_2^{i-1} & \dots & \mathbf{Y}_M^{i-1} \end{bmatrix} \\ &= \begin{bmatrix} \mathbf{Y}_1^{i-1} & \mathbf{Y}_2^{i-1} & \dots & \mathbf{Y}_M^{i-1} \end{bmatrix} \begin{bmatrix} 1 & 1 & \dots & 1 \\ \mathbf{Y}_1 & \mathbf{Y}_2 & \dots & \mathbf{Y}_M \\ \mathbf{Y}_1^2 & \mathbf{Y}_2^2 & \dots & \mathbf{Y}_M^2 \\ \vdots & \vdots & \ddots & \vdots \\ \mathbf{Y}_1^{M-1} & \mathbf{Y}_2^{M-1} & \dots & \mathbf{Y}_M^{M-1} \end{bmatrix} \end{aligned} \quad (21)$$

while the determinant in the numerator can be written explicitly as

$$\det \mathbf{Y}_j^{(i-1)=2} \mathbf{I}_{i-1} (2\mathbf{Y}_j^{1=2}) = \begin{pmatrix} \mathbf{I}_0 (2\mathbf{Y}_1^{1=2}) \\ \mathbf{Y}_1^{1=2} \mathbf{I}_1 (2\mathbf{Y}_1^{1=2}) \\ \mathbf{Y}_1 \mathbf{I}_2 (2\mathbf{Y}_1^{1=2}) \\ \vdots \\ \mathbf{Y}_1^{(M-1)=2} \mathbf{I}_{M-1} (2\mathbf{Y}_1^{1=2}) \end{pmatrix} \begin{pmatrix} \mathbf{I}_0 (2\mathbf{Y}_M^{1=2}) \\ \mathbf{Y}_M^{1=2} \mathbf{I}_1 (2\mathbf{Y}_M^{1=2}) \\ \mathbf{Y}_M \mathbf{I}_2 (2\mathbf{Y}_M^{1=2}) \\ \vdots \\ \mathbf{Y}_M^{(M-1)=2} \mathbf{I}_{M-1} (2\mathbf{Y}_M^{1=2}) \end{pmatrix} \quad (22)$$

where  $\mathbf{I}_n(x)$  is the modified Bessel function of order  $n$ .

One has to exercise caution in evaluating (20) in the case  $M < N$ . The reason is that only  $R$  singular values of  $\mathbf{X}_1 \mathbf{X}_2^H$  are non-zero. Therefore, both the determinants in the numerator and the denominator vanish. However, the ratio remains finite. Using Lemma 1 in Appendix I we can show that

$$\exp \left( \text{Tr} \mathbf{X}_2 \mathbf{X}_1^H \mathbf{U} + \mathbf{X}_1 \mathbf{X}_2^H \mathbf{U}^H \right) = \frac{\det \mathbf{Y}_j^{(M-R+i-1)=2} \mathbf{I}_{M-R+i-1} (2\mathbf{Y}_j^{1=2})}{k! \det \mathbf{Y}_j^{(M-R+i-1)=2} \mathbf{I}_{M-R+i-1} (2\mathbf{Y}_j^{1=2})} \quad (23)$$

where the range of the indices in the determinants are  $i; j = 1; \dots; R$ .

#### IV. MUTUAL INFORMATION OF DUSTM

Using (17), (18) and (23) we can now express the ratio  $p(\mathbf{X}; j_0) = p(\mathbf{X})$  as

$$\log_2 \frac{p(\mathbf{X}; j_0)}{p(\mathbf{X})} = \log_2 \frac{\prod_{k=M-R}^M \frac{1}{k!} \det \mathbf{Y}_j^{(M-R+i-1)=2} \mathbf{I}_{M-R+i-1} (2\mathbf{Y}_j^{1=2})}{\det \mathbf{Y}_j^{(M-R+i-1)=2} \mathbf{I}_{M-R+i-1} (2\mathbf{Y}_j^{1=2})} + \sum_{i=1}^R \text{Tr} \mathbf{X}_1^H \mathbf{X}_2 + \mathbf{X}_2^H \mathbf{X}_1 \log_2 e \quad (24)$$

In the above equation we have defined  $\mathbf{I}_n(x) = \mathbf{I}_n(x) e^{-x}$  and we have multiplied both numerator and denominator of the expression inside the log with  $\exp \left( \sum_{i=1}^R \text{Tr} \mathbf{X}_1^H \mathbf{X}_2 + \mathbf{X}_2^H \mathbf{X}_1 \right)$ , so that neither will have exponentially increasing terms for large  $\mathbf{Y}_i$ .

To evaluate the mutual information, (24) needs to be averaged over realizations of  $\mathbf{X}_1, \mathbf{X}_2$ , which are generated with probability distribution  $p(\mathbf{X}; j_0)$ . This corresponds to  $\mathbf{X}_1, \mathbf{X}_2$  having Gaussian correlations given by

$$\mathbb{E}[\mathbf{X}_{1i} \mathbf{X}_{1j}] = (1 + \delta_{ij}) \quad (25)$$

$$\mathbb{E}[\mathbf{X}_{2i} \mathbf{X}_{2j}] = (1 + \delta_{ij}) \quad (26)$$

$$\mathbb{E}[\mathbf{X}_{1i} \mathbf{X}_{2j}] = \delta_{ij} \quad (27)$$

#### V. MUTUAL INFORMATION OF USTM

In the next section we will compare the mutual information of DUSTM to that of USTM. Thus, for completeness, we

review here the results obtained in [7] regarding USTM. We start with the conditional probability  $p(\mathbf{X}; j)$

$$p(\mathbf{X}; j) = \frac{\exp \left( \text{Tr} \mathbf{X}^H \mathbf{X} \right) \exp \left( \text{Tr} \mathbf{X}^H \mathbf{Y} \mathbf{Y}^H \mathbf{X} \right)}{\mathbf{T}^N (1 + \mathbf{T}^M)^{M \cdot N}} \quad (28)$$

where  $\mathbf{X}$  is a  $T \times N$  complex matrix,  $\mathbf{Y}$  is a  $T \times N$  unitary matrix and

$$\mathbf{T} = \frac{\mathbf{T}}{M + \mathbf{T}} \quad (29)$$

In [7] the received signal probability density was found to be

$$p(\mathbf{X}) = \int \mathbf{Z} p(\mathbf{X}; j) \quad (30)$$

$$= \frac{\exp \left( \text{Tr} \mathbf{X}^H \mathbf{X} \right)}{\mathbf{T}^N (1 + \mathbf{T}^M)^{M \cdot N}} \int \exp \left( \text{Tr} \mathbf{X}^H \mathbf{Y} \mathbf{Y}^H \mathbf{X} \right) \mathbf{Z}$$

where the average over  $\mathbf{Z}$ , expressed as  $\mathbf{h}$ , was performed as follows:

$$\begin{aligned} & \exp \left( \text{Tr} \mathbf{X}^H \mathbf{Y} \mathbf{Y}^H \mathbf{X} \right) \mathbf{Z} \\ &= \frac{C_{TM}}{M!} \frac{dt_1}{2} \frac{dt_M}{2} \int \frac{e^{-it_m}}{\left( \mathbf{Y}_1 \mathbf{I}_m \right) \left( \mathbf{Y}_M \mathbf{I}_m \right) \left( \mathbf{I}_m \right)^{T \cdot K}} \\ & \quad \left( \mathbf{I}_m \mathbf{I}_m \right)^2 \\ & \quad \int \mathbf{Z} \mathbf{Z}^H \\ &= C_{TM} \det \mathbf{F} \end{aligned} \quad (31)$$

where the constant  $C_{TM}$  is equal to

$$C_{TM} = \frac{(T-1)!}{(M-1)!} \frac{(T-M)!}{(0)!} \quad (32)$$

and  $\mathbf{F}$  is a  $M \times M$  Hankel matrix with entries given by

$$F_{mn} = \sum_{k=1}^K \frac{e^{-Y_k}}{\left( Y_k \right)^q \Gamma(q)} \quad (33)$$

In the above expression,  $q = T - K - m - n + 2$ ,  $(n; x)$  is the incomplete  $\Gamma$  function and  $\mathbf{Y}_n$ , for  $n = 1; \dots; K$  are the non-zero eigenvalues of the  $N \times N$  matrix  $\mathbf{X}^H \mathbf{X}$ . As in the case of DUSTM, to numerically calculate the mutual information one needs to average the log-ratio  $\log_2 (p(\mathbf{X}; j_0) / p(\mathbf{X}))$ , where  $p(\mathbf{X}; j_0)$  is given by (13), with respect to  $\mathbf{X}$ , which has probability density  $p(\mathbf{X}; j_0)$ . It is convenient to write  $\mathbf{X}^H \mathbf{X}$  as

$$\mathbf{X}^H \mathbf{X} = \mathbf{I} + \frac{\mathbf{T}}{M} \mathbf{X}_1^H \mathbf{X}_1 + \mathbf{X}_2^H \mathbf{X}_2 \quad (34)$$

where  $\mathbf{X}_1, \mathbf{X}_2$  are  $M \times N$ ,  $(T-M) \times N$  complex Gaussian, unit-variance matrices.

L values. For intermediate and large we have found that  $L = 4, 5, 10$  are sufficient. However, for smaller, at least  $L = 5, 10$  are required. The reason is that the mutual information, being  $O(\gamma^2)$ , is quite small and therefore fluctuations have a more pronounced effect.

In Fig. 1 we compare the numerically evaluated mutual information of USTM and DUSTM for low, intermediate and relatively large SNR values. We find that for small  $\gamma = 6$  dB the normalized mutual information  $\hat{I}_{DUSTM}$  is nearly exactly twice  $\hat{I}_{USTM}$ . This is in agreement with (35) and (36). Even for intermediate SNR,  $\gamma = 6$  dB we find the approximate relation  $\hat{I}_{USTM}(T = 2M; M; 2N) \approx \hat{I}_{DUSTM}(T = 2M; M; N)$ . This approximation breaks down for larger  $\gamma$ .

Motivated by these ratio dependencies and scaling relations, in Fig. 2 we analyze the dependence of ratios of  $\hat{I}_{DUSTM}$  and  $\hat{I}_{USTM}$  on SNR. In Fig. 2(a) we plot the ratio  $\hat{I}_{DUSTM}(T = 2M; M; N = rM) / \hat{I}_{USTM}(T = 2M; M; N = rM)$  as a function of  $\gamma$  for various values of  $M$  and for  $r = 1/2, r = 1$  and  $r = 2$ . We find that for fixed  $r$ , the ratios fall close (but not on top) to each other. Their value starts from very close to 2, for small  $\gamma$  and in accordance with (35), (36), and approaches  $2(1 - 0.5 \ln(1/r))$ , in agreement with (37), (39). We note however the slow convergence to their asymptotic values for large  $\gamma$ , which can be explained by the fact that both mutual informations increase only logarithmically with  $\gamma$ . The closeness of the curves for fixed  $r$  indicates that the ratio has weak dependence on the actual values of  $T; M; N$ . Thus a large- $T; M; N$  analysis is expected to give good results even for small antenna numbers.

In Fig. 2(b) we plot the ratios  $\hat{I}_{DUSTM}(T = 2M; M; N = rM) / \hat{I}_{DUSTM}(2; 1; N = 1)$  as a function of  $\gamma$  for various values of  $M$  and  $r$ .

In Fig. 3 we analyze the mutual information of DUSTM and USTM optimized over the number of transmitting antennas  $M$  with  $T$  fixed to  $T = 8$  and for various values of  $N$ . In Figs 3(a),(b) we plot the capacity of DUSTM and USTM defined as

$$C_{DUSTM} = \max_M \hat{I}_{DUSTM}(T = 2M; M; N) \quad (41)$$

$$= \hat{I}_{DUSTM}(T; T=2; N)$$

$$C_{USTM} = \max_M \hat{I}_{USTM}(T; M; N) \quad (42)$$

as a function of  $\gamma$  (solid curves). In Fig. 3(c) the solid curves depict the optimal number of  $M$  that maximizes  $\hat{I}_{USTM}(T; M; N)$

$$M_{opt} = \arg \max_M \hat{I}_{USTM}(T; M; N) \quad (43)$$

as a function of  $\gamma$ . As seen in (41), the optimal  $M$  for DUSTM is always equal to  $M = T=2$ , consistent with both low and large  $\gamma$  analysis. In Figs. 3(b),(c) the dashed curves represent the capacity and optimal  $M$  values as evaluated using the large- $\gamma$  asymptotic expressions of (37), (39). Very good agreement with the exact values (solid curves) can be seen down to moderate SNR. However, one should note, that even though (39) describes the capacity accurately down to moderate SNR, the large- $\gamma$  optimal value of  $M$  as predicted

by simply maximizing the  $\log$  term in (2) [5] and in (39), actually becomes optimal at very large  $\gamma = 50$  dB.

Turning now to Fig. 3(a) we see that at relatively small SNR,  $C_{USTM}$  and  $C_{DUSTM}$  actually cross each other. At high SNR, DUSTM consistently performs better than USTM. At low SNR, USTM, when optimized over  $M$  performs better than DUSTM. This can be explained by looking at the leading term of (36): the optimal  $M$  is  $M_{opt} = 1$  and  $\hat{I}_{USTM}(T; 1; N)$  can be higher than  $\hat{I}_{DUSTM}(T; T=2; N)$ . Interestingly, the analytic estimates at low SNR do not match very accurately to the behavior at  $\gamma = 6$  dB.

## VII. CONCLUSIONS

In conclusion, we have found a closed-form expression for the probability density of the received signal for differential unitary space-time modulated (DUSTM) signals. This allowed us to evaluate numerically the corresponding mutual information. In addition, we calculated analytically the asymptotic form of the mutual information for DUSTM and USTM for small and large SNR's. At low SNR's the nondifferential form of USTM can outperform the differential form if the number of transmit antennas is optimized. However, at high enough SNR's the differential USTM outperforms its nondifferential counterpart with respect to mutual information. An additional advantage of DUSTM over USTM is its simplicity of decoding, though recent progress has been reported for decoding of nondifferential USTM [17]. This suggests that DUSTM is a promising type of transmission for non-coherent MIMO channels. It would be interesting to test the competitive advantage of differential USTM in cases when  $T > 2M$ , for example when  $T$  is a higher multiple of  $2M$ . In that case the successive use of differential USTM could be assessed.

## APPENDIX I

*Lemma 1:* Let  $f_{ij}(x_i)$  represent the  $i; j$ -th element of a  $T \times T$  dimensional matrix. Here  $f_j(x)$  for  $j = 1; \dots; T$  is a family of analytic functions and  $fx_i g$  is a  $T$ -plet of real numbers. For simplicity we represent this matrix in terms of its columns denoted by  $f(x_i) = [f_1(x_i) f_2(x_i) \dots f_T(x_i)]^T$ . Also we denote by  $(fx_i g)$  the Vandermonde determinant of the  $x_j$ 's

$$(fx_i g) = \det(x_i^{(j-1)}) = \prod_{j>i} (x_j - x_i) \quad (44)$$

Thus, in the limit that a subset of  $k$  members of the  $T$ -plet are equal with each other (i.e.  $x_1 = \dots = x_k$ , for  $k < T$ ), then the ratio of  $\det f_i(x_j) = (fx_i g)$  exists and is equal to

$$\lim_{x_1 \dots x_{k-1} \rightarrow x_k} \frac{\det [f(x_1) f(x_2) \dots f(x_T)]}{\det [f(x_1) f(x_2) \dots f(x_{k-1}) f(x_k) \dots f(x_T)]} = \frac{\det [f(x_1) f(x_2) \dots f(x_T)]}{\det [f(x_1) f(x_2) \dots f(x_{k-1}) f(x_k) \dots f(x_T)]} \quad (45)$$

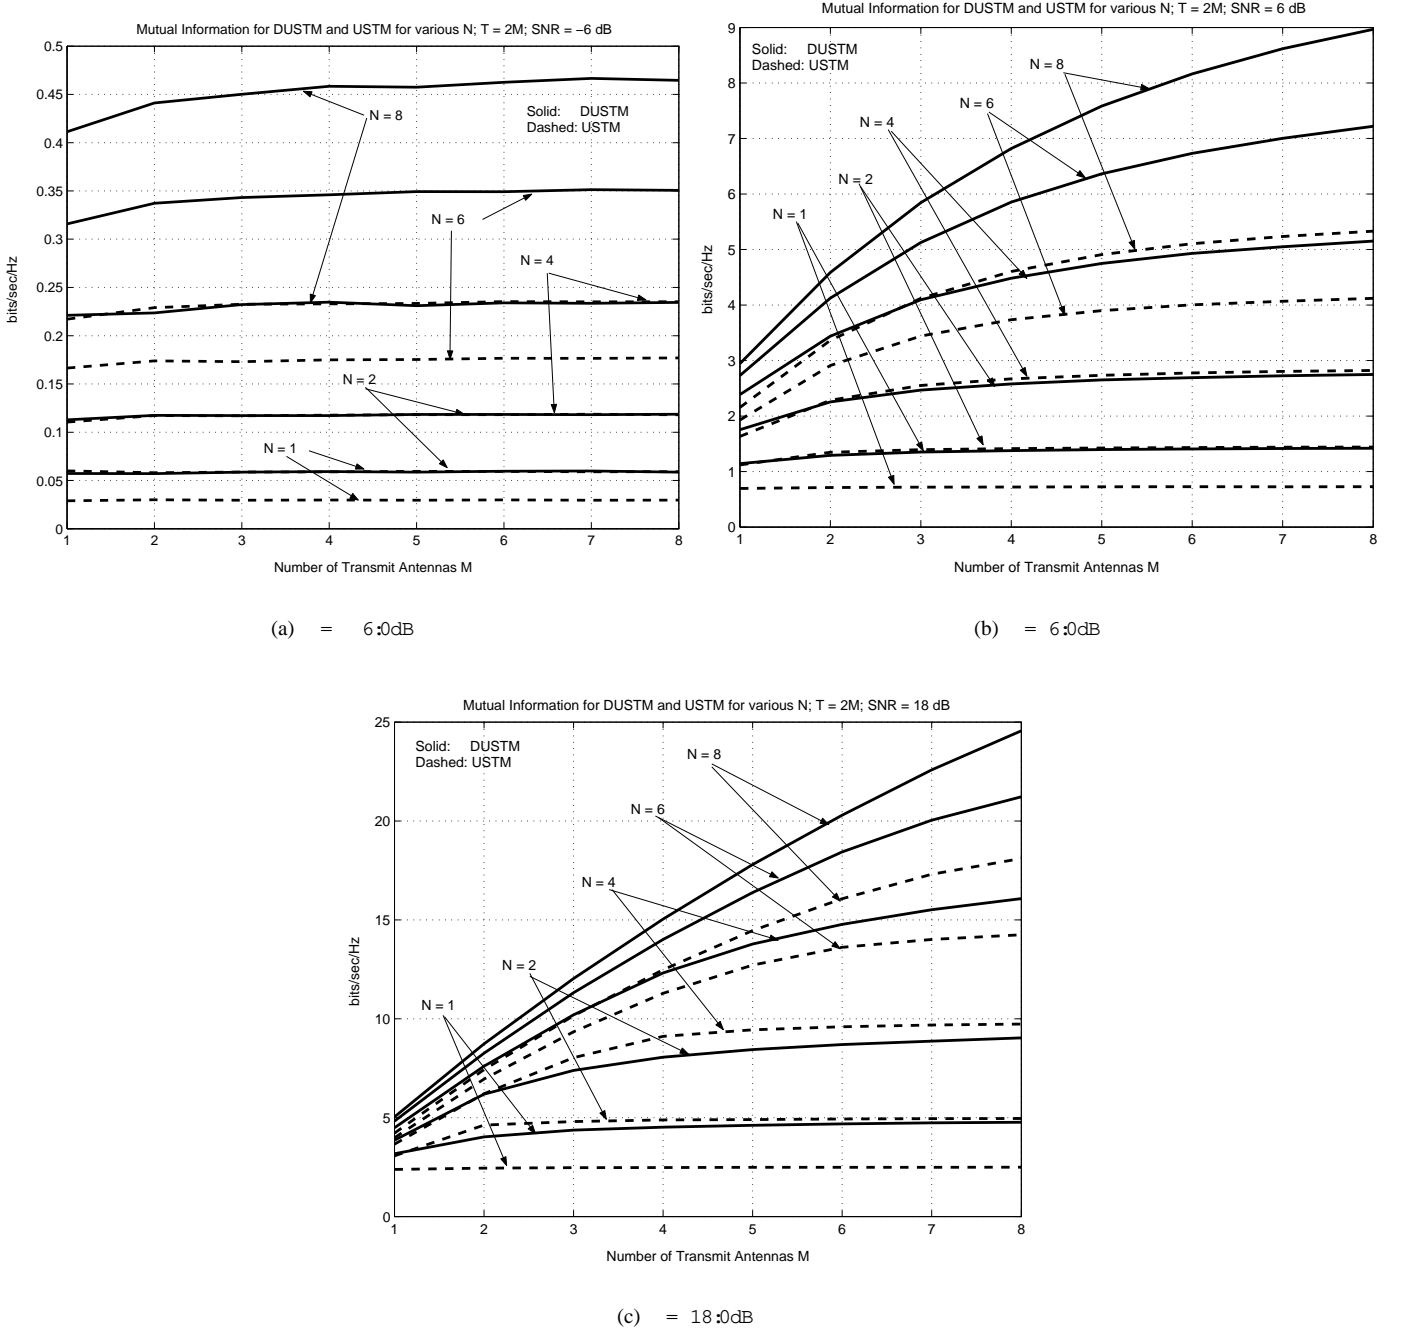

Fig. 1. Plot of normalized mutual information  $\hat{I}_{DUSTM}$  (solid lines) and  $\hat{I}_{USTM}$  (dashed lines) as a function of the number of transmit antennas  $M$  for different receive antenna numbers  $N$  and three SNR levels. The coherence interval  $T$  is chosen to be  $T = 2M$  for proper comparison.

where  $\mathbf{f}^{(n)}(\mathbf{x})$  denotes the  $n$ -th derivative of each of the elements of the vector  $\mathbf{f}(\mathbf{x})$  evaluated at  $\mathbf{x}$ .

*Proof:* This can be proved by successively applying the l'Hospital limit  $k - 1$  times on the numerator and denominator of (45). For the  $p$ th application of this rule ( $p < k$ ) we calculate the limit of  $\mathbf{x}_{p+1} \rightarrow \mathbf{x}_1$ . For example, if  $k = 2$ , both numerator and denominator in (45) have a simple zero in the limit  $\mathbf{x}_2 \rightarrow \mathbf{x}_1$ . Therefore, by taking a single derivative of both and setting  $\mathbf{x}_2 = \mathbf{x}_1$  in the result gives the correct answer. For  $k = 3$ , we first take the  $\mathbf{x}_2 \rightarrow \mathbf{x}_1$  limit as above and then we

take the limit  $\mathbf{x}_3 \rightarrow \mathbf{x}_1$ . Now both top and bottom expressions of the ratio in (45) go to zero quadratically in  $(\mathbf{x}_3 - \mathbf{x}_1)$ . Hence one has to take the second derivative with respect to  $\mathbf{x}_3$  on both top and bottom expressions. For a full proof see [8] ■

## APPENDIX II SMALL ANALYSIS

In this section we will calculate the first four terms in the Taylor expansion in  $\epsilon$  of the mutual information for both the differential and the isotropic USTM cases. The mutual

Fig. 2. (a) Plot of the ratio between the mutual information per symbol for the Differential USTM and the Isotropic USTM (with  $T = 2M$ ) as a function of SNR. For low SNR, the ratio approaches 2, as seen in the previous figure and in agreement with (35), (36). For large SNR the ratio appears to approach 1 (for  $M = N$  and  $M = N=2$ ) and 1.5 (for  $M = 2N$ ), as predicted from (37), (39). For  $M = N$  and  $M = 2N$ , the ratio appears not to depend on the number of antennas for any intermediate  $N$ . (b) Plot of ratio between the mutual information per symbol for the Differential USTM for various antenna numbers to that for  $M = N = 1$ .

information  $I(X; Y)$ , (15) can be rewritten as

$$I(X; Y) = \int dX p(X|Y=0) \log_2 \frac{p(X|Y=0)}{\langle p(X|Y) \rangle} \quad (46)$$

where  $\langle \cdot \rangle$  denotes average over  $Y$ . The simplest way to proceed is to expand both logarithms in powers of  $\epsilon$  and, where convenient, interchange the integration over  $X$  and  $Y$ . The expectation over  $X$  will be denoted by  $E[\cdot]$ .

#### A. Differential USTM

In the case of DUSTM, we see that by taking the ratio of  $p(X|Y = I_M)$  in (17) and  $p(X)$  in (18) the mutual information can be written as

$$I = \frac{E \left[ \text{Tr} \left( X_2 X_1^Y + X_1 X_2^Y \right) \right]}{E \log_2 \exp \left[ \text{Tr} \left( X_2 X_1^Y U + X_1 X_2^Y U^Y \right) \right]} \log_2 e \quad (47)$$

Since  $X_1, X_2$  are zero-mean Gaussian quantities, we only need to specify their variances given by (25). As a result, the first term in (47) can be easily evaluated to give

$$E \left[ \text{Tr} \left( X_2 X_1^Y + X_1 X_2^Y \right) \right] = 2MN \quad (48)$$

To deal with the second term in (47), we also need the following identities for the averages over  $U$ .

$$\langle U_{ij} U_{lk} \rangle = \frac{1}{M} \delta_{il} \delta_{jk} \quad (49)$$

$$\langle U_{i_q j_q} \rangle = 0 \quad (50)$$

where  $r = 0, 1$ . Note that, since  $U$  is an element of  $U(M)$ , all odd moments vanish. However, even moments other than the second one are not easy to evaluate. In fact, even using the simple-looking form of (20) does not simplify matters too much.

To expand the exponent of the second term in (47) in powers of  $\epsilon$  we use the notation

$$A_n = \text{Tr} \left( X_2 X_1^Y U + X_1 X_2^Y U^Y \right)^n \quad (51)$$

We see that due to (50), all odd terms vanish,  $\langle A_{2r+1} \rangle = 0$ . Thus, to 4<sup>th</sup> order in  $\epsilon$ , (47) can be written as

$$I = \frac{2MN}{2} E[A_2] - \frac{4}{24} E[A_4] - \frac{3E[A_2]^2}{2} \log_2 e \quad (52)$$

From (49) we get

$$\langle A_2 \rangle = \frac{2}{M} \text{Tr} \left( X_2 X_1^Y X_1 X_2^Y \right) \quad (53)$$

which results to  $E[A_2] = 2MN^2 + (1 + \epsilon)^2 MN^2$ . Since  $\epsilon = (1 + 2\epsilon)$  is  $O(\epsilon)$  for small  $\epsilon$ , we only need to evaluate the averages involving  $A_4$  and  $A_2^2$  to leading order in  $\epsilon$ , i.e. to  $O(1)$ . Thus, we may neglect the  $O(\epsilon)$  terms in the correlations between  $X_1$  and  $X_2$  (see (25)). As a result,

$$\begin{aligned} E[A_2^2] &= 4N^2(1 + M^2) + O(\epsilon) \\ E[A_4] &= E[A_4] \\ &= 12N(1 + MN) \text{Tr} \left( H U^Y U U^Y \right) + O(\epsilon) \\ &= 12MN(1 + MN) + O(\epsilon) \end{aligned} \quad (54)$$

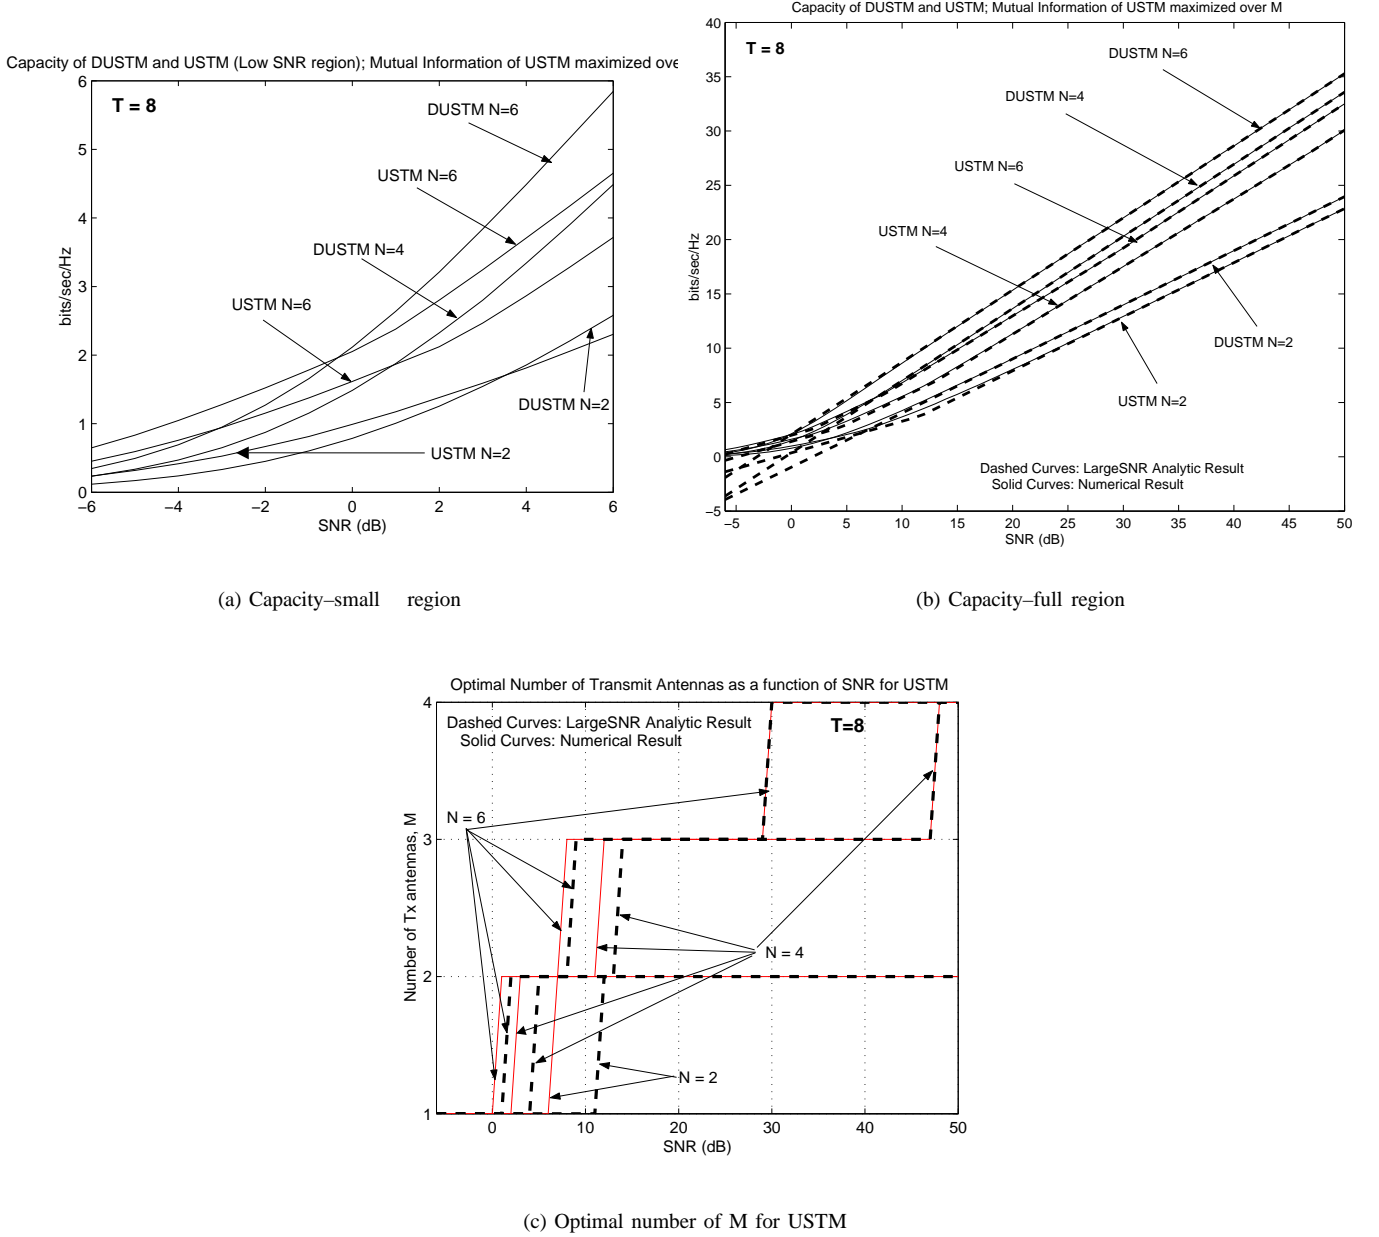

Fig. 3. Plot of capacity of DUSTM and USTM as a function of  $\gamma$ . Here  $T$  is fixed to  $T = 8$ . Fig. 3(a) depicts the small- $\gamma$  region, while Fig. 3(b) shows the full region of  $\gamma$ -values simulated. Fig. 3(c) represents the optimal number of transmitting antennas for USTM as a function of SNR and for various values of  $N$ . The dashed curves in Fig. 3(b),(c) correspond to the analytic expressions valid for large  $\gamma$  (see (37), (39)).

Collecting all terms from above and expanding them to  $O(\gamma^{-4})$  from (34) we obtain the mutual information of (35).

$$E \{ X_{ij}^* X_{kl} \} = \delta_{ik} \delta_{jl} (1 + J_{ii} \frac{1}{N}) \quad (56)$$

### B. Isotropic USTM

In the case of USTM, we will expand  $I_{USTM}$  to order  $\gamma^{-3}$ . As a result, the first term in (55) can be easily evaluated to Here, the analog of (47) is

$$I = E \{ \text{Tr} \{ X^H J_M X \} \} \log_2 e \quad (55)$$

$$E \{ \log_2 \exp \{ \text{Tr} \{ X^H U J_M U^H X \} \} \}$$

where  $U$  is a  $T \times T$  unitary matrix and the  $T \times N$  Gaussian random matrix  $X$  has the following correlations, which follow

$$E \{ \text{Tr} \{ X^H J_M X \} \} = M N = (1) = T N \quad (57)$$

Similarly to the previous section, we define  $B_n$  as

$$B_n = \text{Tr} \{ X^H U J_M U^H X \}^n \quad (58)$$

Then, after expanding the second term in (55) to order  $\epsilon^3$ , it becomes

$$I = \log_2 e \frac{M N}{1} E [h_{B_1 i}] + \frac{2}{2} E [h_{B_2 i}] E [h_{B_1 i}^2] + \frac{3}{6} E [h_{B_3 i}] + 2 E [h_{B_1 i}^3] + 3 E [h_{B_1 i} h_{B_2 i}] \quad (59)$$

Using the orthogonality relation for  $U(T)$  unitary matrices

$$h_{ij} U_{jk} = \frac{1}{T} \delta_{il} \delta_{jk} \quad (60)$$

we can calculate  $h_{B_1 i}$  to be

$$\langle B_1 \rangle = \frac{M}{T} \text{Tr} X^Y X \quad (61)$$

We can now calculate the terms in (59) explicitly:

$$E [h_{B_1 i}] = M N \left( 1 + \frac{M}{T} \right) \quad (62)$$

$$E [h_{B_2 i}] E [h_{B_1 i}^2] = H E [B_2 i] E [h_{B_1 i}^2] = M N \left( 1 + \frac{M}{T} \right) \left( 1 + 2 \frac{M}{T} \right) + O(\epsilon^2) \quad (63)$$

$$E [h_{B_3 i}] + 2 E [h_{B_1 i}^3] + 3 E [h_{B_1 i} h_{B_2 i}] = 2 M N \left( 1 + \frac{M}{T} \right) \left( 1 + 2 \frac{M}{T} \right) + O(\epsilon) \quad (64)$$

Note that the last two equations were only calculated to  $O(\epsilon)$  and  $O(\epsilon^1)$ , given that their proportionality constants in (59) are  $O(\epsilon^2)$  and  $O(\epsilon^3)$ , respectively. Collecting all terms (62), (63) and (64) together in (59), we get the mutual information for USTM to  $O(\epsilon^3)$  expressed in (36).

### APPENDIX III LARGE ANALYSIS

#### A. Differential USTM

We wish to calculate the asymptotic behavior of the DUSTM mutual information for large  $N$ . Using (48), we rewrite the log-ratio of (24) as

$$\log_2 \frac{p(X|j_0)}{p(X)} = \frac{1}{2} \sum_{i=1}^R \log_2 \frac{p_{Y_i}^{X^R}}{p_{Y_i}} + \log_2 k! + \log_2 \frac{\det Y_j^{M \times R+i-1}}{\det Y_j^{\frac{M \times R+i-1}{2}} \Gamma_{M \times R+i-1}(2^p \bar{Y}_j)} \quad (65)$$

where  $y_i$ , for  $i = 1, \dots, R$  are the  $R$  eigenvalues of the matrix  $X^R X_1^Y X_1 X_2^Y$ . The above equation is averaged over the  $M \times N$  Gaussian matrices  $X_1, X_2$  with correlations given by (25). To analyze the large  $N$  behavior, it is convenient to use

the independent  $M \times N$  matrices  $Z$  with  $CN(0;1)$  entries, defined as

$$Z_+ = \frac{X_1 + X_2}{\sqrt{2(1 + 2)}} \quad (66)$$

$$Z = \frac{X_1 - X_2}{\sqrt{2}}$$

Thus  $X_2 X_1^Y X_1 X_2^Y$  can be written as a sum of terms with decreasing powers of  $N$ :

$$X_2 X_1^Y X_1 X_2^Y = H_0^2 + \frac{H_1}{N} + \frac{H_2}{N^2} + O\left(\frac{1}{N^3}\right) \quad (67)$$

where

$$H_0 = N + \quad (68)$$

$$H_1 = \frac{1}{2} (Z_+^Y Z_+ + Z_+ Z_+^Y) N + \text{h.c.} \quad (69)$$

$$H_2 = \frac{1}{2} (N_+^2 + N_-^2) + \frac{1}{2} (Z_+^Y Z_+ + Z_+ Z_+^Y)^2 \quad (70)$$

and  $N_{\pm} = Z_{\pm}^Y Z_{\pm}$ .

To leading order in  $N$ , we can neglect the higher order terms in (67) and only keep the term proportional to  $H_0^2$ . In this case, the eigenvalues of the left hand side of (67) are  $y_i = (n_i)^2$ , where  $n_i$  are the eigenvalues of  $N_+$ . We will need to calculate  $y_i$  to next to leading order, focusing on the  $R$  non-zero ones. To do this we need to express the full eigenvalues  $y_i$  as well as their corresponding eigenvectors as a Taylor expansion in the small parameter  $1/N$ . Applying the normalization condition of the eigenvectors at every order we obtain an expression for the corrections of the eigenvalues in terms of the eigenvalues and eigenvectors of the unperturbed matrix, i.e.  $H_0^2$ . The perturbation analysis of eigenvalues is treated in detail in standard textbooks, see for example [18]. Below we simply quote the answer:

$$y_i = n_i^2 + \frac{n_i^Y H_1 n_i}{N} + \frac{n_i^Y H_2 n_i}{N^2} + \frac{1}{2} \sum_{j \neq i} \frac{n_i^Y H_1 n_j}{n_i^2 n_j^2} + O\left(\frac{1}{N^3}\right) \quad (71)$$

where  $n_i$  are the eigenvectors corresponding to  $n_i$ . The last term in the above equation is summed over all  $j$ , including zeros, and is well behaved because the eigenvalues  $n_i$  are unequal with probability 1. We next observe that, since  $n_i$  are eigenvectors of  $H_0$ ,  $n_i^Y H_1 n_i = 0$ . We now can expand the second term in (65):

$$\frac{1}{2} \sum_{i=1}^R \log_2 \frac{p_{Y_i}^{X^R}}{p_{Y_i}} = \frac{1}{2} \sum_{i=1}^R \log_2 \left( n_i^2 + \frac{n_i^Y H_2 n_i}{N} + \frac{1}{2} \sum_{j \neq i} \frac{n_i^Y H_1 n_j}{n_i^2 n_j^2} + O\left(\frac{1}{N^2}\right) \right) \quad (72)$$

To proceed further, we integrate out  $Z_-$  in the above equation (but not  $Z_+$ ). As a result we get

$$2^{\sum_{i=1}^R p_{\bar{y}_i}} = 2^{\sum_{i=1}^R x_i} \frac{1}{(M-N)R} + O(1) \quad (73)$$

which, after integrating over  $Z_+$  gives

$$2E \sum_{i=1}^R p_{\bar{y}_i} = 2 \sum_{i=1}^R M \frac{R}{2} + O(1) \quad (74)$$

Thus, the first term in the above equation, cancels the first  $O(1)$  term in (65), with the remainder being only of order unity.

We now turn to the asymptotic treatment of the determinants in (65). Since for large  $n$  the non-zero  $y_i$ 's will be large, we may use the asymptotic form of the normalized modified Bessel function

$$I_n(x) \sim \frac{e^x}{\sqrt{2\pi x}} (1 + O(x^{-1})) \quad (75)$$

in the determinant of the denominator in (65) to obtain

$$\begin{aligned} \det_{0 \leq j \leq M} \left( \frac{y_j^{M-R+1}}{4} (1 + O(y_j^{-1})) \right) &= \det_{0 \leq j \leq M} \left( \frac{y_j^{M-R+1}}{4} (1 + O(y_j^{-1})) \right) \\ &= \det_{0 \leq j \leq M} \left( \frac{y_j^{M-R+1}}{4} (1 + O(y_j^{-1})) \right) \\ &= \frac{(1)^{(2M-R-2)R=2}}{(4)^{R=2}} \prod_{i,j < i} y_i^{M-R-1=2} (y_j^{-1}) \end{aligned} \quad (76)$$

The first equality follows from the fact that  $y_i = 2^{-2} (2^{-1} + O(1))$ . Similarly, the Vandermonde determinant can be expressed as

$$\begin{aligned} \det(y_j^{M-R+1}) &= \det(y_j^{M-R+1}) \\ &= \prod_{i,j < i} (y_i^{2(M-R)} (y_j^{-2}) - y_j^{2(M-R)} (y_i^{-2})) \\ &= 1 + O(1) \end{aligned} \quad (77)$$

Taking the logarithm of the ratio of the two determinants (76), (77), we get

$$\begin{aligned} \log_2 \frac{\det(\dots)}{\det(\dots)} &= \sum_{i=1}^M \sum_{j=1}^R \frac{R}{2} \log_2 \frac{R}{2} + \frac{R}{2} \log_2 4 \\ &+ \sum_{i=1}^M \sum_{j=1}^R \frac{1}{2} \log_2 y_i \\ &+ \sum_{i,j < i} \log_2 (y_i + y_j) + \log_2 (1 + O(1)) \end{aligned} \quad (78)$$

Since the eigenvalues of  $H_0$  are equivalent, we need only to evaluate the averages  $E[\log_2 1]$  and  $E[\log_2 (1 + 2)]$  over the  $M \times N$  Gaussian matrix  $Z_+$ . Careful analysis of the correction term shows that it is  $O(\log_2 1)$ .

To calculate these quantities we need the single eigenvalue probability density  $p(x)$  as well as the joint two eigenvalue probability density  $p(x_1, x_2)$  for the random matrix  $H_0 = Z_+^T Z_+$ . Using Telatar's analysis [2], it can be shown that

$$p(x) = \frac{Q}{R} e^{-x} x^{R-1} \quad (79)$$

$$p(x_1, x_2) = \frac{Q}{R} \frac{Q}{R-1} e^{-(x_1+x_2)} x_1^{R-2} x_2^{R-2} \quad (80)$$

where  $p(x_1, x_2)$  is given by

$$p(x_1, x_2) = \sum_{k=0}^{R-1} \frac{k!}{(k+Q)!} L_k^Q(x_1) L_k^Q(x_2) \quad (81)$$

and  $L_k^Q(x)$  is the associated Laguerre polynomial of order  $k$ . Since both  $p(x)$  and  $p(x_1, x_2)$  are finite polynomials in  $x$ ,  $x_1$ ,  $x_2$  times an exponential factor, they can be explicitly integrated using the following identities several times:

$$\begin{aligned} \int_0^\infty x^n \log_2 e^{-x} dx &= n! (n+1) \\ n! \left( 1 + \frac{1}{2} + \frac{1}{n} \right) &= C \log_2 e \end{aligned} \quad (82)$$

$$\begin{aligned} \int_0^\infty \int_0^\infty x_1^n x_2^m e^{-(x_1+x_2)} \log_2 (x_1 + x_2) dx_1 dx_2 \\ = n! m! (n+m+2) \log_2 e \end{aligned} \quad (83)$$

where  $C$  is the Euler constant  $C = 0.57721$ . To somewhat simplify the procedure, we apply the Christofel-Darboux identity (see [19])

$$\begin{aligned} \sum_{k=0}^{R-1} \frac{k!}{(k+Q)!} L_k^Q(x_1) L_k^Q(x_2) \\ = \frac{R!}{(R+Q-1)!} \frac{L_{R-1}^Q(x_1) L_R^Q(x_2) - L_R^Q(x_1) L_{R-1}^Q(x_2)}{x_1 - x_2} \end{aligned} \quad (84)$$

which, in the limit  $R \rightarrow \infty$  becomes

$$p(x_1, x_2) = \frac{R!}{(R+Q-1)!} \frac{L_{R-1}^Q(x_1) L_R^{Q+1}(x_2) - L_R^Q(x_1) L_{R-1}^{Q+1}(x_2)}{x_1 - x_2} \quad (85)$$

As before, the terms outside the curly brackets are common to all sums inside the brackets preceding them. After collecting all terms we can now evaluate the DUSTM mutual information to order  $\mathcal{O}(\log_2 \epsilon)$ .

are the eigenvalues of  $X_1^Y X_1$ , with  $X_1$  a  $M \times N$  Gaussian random, unit-variance matrix. Thus we can use (86).

When  $M > K$ , we have the added complexity that only  $K$   $y_n$ 's are  $O(1)$ . After performing the first  $K$   $t$ -integrals by evaluating them at the poles of these  $K$   $O(1)$   $y$ 's, (31) becomes

$$\begin{aligned} & \exp \left( \text{Tr} X^Y Y X_1 \right) \\ & \frac{C_{TM}}{(M-K)!} \prod_{m=1}^K \frac{e^{y_m}}{(y_m)^{T-K}} \\ & \prod_{m=K+1}^M \int_0^\infty dt_m \frac{e^{-it_m}}{2} \frac{Q_K}{(i_m)^{T-K}} \left( \frac{y_m}{i_m} \right) \\ & \frac{1}{(i_m - i_1)^2} \end{aligned} \quad (92)$$

The  $M-K$  remaining integrals have high-order poles at zero. It is straightforward to show that the above equation becomes

$$\exp \left( \text{Tr} X^Y Y X_1 \right) \frac{C_{TM}}{(M-K)!} \prod_{m=1}^K \frac{e^{y_m}}{(y_m)^{T-K}} \det G + O(1) \quad (93)$$

where  $G$  is an  $(M-K)$ -dimensional square Hankel matrix with elements

$$G_{mn} = \begin{cases} \frac{1}{(T-K-m-n+1)!} & m+n \leq T-K \\ 0 & \text{otherwise} \end{cases} \quad (94)$$

As a result, for  $M > N$  and large  $T$  the mutual information is asymptotically equal to

$$\begin{aligned} I_{USTM} &= (T-M)R \log_2 \frac{T}{M e} + L_1 \log_2 C_{TM} \\ & \log_2 \det G + O(\log_2 T) \end{aligned} \quad (95)$$
