#### Abstract

We present results of $\operatorname{Re}\left(A_{0}\right)$ and $\operatorname{Re}\left(A_{2}\right)$ calculated using HYP staggered fermions on the lattice of $16^{3} \times 64$ at $\beta=6.0$. These results are obtained using leading order chiral perturbation in quenched QCD. Buras's original RG evolution matrix develops a removable singularity for $N_{f}=3$. This subtlety is resolved by finding a finite solution to RG equation and the results are presented.

In the standard model, we can express $\operatorname{Re}\left(A_{I}\right)$ in terms of the matrix elements of the effective weak Hamiltonian between hadronic states as follows:

$$
\begin{align*}
\operatorname{Re}\left(A_{I}\right)= & \frac{G_{F}}{\sqrt{2}}\left|V_{u d} V_{u s}\right|\left[\sum_{i=1,2} z_{i}(\mu)\left\langle Q_{i}(\mu)\right\rangle_{I}\right. \\
& \left.+\operatorname{Re}(\tau) \sum_{i=3}^{10} y_{i}(\mu)\left\langle Q_{i}(\mu)\right\rangle_{I}\right] \tag{1}
\end{align*}
$$

where $V_{i j}$ is an element of CKM matrix. Here, $z_{i}(\mu)$ and $y_{i}(\mu)$ are the Wilson coefficients which are obtained analytically. The hadronic matrix elements $\left\langle Q_{i}(\mu)\right\rangle_{I}$ are defined as
$\left\langle Q_{i}(\mu)\right\rangle_{I}=\left\langle\pi \pi_{I}\right| Q_{i}(\mu)|K\rangle$
Since these matrix elements are in a highly nonperturbative regime of QCD , it is necessary to calculate them using non-perturbative tools such as a numerical method based on lattice gauge theory. In fact, we calculate $\langle\pi| Q_{i}|K\rangle$ and $\langle 0| Q_{i}|K\rangle$ on the lattice using HYP staggered fermions and we construct $\left\langle\pi \pi_{I}\right| Q_{i}|K\rangle$ out of them using chiral perturbation in its leading order [1]. The $\operatorname{Re}(\tau)$ in Eq. (1) is defined as

$$
\begin{aligned}
\operatorname{Re}(\tau) & =-\operatorname{Re}\left(\lambda_{t} / \lambda_{u}\right)=0.002 \\
\lambda_{f} & =V_{f s}^{*} V_{f d}
\end{aligned}
$$

In Eq. (11), $Q_{i}(i=3,4, \cdots, 10)$ represents the QCD and electroweak penguin operators. Since

[^0]$z_{i}, y_{i} \approx 1$, the contribution from the penguin operators to $\operatorname{Re}\left(A_{I}\right)$ is suppressed by $\operatorname{Re}(\tau)$. Therefore, in practice, only the current-current operators $\left\langle Q_{i}\right\rangle(i=1,2)$ can contribute dominantly to $\operatorname{Re}\left(A_{I}\right)$ whereas the contribution from penguin operators is negligible. In the case of the direct CP violation, only penguin operators can contribute to $\epsilon^{\prime} / \epsilon$ [2] and current-current operators do not play any role in it. In this regards, we can say that $\epsilon^{\prime} / \epsilon$ and $\operatorname{Re}\left(A_{I}\right)$ are completely different physics.

In Fig. 1 we show individual channels contributing to $\operatorname{Re}\left(A_{0}\right)$ with the total sum in the last column. The dominant contribution comes from $\left\langle Q_{i}\right\rangle(i=1,2)$ as expected. Each channel is obtained by fitting the data to a function: $f_{1}\left(m_{K}\right)=c_{0}+c_{1} m_{K}^{2}$ and extrapolating to the chiral limit. We use the matching formula given in 34] to convert lattice results into continuum values in the NDR scheme at the scale of $\mu=1 / a$. By assuming that these values are close enough to those for $N_{f}=3$, we run them from $\mu=1 / a$ down to $\mu=m_{c}$, using the RG evolution equation for $N_{f}=3$.

There are two alternative methods to transcribe the $Q_{6}$ and $Q_{5}$ operators to the lattice: the standard (STD) method and the Golterman \& Pallante (GP) method [5]. In the case of $\epsilon^{\prime} / \epsilon$, the dominant contribution to the $\Delta I=1 / 2$ amplitude comes from $\left\langle Q_{6}\right\rangle$ and so there is a big difference in $\epsilon^{\prime} / \epsilon$ between the STD and GP methods [2]. In the case of $\operatorname{Re}\left(A_{0}\right)$, however, the contribution from $\left\langle Q_{6}\right\rangle$ is extremely suppressed by $\operatorname{Re}(\tau)$ and so both methods do not make much difference to $\operatorname{Re}\left(A_{0}\right)$.

Figure 1. $\operatorname{Re}\left(A_{0}\right)$, linear fitting for chiral extrapolation, combined at $\mu=m_{c}$.

In Fig. 2 we show the same kind of plot as in Fig. 1 except for the scale at which the Wilson coefficient and the matrix elements are combined. We set the scale to $\mu=1 / a$ in Fig. 2 and to $\mu=m_{c}$ (charm quark mass) in Fig. The contribution from each individual channel can fluctuate depending on this matching scale but the total sum should be invariant.

In Fig. 3 we show the same kind of plot as in Fig. 1 except for the fitting function. Each channel in Fig. 3 is obtained by fitting the data to a function: $f_{2}\left(m_{K}\right)=c_{0}+c_{1} m_{K}^{2}+c_{2} m_{K}^{4}$ and extrapolating it to the chiral limit. Comparing Fig. 1 and 3] we observe that the dependence of the chiral extrapolation on the fitting function is large. These results are consistent with the experimental value of $\operatorname{Re}\left(A_{0}\right)=33.3 \times 10^{-8} \mathrm{GeV}$ within the systematic and statistical uncertainty.

In Fig. 4 we present individual channels contributing to $\operatorname{Re}\left(A_{2}\right)$ and the total sum in the last column. Each channel is obtained by fitting the data to a linear function $f_{1}\left(m_{K}\right)$ and extrapolating it to the chiral limit. The result of Fig. 4 is slightly lower than the experimental value of $\operatorname{Re}\left(A_{2}\right)=1.5 \times 10^{-8} \mathrm{GeV}$.

Now, let us address a subtle issue on the RG evolution for $N_{f}=3$. The $\Delta S=1$ effective Hamiltonian can be written as follows:
$\mathcal{H}=\frac{G_{F}}{\sqrt{2}} \sum_{i=1}^{10} C_{i}(\mu) Q_{i}(\mu)$

Figure 2. $\operatorname{Re}\left(A_{0}\right)$, linear fitting for chiral extrapolation, combined at $\mu=1 / a$.

The RG (renormalization group) equation for the Wilson coefficient $C_{i}$ is
$\left[\mu \frac{\partial}{\partial \mu}+\beta(g) \frac{\partial}{\partial g}\right] \vec{C}=\gamma^{T}(g, \alpha) \vec{C}$
where $\beta(g)$ is the QCD beta function:
$\beta(g)=-\beta_{0} \frac{g^{3}}{16 \pi^{2}}-\beta_{1} \frac{g^{5}}{\left(16 \pi^{2}\right)^{2}}-\beta_{1 e} \frac{e^{2} g^{3}}{\left(16 \pi^{2}\right)^{2}}$
and $\gamma(g, \alpha)$ is the anomalous dimension matrix:
$\gamma(g, \alpha)=\gamma_{s}\left(g^{2}\right)+\frac{\alpha}{4 \pi} \Gamma\left(g^{2}\right)+\cdots$
$\gamma_{s}\left(g^{2}\right)=\gamma_{s}^{(0)} \frac{\alpha_{s}}{4 \pi}+\gamma_{s}^{(1)} \frac{\alpha_{s}^{2}}{(4 \pi)^{2}}+\cdots$
A solution to the RG equation can be expressed in terms of the evolution matrix.
$\vec{C}(\mu)=U\left(\mu, \mu^{\prime}, \alpha\right) \vec{C}\left(\mu^{\prime}\right)$
Here the RG evolution matrix is, in general,
$U\left(m_{1}, m_{2}, \alpha\right)=T_{g} \exp \left(\int_{g\left(m_{2}\right)}^{g\left(m_{1}\right)} d g^{\prime} \frac{\gamma^{T}\left(g^{\prime}, \alpha\right)}{\beta\left(g^{\prime}\right)}\right)(9)$
In the perturbative expansion, we can express the RG evolution matrix as follows:
$U\left(m_{1}, m_{2}, \alpha\right)=U\left(m_{1}, m_{2}\right)+\frac{\alpha}{4 \pi} R\left(m_{1}, m_{2}\right)$
where $U\left(m_{1}, m_{2}\right)$ represents the pure QCD evolution and $R\left(m_{1}, m_{2}\right)$ describes the additional evolution in the presence of the electromagnetic interaction. The pure QCD evolution matrix which

Figure 3. $\operatorname{Re}\left(A_{0}\right)$, quadratic fitting for chiral extrapolation, combined at $\mu=m_{c}$.

Buras, et al. provided originally 67, is

$$
\begin{align*}
U\left(m_{1}, m_{2}\right)= & \left(1+\frac{\alpha_{s}\left(m_{1}\right)}{4 \pi} J\right) U^{(0)}\left(m_{1}, m_{2}\right) \\
& \cdot\left(1-\frac{\alpha_{s}\left(m_{2}\right)}{4 \pi} J\right) \tag{11}
\end{align*}
$$

where $U^{(0)}\left(m_{1}, m_{2}\right)$ denotes the evolution in the leading logarithmic approximation and $J$ corresponds to the next-to-leading correction.

The $J$ matrix can be expressed as follows:

$$
\begin{align*}
J & =V S V^{-1}, \quad G=V^{-1} \gamma_{s}^{(1) T} V  \tag{12}\\
S_{i j} & =\delta_{i j} \gamma_{i}^{(0)} \frac{\beta_{1}}{2 \beta_{0}^{2}}-\frac{G_{i j}}{2 \beta_{0}+\gamma_{i}^{(0)}-\gamma_{j}^{(0)}} \tag{13}
\end{align*}
$$

where $V$ is a matrix which diagonalize the $\gamma_{s}^{(0) T}$ matrix and $\gamma_{i}^{(0)}$ represents corresponding diagonal elements. Here, note that the $J$ or $S$ matrix is singular if $2 \beta_{0}+\gamma_{i}^{(0)}-\gamma_{j}^{(0)}=0$. In fact, for $N_{f}=3,2 \beta_{0}+\gamma_{i}^{(0)}-\gamma_{j}^{(0)}=0$ when $i=8$, $j=7$. However, since $U\left(m_{1}, m_{2}\right)$ is not singular, this singularity must be removable at the next-to-leading order. After we make a correct combination at the next leading order and remove the singularity, we can make the $U\left(m_{1}, m_{2}\right)$ finite.
$U\left(m_{1}, m_{2}\right)=U_{0}\left(m_{1}, m_{2}\right)+\frac{1}{4 \pi} V A\left(m_{1}, m_{2}\right) V^{-1}(14)$
where, if $a_{j} \neq a_{i}+1\left(\right.$ note that $\left.a_{i} \equiv \gamma_{i}^{(0)} /\left(2 \beta_{0}\right)\right)$,
$A\left(m_{1}, m_{2}\right)=S_{i j}\left[\alpha_{s}\left(m_{1}\right)\left(\frac{\alpha_{s}\left(m_{2}\right)}{\alpha_{s}\left(m_{1}\right)}\right)^{a_{j}}\right.$

Figure 4. $\operatorname{Re}\left(A_{2}\right)$, linear fitting for chiral extrapolation, combined at $\mu=m_{c}$.

$$
\begin{equation*}
\left.-\alpha_{s}\left(m_{2}\right)\left(\frac{\alpha_{s}\left(m_{2}\right)}{\alpha_{s}\left(m_{1}\right)}\right)^{a_{i}}\right] \tag{15}
\end{equation*}
$$

and if $a_{j}=a_{i}+1$,

$$
\begin{align*}
A\left(m_{1}, m_{2}\right)= & \frac{G_{i j}}{2 \beta_{0}} \alpha_{s}\left(m_{2}\right)\left(\frac{\alpha_{s}\left(m_{2}\right)}{\alpha_{s}\left(m_{1}\right)}\right)^{a_{i}} \\
& \cdot \ln \left(\frac{\alpha_{s}\left(m_{2}\right)}{\alpha_{s}\left(m_{1}\right)}\right) \tag{16}
\end{align*}
$$

Here, note that the $A$ matrix is finite while $J$ matrix is singular.

In the case of the $R\left(m_{1}, m_{2}\right)$, the same kind of removable singularity makes the RG evolution much more complicated, which we will present in Ref. [8].
