A Study of U ltraviolet R enorm alon A mbiguities in the $D$ eterm ination of $s$ from $D$ ecay<br><br>CERN TH-D ìvision, CH-1211 G eneva 23, Sw itzerland

## A bstract

T he divergent large-order behaviour of the perturbative series relevant for the determ ination of $s$ from decay is controlled by the leading ultraviolet ( $\mathrm{U} V$ ) renorm alon. Even in the absence of the rst infrared ( $\mathbb{R}$ ) renorm alon, an am biguity of order ${ }^{2}=m^{2}$ is introduced. W em ake a quantitative study of the practicalim plications of th is am biguity. W e discuss them agnitude ofU V renorm alon corrections obtained in the large $\mathrm{N}_{\mathrm{f}} \lim$ 止, which, although unrealistic, is nevertheless interesting to som e extent. W e then study a num ber of im proved approxim ants for the perturbative series, based on a change of variable in the B orel rep resentation, such as to displace the leading $U V$ renorm alon singularity at a larger distance from the origin than the rst $\mathbb{R}$ renorm alon. T he spread of the resulting values of $s\left(m^{2}\right)$ obtained by di erent approxim ants, at di erent renorm alization scales, is exhibited as a m easure of the underlying am biguities. $F$ inally, on the basis of $m$ athem atical $m$ odels, we discuss the prospects of an actual im provem ent, given the signs and $m$ agnitudes of the com puted coe cients, the size of $s\left(\mathrm{~m}^{2}\right)$ and what is know $n$ of the asym ptotic properties of the series. O ur conclusion is that a realistic estim ate of the theoretical error cannot go below $s\left(m^{2}\right) \quad 0: 060$, or $s\left(m_{z}^{2}\right) \quad 0: 006$.

## 1. Introduction

The possibility of measuring sfrom -decay has been extensively studied in a series of interesting papers, in particular by $B$ raaten, $N$ arison and $P$ ich [in [īn]. The relevant quantity is $R=(!\quad+$ hadrons $)=(!+l)$, with $l=e$; At present [़్మ the A LEPH collaboration nds

$$
\begin{equation*}
(R)_{\exp }=3: 645 \quad 0: 024: \tag{1.1}
\end{equation*}
$$

B ased on this result, it is argued, if the form alism of QCD sum rules is assum ed, according to SVZ [- $[-1$, that

$$
\begin{equation*}
s\left(m^{2}\right)=0: 355 \quad 0: 021 \tag{12}
\end{equation*}
$$

and nally

$$
\begin{equation*}
s\left(m_{z}^{2}\right)=0: 121 \quad 0: 0016(\exp ) \quad 0: 0018(\text { th })=0: 121 \quad 0: 0024: \tag{1.3}
\end{equation*}
$$

 precise!

In defence of this $m$ ethod $[\underline{1}[1]$ in one can certainly point out that $R$ has several com bined advantages. D ropping som e inessential com plications, $R$ is an integral in $s$ of a spectral function $R$ ( $s$ ) which is the analogue of $R_{e^{+}} e$ ( $s$ ) but for the case of charged weak currents. Thus, rst, $R$ is even more inclusive than $R_{e^{+} e}(s)$ and one expects that the asym ptotic regim e is $m$ ore precocious for $m$ ore inclusive quantities. Second, one can use analyticity in order to transform the relevant integral into an integral over the circle $j \mathfrak{j} j=\mathrm{m}^{2}$ 傗]. This not only gives some con dence that the appropriate scale of energy for the evaluation of $R$ is of order $m$, but also show $s$ that the integration over the low-energy dom ain helps very much in sm earing out the com plicated behaviour in the resonance region. A lso im portant is the presence of a phase-space factor that kills the sensitivity of the spectral function near Res = $m^{2}$, where there is a gap of validity of the asym ptotic approxim ations due to the vicinity of the cut singularities and also to the nearby charm threshold. On the circle $\dot{\beta} j=m^{2}$, asym ptotic form ulae should be approxim ately valid for the correlator. The perturbative com ponent ofR ( $s$ ) is known up to term soforder $s\left(m^{2}\right)^{3}[12]$. O ne can hope to get som e control of the non-perturbative corrections by using the operator
product expansion and som e estim ate (either experim ental or by som em odel) of the dom inant condensates, in the spirit of the QCD sum nules 恛].

This series of virtues of $R$ is indeed realbut would not be su cient in itself to justify the precision on $s\left(m^{2}\right)$ which is claim ed. The realpoint is that no corrections of order $1=\mathrm{m}^{2}$ are assum ed to exist. The fact that there is no operator $w$ th the corresponding dim ension in the short distance expansion is not su cient, because there could be non-leading corrections in the coe cient function of the leading operator. W e think it is a fair statem ent that there is no theorem that guarantees the absence of
${ }^{2}=m^{2}$ term $s$ in $R$ in the $m$ assless lim it; no theorem that proves that term s of order
${ }^{2}=m^{2}$ cannot arise from the $m$ echanism that generates con nem ent. But even if in principle the above theorem would exist, still, in practice, there would be am biguities on the leading-term perturbative expansion of order ${ }^{2}=m^{2}$ from the ultraviolet renorm alon sequence associated to the divergence of the perturbative series for the
 cussion of the im pact of $V V$ renom alon am biguities on the determ ination of $s\left(m^{2}\right)$. O $n$ the basis of the accum ulated know ledge on renorm alon behaviour, we address the question of what is the theoretical error on $s\left(\mathrm{~m}^{2}\right)$ and exam ine possible ways to decrease it. W e discuss the m agnitude of UV renom alon corrections obtained from explicit calculations [1] are nevertheless interesting to som e extent. We then study a num ber of im proved approxim ants for the perturbative series, based on a change of variable in the B orel representation $[10$ larger distance from the origin than the rst infrared ( $\mathbb{R}$ ) renorm alon. The spread of the resulting values of $\mathrm{s}\left(\mathrm{m}^{2}\right)$ obtained by di erent approxim ants, at di erent renor$m$ alisation scales is exhibited as a $m$ easure of the underlying am biguities. Finally, on the basis ofm athem aticalm odels, we discuss the prospects of an actualim provem ent, given the signs and the $m$ agnitudes of the com puted coe cients, the size of $s\left(m^{2}\right)$ and what is known of the asym ptotic properties of the series. O ur conclusion is that a realistic extim ate of the theoretical error cannot go below $s\left(m^{2}\right)$ 0:060, or ${ }_{s}\left(m_{z}^{2}\right) \quad 0: 006$.

The organisation of this article is as follow s. In sect 2 we sum $m$ arise the basic form ulae and discuss di erent procedures to do the integration over the circle that di er by resum $m$ ing or not an in nite series of $\backslash$ large ${ }^{2}$ term $\mathrm{s}^{\prime \prime}$. W e discuss the
relative $m$ erits of the various procedures and their scale dependence. In sect. 3 we introduce the problem s related to the divergence of the perturbative series, we review the Borel transform $m$ ethod and the renorm alon singularities. In sect. 4 we derive som e useful form ulae obtained in the B orel space after integration on the circle. In sect. 5 we consider the explicit form for the leading $U V$ renom alon singularity derived in perturbation theory in the large $\mathrm{N}_{\mathrm{f}} \operatorname{lm}$ it, $\mathrm{N}_{\mathrm{f}}$ being the number of avours. This lim it is not $m$ eant to be realistic, but, for orientation, we evaluate the quantitative im pact that such an UV renorm alon would have on the determ ination of $s\left(m^{2}\right)$. $W$ e nd that this e ect is rather sm all. In sects.6,7, which contain the $m$ ain original results of this w ork, we introduce and study a num ber of im proved approxim ants that could in principle suppress the am biguity from the leading $U V$ renorm alon. W e study the com binede ects ofdi erent, a prioriequivalent, procedures, di erent accelerators of convergence and di erent choices of the renorm alisation scale. W e also study in a simple $m$ athem atical $m$ odel under which conditions for the known coe cients of the series the accelerator $m$ ethod leads to a better approxim ation of the true result. F inally, in sect. 8 we present our conclusion.

## 2. B asic Form ulae and Truncation A mbiguities

The quantity of interest is the integral over the hadronic squared $m$ ass $s$ in decay of a function $R(s)$ analogous to $R_{e^{+}}$e ( $s$ ), weighted by a phase-space factor. In

$$
\begin{equation*}
R=\sum_{0}^{m^{2}} \frac{d s}{m^{2}} 21{\frac{s}{m^{2}}}^{!} 1+\frac{2 s}{m^{2}} R(s): \tag{2.1}
\end{equation*}
$$

$R(s)$ is proportional to the im aginary part of a current-current correlator:

$$
\begin{equation*}
R(s)=\frac{N}{I m} \quad(s)=\frac{N}{2 i}[(s+i) \quad(s \quad i)]: \tag{22}
\end{equation*}
$$

The nom alization factor N is de ned in such a way that, in zeroth order in perturbation theory, $R(s)=3$. In tum, the correlator ( $s$ ) is related to the A dler fiunction D (s), de ned in such a way as to rem ove a constant:

$$
\begin{equation*}
D \quad(s)=s \frac{d}{d s} N \quad(s): \tag{2.3}
\end{equation*}
$$

By rst integrating by parts and then using the $C$ auchy theorem one obtains for $R$ the result

The Adler function $D$ has a perturbative expansion of the form :
where $\mathrm{a}=\mathrm{s}=, \mathrm{D}^{0}=3(1+)$ where is a known sm allelectrow eak correction, and, for $N_{f}=3$ in the $\overline{\mathrm{MS}}$ schem e ,

$$
\begin{align*}
\mathrm{D}_{1}= & 1 \\
\mathrm{D}_{2}= & \frac{11}{2} \quad 4 \quad(3)+\frac{\mathrm{C}_{\mathrm{A}}}{12} \quad \frac{\mathrm{C}_{\mathrm{F}}}{8}=1: 640 \\
\mathrm{D}_{3}= & \frac{151}{18} \quad \frac{19}{3} \quad(3) 4^{2}+2 \mathrm{C}_{\mathrm{A}} \frac{31}{6} \quad \frac{5}{3}((3)+(5)) \\
& +2 \mathrm{C}_{\mathrm{F}} \frac{29}{32} \quad \frac{19}{2}(3)+10(5)+\mathrm{C}_{\mathrm{A}}^{2} \quad \frac{799}{288}  \tag{3}\\
& +\mathrm{C}_{\mathrm{A}} \mathrm{C}_{\mathrm{F}} \quad \frac{827}{192}+\frac{11}{2}(3)+\mathrm{C}_{\mathrm{F}}^{2} \quad \frac{23}{32}=6: 371 ;
\end{align*}
$$

where $(3)=1: 20206$ and $(5)=1: 03693, C_{A}=N_{C}=3$ and $C_{F}=\left(\mathbb{N}_{C}^{2} \quad 1\right)=\left(2 N_{C}\right)=$ $4=3$. The quantity $=\left(11 C_{A} \quad 2 N_{f}\right)=12$ is the rst beta function coe cient ${ }^{[ }[\underline{2} 2]$ :

$$
\begin{equation*}
\frac{2 d a\left({ }^{2}\right)}{d^{2}}=a\left({ }^{2}\right) ; \quad(a)=a^{2}(1+0 a+:::) \tag{2.7}
\end{equation*}
$$

$\left(=9=4, \quad 0=16=9\right.$ for $\left.N_{f}=3\right)$.
The expansion in eq. (2-5]) de nes the A dler function at all com plex $s$ w th a cut for $s>0$. In the spacelike region, where $s<0, a(s)$ is real and given asym ptotically by $\left({ }^{2}>0\right)$ :

$$
\begin{equation*}
\frac{1}{a(s)}=\frac{1}{a\left({ }^{2}\right)}+\quad \log \frac{s}{2}=\log \frac{s}{2}: \tag{2.8}
\end{equation*}
$$

If we want $a(s)$ at som e complex value of the argum ent, e.g. $s=$ jsjexp (i ), we can use the form ula

$$
\begin{equation*}
a(s)=\frac{a(\dot{j} j)}{1+a(\dot{j} j) i} \tag{2.9}
\end{equation*}
$$

where the angle is on the upper tip of the cut for s real and positive, + on the lower tip and zero on the negative real axis. The m ore accurate two-loop expression is given by

$$
\begin{equation*}
a(s)=\frac{a(\dot{\beta} j)}{1+a(\dot{j} j) i+a^{\prime}(\dot{j} j) \log (1+a(\dot{j} j) i)}: \tag{2.10}
\end{equation*}
$$

$T$ he expansion for $R(s)$ (for $s$ real and positive) can be obtained from that ofD by the relation

$$
\begin{equation*}
R(s)=\frac{1}{2 i}_{j^{0} j=s}^{I} \frac{d s^{0}}{s^{0}} D \quad\left(s^{0}\right): \tag{2.11}
\end{equation*}
$$

Perform ing the integration by using the expansion for $D$ in eq. ( $\left(\underline{-} . \mathbf{S}_{1}^{\prime}\right)$ and the expression in eq. ( 2.1 Ī ${ }^{-1}$ ) for a com plex argum ent, one obtains

$$
\begin{equation*}
\mathrm{R}(\mathrm{~s})=\mathrm{D}^{0} 1+\mathrm{F}_{1} \mathrm{a}(\mathrm{~s})+\mathrm{F}_{2} \mathrm{a}^{2}(\mathrm{~s})+\mathrm{F}_{3} \mathrm{a}^{3}(\mathrm{~s})+::: ; \tag{2.12}
\end{equation*}
$$

and

$$
\begin{equation*}
F_{1}=D_{1} ; \quad F_{2}=D_{2} ; \quad F_{3}=D_{3} \quad \frac{22}{3}: \tag{2.13}
\end{equation*}
$$

The origin of the ${ }^{2}{ }^{2}=3$ term is easily understood. By using the one-loop expansion for a (s), eq. ( $\overline{2} \cdot \overline{-1})$, one gets

$$
\begin{equation*}
R(s)=D^{0} 1+\frac{1}{2 i} \log \frac{1+i a(s)}{1 \text { i } a(s)}+:::=D^{0} 1+a(s) \frac{{ }^{2}{ }^{2} a^{3}(s)}{3}+::: \tag{2.14}
\end{equation*}
$$

W e have the follow ing observations on this result. F irst, for $\mathrm{N}_{\mathrm{f}}=3$, the coe cients $\mathrm{F}_{1 ; 2 ; 3}$ in the expansion of R (s) for decay coincide w th those of $\mathrm{R}_{\mathrm{e}^{+}} \mathrm{e}$ because the potentially di erent term sproportional to $\left(Q_{i}\right)^{2}$, w ith $Q_{i}$ being the quark charges, vanish in this case. Second, we observe that eq. ( 2 of higher-order term $s$ in the quantity ${ }^{2} a^{2}{ }^{2}, 0: 7 \mathrm{w}$ ith $\mathrm{a}=\mathrm{a}\left(\mathrm{m}^{2}\right)$. Note that a sim ilar problem of truncation arises when the integration over the circle in eq. (2, $\overline{2} .4)$ is perform ed. In the early treatm ents of this problem (e.g. in ref. $\overline{\underline{k}}]$ ) the expression of a( s), which appears on the circle, is taken from eq. $\bar{Q}-10$ ) and expanded in a consistently to the order $\mathrm{a}^{3}$. W ith this procedure, one obtains

$$
\begin{equation*}
\mathrm{R}^{(\mathrm{BNP})}=\mathrm{D}^{0} 1+\mathrm{H}_{1} \mathrm{a}\left(\mathrm{~m}^{2}\right)+\mathrm{H}_{2} \mathrm{a}^{2}\left(\mathrm{~m}^{2}\right)+\mathrm{H}_{3} \mathrm{a}^{3}\left(\mathrm{~m}^{2}\right)+::: ; \tag{2.15}
\end{equation*}
$$

with

$$
\begin{equation*}
H_{1}=1 ; \quad H_{2}=5: 2023 ; \quad H_{3}=26: 3666: \tag{2.16}
\end{equation*}
$$

W ew ill refer to this result as BNP form ula (for the authors of ref. [ī]). M ore recently in ref. $\left[\begin{array}{l}\overline{4}\end{array}\right]$ it was advocated that a better procedure for perform ing the integration on the circle is to keep the full three-loop expression for a ( jंje ${ }^{i}$ ), according to the formula

It is this procedure which is currently adopted (LeD iberder-P ich, or LP m ethod). At xed experm ental value ofR, the two procedures lead to values of $s\left(m^{2}\right)$ that di er by term sof order $s\left(m^{2}\right) \quad\left({ }^{2} a^{2}{ }^{2}\right) a^{2}$ 0:01 or $\left({ }^{2} a^{2}{ }^{2}\right)^{2} a$ 0:05. These $\backslash$ large
${ }^{2}$ term s" always arise when one goes from the spacelike to the tim elike region (e.g. sim ilar term s arise [ fragm entation functions to structure functions). There have been $m$ any discussions in the past on the opportunity of resum $m$ ing these term $s$ [2] argum ent to consider the expansion for $D$ ( $s$ ) in som e respect superior to that for $R(s)$ it could be worthw hile at low energies to keep the expression in eq. ( 2.1 its resum $m$ ed form rather than to expand in ${ }^{2} a^{2}{ }^{2}$. A glance at eqs. (2, show s that, for $n$ 3, there are no explicit \large ${ }^{2}$ term S " in the coe cients $D_{n}$ of the expansion for $D$. Sim ilarly when the integration on the circle is perform ed w ith the complete formula for $a\left(\dot{j} \dot{j}^{i}\right)$ all term $s$ are kept up to order $a^{3}\left({ }^{2} a^{2}{ }^{2}\right)^{n}$, i.e. up to order $a^{3}$ one expands in a but keeps ${ }^{2} a^{2}{ }^{2}$ unexpanded. Sure enough this sequel of term s exists in reality, so why not take them into account? H ow ever, the counterargum ent is that there are in perturbation theory term $s$ involying ${ }^{2}$ that arise from origins other than the spacelike-tim elike connection and, in any case, there are $m$ any term $s$ of the sam e generalm agnitude (for exam ple, the term proportional to ${ }^{2}$ in $\mathrm{D}_{3}$, eq. (2.- Z$)$ ), so that the advantage of keeping this particular class of term s is likely to be com pletely ilhusory.

O ne can further consider the scale dependence of the di erent procedures. O ne can write

$$
\begin{equation*}
\mathrm{R}^{(\mathrm{BNP})}=\mathrm{D}^{0} 1+\mathrm{H}_{1} \mathrm{a}\left({ }^{2}\right)+\mathrm{H}_{2} \mathrm{a}^{2}\left({ }^{2}\right)+\mathrm{H}_{3} \mathrm{a}^{3}\left({ }^{2}\right)+::: ; \tag{2.18}
\end{equation*}
$$

where

$$
\mathrm{H}_{1}\left({ }^{2}\right)=\mathrm{H}_{1}
$$

$$
\begin{align*}
& \mathrm{H}_{2}\left({ }^{2}\right)=\mathrm{H}_{2} \quad \mathrm{H}_{1} \quad \log \frac{\mathrm{~m}^{2}}{2} \\
& \mathrm{H}_{3}\left({ }^{2}\right)=\mathrm{H}_{3} \quad 2 \mathrm{H}_{2} \quad \log \frac{\mathrm{~m}^{2}}{2}+\mathrm{H}_{1} \quad{ }^{2} \log ^{2} \frac{\mathrm{~m}^{2}}{2} \quad{ }^{0} \log \frac{\mathrm{~m}^{2}}{2} \text { : } \tag{2.19}
\end{align*}
$$

A nalogously, we can study the scale dependence in the LP m ethod. In this case we have

where the $\tilde{D}_{n}$ coe cients are related to the $D_{n}$ as the $H_{n}$ to the $H_{n}$ in eqs. ( $\overline{2} \overline{1} \overline{1} \bar{d}_{\text {) }}$.
The results of the LP and BNP methods are shown in gin, where, assum ing a $m$ easured value of 3.6 for $R$, we show the corresponding determ ination of $s\left(m^{2}\right)$ as a function of the renorm alization scale. For com parison, we also show (dashed curve) the determ ination obtained with a sim pli ed LP m ethod, in which we use the one-loop expression eq. (2.-9. $\underline{l}^{\prime}$ ) for a. For $>1 \mathrm{GeV}$ there is less dependence if the resum $m$ ed expressions are used. This stability is often taken as a possible indication that resum $m$ ing is better.

In conclusion, we agree that the resum $m$ ed form ulae provide a less ambiguous result $w$ ith respect to a change of scale than the unresum $m$ ed expression. H ow ever, it is true that a priori it is not possible to guarantee that a m ore accurate result is obtained in one way or the other. As a consequence the spread shown in gitit for di erent choices of and of procedure is to be taken as a realam biguity. In particular the large discrepancy at 1 GeV is a genuine signal of trouble, especially in view of the fact that several proposed scale- xing procedures lead to $s m$ all values of , e.g.
 physical considerations, because the average hadronic $m$ ass is well below $m$. So, on the one hand, one cannot sensibly reject the option ofsm allvalues of . O $n$ the other hand, the corresponding value of $a\left(m^{2}\right)$ becom es very am biguous at sm all .

## 3. $R$ enorm alons and $B$ orel $T$ ransform ation

In the follow ing discussion we rst study the properties ofD (s) in itself, and only later we consider the integration over the circle. The problem that we now consider

Figure 1: The value of $s\left(\mathrm{~m}^{2}\right)$ obtained from $R=3: 6$, as a function of the renom alization scale .
is the well known fact that the series for $D$ is divergent. Indeed one can identify sequences of diagram $s$, depicted in $g$.' in, called \renom alon" term s'[1] provide the leading behaviour at large $n$ for the $n$-th coe cient of the expansion for D . The renom alon contribution is of the form :

n bubbles

Figure 2: Renorm alon diagram sfor a two-point correlator.

$$
\mathrm{D}_{\mathrm{n}} \quad \mathrm{C}_{\mathrm{k}} \mathrm{n} \mathrm{n}^{\mathrm{k}} \quad \overline{\mathrm{k}}_{\mathrm{n}}[1+\mathrm{O}(1=\mathrm{n})] \quad(\mathrm{n} \text { large }):
$$

$N$ ote the n ! behaviour which im plies that the series is divergent. Here, $\mathrm{C}_{\mathrm{k}}$ and $\mathrm{k} \quad 0$ are not know $n$ for the real theory but only, to som e extent, in the large $\mathrm{N}_{\mathrm{f}}$ expansion $[1]$

$$
\begin{align*}
& \mathrm{k}=1 ; 2 ; 3 ;::: \text { U ltraviolet (UV) Renom alons } \\
& \mathrm{k}=+1 \text { (?);+2;+3;::: Infrared ( } \mathbb{R} \text { ) Renom alons } \tag{32}
\end{align*}
$$

In the above list we om it the contribution from instantons, which appear at rather large values of $k$. They have been com puted in ref. [1s.] and show $n$ to be sm all. The $U V$ or $\mathbb{R}$ renorm alons arise from the lim its oflarge or sm allvirtuality, respectively, for the exchanged gluon (s). A s hinted by the question $m$ ark, the $k=+1 \mathbb{R}$ renorm alon is probably absent in perturbation theory, but the issue is not really settled $\left.{ }_{1}^{1} \overline{1}-12 \overline{1} \overline{1} 1\right]$. The absence of this term is necessary for the consistency of the assum ption that all non-perturbative e ects can be absorbed in the condensates. In the follow ing we will assume that the $k=1 \mathbb{R}$ renorm alon is indeed absent.

In view of the divergence of the perturbative expansion, one can possibly give a $m$ eaning to the quantity

$$
\begin{equation*}
d(a)=\frac{D}{D^{0}} \quad 1=D_{1} a+D_{2} a^{2}+D_{3} a^{3}+::: \tag{3.3}
\end{equation*}
$$

by the Borel transform $m$ ethod $\left.{ }_{[1-1}^{2}\right]$. O ne de nes the perturbative expansion of the B orel transform $B(b)$ of $d(a)$ by rem oving the $n$ ! factors:

$$
\begin{equation*}
B(b)={ }_{n=0}^{x^{1}} D_{n+1} \frac{n^{n}}{n!}=D_{1}+D_{2} b+D_{3} \frac{b^{2}}{2}+::: \tag{3.4}
\end{equation*}
$$

Then, form ally

$$
\begin{equation*}
d(a)=z_{0}^{z_{1}} d b e e^{b=a} B(b) \tag{3.5}
\end{equation*}
$$

in the sense that the expansion for $B$ (b) reproduces the expansion for $d$ (a) term by term. W hat is needed ford(a) to be well de ned is that the integral converges (this cannot be true at all s $[1]$ this problem can be neglected in our context) and that B (b) has no singularities in the integration range. But, as already $m$ entioned, the large-n expansion ofB (b) leads to singularities on the real axis. In fact, at large $n, B(b)$ is essentially given by a geom etric series:

B (b) $\quad C_{k}^{x} n_{n}^{k} \frac{b^{!}}{k^{n}} \quad C_{k} \quad(k+1) 1 \quad \frac{b^{!}}{k^{k}} \quad+$ less singular term $s$
so that it is singular at $b=k=$. T hus the $U V$ renorm alons correspond to singularities at $\mathrm{b}=1=$; $2=;:::$ and the $\mathbb{R}$ renorm alons at $+2=;+3=;:::$ A sa consequence, the convergence radius of the expansion for $B$ (b) near the b-origin is determ ined by the $U V$ renorm $a l o n$ at $b=1=$, independent of the existence of the $\mathbb{R}$ renom alon at $\mathrm{b}=+1=$.

Thus, the perturbative expansion for $B$ (b) can be directly used only to perform the integration up to $b=+1=$. The contribution from $b=+1=$ up to $b=1$, where the expansion is not valid, could typically lead to term sof order ${ }^{2}=s$ (or even w orse). For exam ple, if $B(b)$ is su ciently well behaved at $b=+1=$ and at $b=1$,

$$
\begin{equation*}
d(a)={ }_{1=}^{Z_{1}} d b e{ }^{b=a} B(b) \quad a B(1=) \exp (\quad 1=a) \quad a B(1=)^{2}=s ; \tag{3.7}
\end{equation*}
$$

where we used $a^{1}$, $\log \left(s={ }^{2}\right)$ and the fact that the exponential cuts aw ay all large-b contributions so that $B(b)$ was approxim ated by its value near $b=+1=$. From a di erent point of view, at large $n$, the series for $d(a)$ is dom inated by the $U V$ renorm alon behaviour $w$ ith $D_{n} n n!()^{n}$. At xed small a, the individualterm $s$ $D_{\mathrm{n}} \dot{\beta}^{\mathrm{n}}$ rst decrease $w$ ith n , then atten out and eventually increase because of the $n!$ factor. The best estim ate of the sum is obtained by stopping at the minim um, for $n \quad n_{\text {opt }}$, given by $D_{n} \dot{\beta}^{n} \quad D_{\mathrm{n}} 1 \dot{\beta}^{\mathrm{n}}{ }^{1}$, or $\mathrm{n}_{\text {opt }} \quad 1=\mathrm{a}$. From the theory of asym ptotic series $\left.\underline{\underline{p}}_{\underline{1}}^{1} \overline{1}\right]$, the corresponding uncertainty $d(a)$ is of order $\rrbracket_{n_{\text {opt }}} \dot{A}^{n^{\text {opt }}}$ :

$$
\begin{array}{lll}
D_{n_{\text {opt }}} \dot{a}^{\mathrm{n}_{\text {opt }}} & (1=a) \quad(1=a)!(a)^{(1=a)} \\
& (1=a) \quad(1=a)^{(1=a)} e^{(1=a)} \\
& (1=a) \quad e^{(1=a)} \overline{2=a}(a)^{(1=a)}  \tag{3.8}\\
2=a & { }^{2}=s \quad \text { logarithm } s ;
\end{array}
$$

(where the Stirling approxim ation was used: $n!{ }^{\prime} n^{n} e^{n}{ }^{p} \overline{2 n}$ ). Thus one could im prove the accuracy of the perturbative expansion by com puting $m$ ore subleading term suntiln $\quad n_{\text {opt }}$ is reached and then add a residualterm of order ${ }^{2}=s$. $N$ ote that the estim ate $n_{\text {opt }} \quad 1=a \quad 4$ indicates a rather sm all value. H ow ever this estim ate is obtained from the behaviour of the leading UV renorm alon series, while there is no altemation of signs and in general no evidence of renom alon behaviour in the few know $n$ term $s$ of the series.

W hile an accuracy of order ${ }^{2}=s$ is what one gets in practioe from the threeloop expression of $d(a)$, it is true that, in principle, if there is no $\mathbb{R}$ renorm alon at $\mathrm{b}=+1=, \mathrm{d}(\mathrm{a})$ can be better de ned. In fact, as the location of the leading UV renorm alon at $b=1=$ is not in the integration range, there is the possibility of de ning $B(b)$ by analytic continuation up to $b=+2=$. If this is realised then the rem aining am biguity, of order $\left({ }^{2}=s\right)^{2}$, is unavoidable because the corresponding singularity $a t b=+2=$ is on the realaxis, so that an arbitrary procedure to go around it must be de ned and the di erence between two such procedures would be of that order. H ow ever, since operators of dim ension 4 do exist in the operator expansion, this am biguity can be reabsorbed in the non-perturbative condensate tem $s$ [ījen W e also understand that the absence of the $\mathbb{R}$ renom $a l o n$ at $b=+1=$ is necessary for the consistency of the SV Z [塥] approach because operators of dim ension 2 are absent in this channel. If there would be a singularity at $b=+1=$ the corresponding ambiguity could not be absorbed in a condensate. There are indeed indications in
perturbation theory that the rst $\mathbb{R}$ renorm alon does not appear' $[1]$ there could be non-perturbative sources ofbreaking of the operator expansion at nonleading level. A fter all no theory of con nem ent could be built up from perturbation theory and renorm alons. But, in practioe, independent of the existence of the $\mathbb{R}$ renorm alon at $b=+1=$, the accuracy to be expected from the rst three term $s$ in the expansion for $d(a)$, as they have been used so far in the actual determ ination of $s$, is of order ${ }^{2}=s$.
4. The Integration over the C ircle in the B orel T ransform Form alism

In this section we show that the integration over the circle in eq. $(\overline{2} .4)$ for $R$ is particularly simple in the B orel representation. Starting from eqs. ( $\overline{2}$. have

W e work in the approxim ation where the two-loop coe cient ${ }^{0}$ in the beta function is neglected. Then, according to eq. ( $\overline{2} . \bar{d})$, we can replace $1=a(s)$ by $1=a+i$, where $a$ is $a(j \bar{j})=a\left(m^{2}\right)$, invert the integration order and write $s=m^{2}=\exp (i):$

$$
\begin{equation*}
r=\int_{0}^{Z_{1}} d b e{ }^{b=a} B(b) \frac{1}{2 i}^{Z} \text { id }\left(1+e^{i}\right)^{3}\left(1 \quad e^{i}\right) e^{i b}: \tag{42}
\end{equation*}
$$

The integration is easily perform ed, w ith the result

$$
\begin{align*}
r & =z_{1} \text { dbe }{ }^{b=a} B(b) \frac{12 \sin (b)}{b(b \quad 1)(b \quad 3)(b \quad 4)} \\
& =z_{1} \text { dbe }{ }^{b=a} B(b) F(b): \tag{4.3}
\end{align*}
$$

W e see that, in rst approxim ation, the e ect of going from $a(s)$ to a ( $\dot{j} \bar{s})$ by integrating over the circle is to m ultiply the B orel transform B (b) by the factor F (b). For realx, the function $F(x)$ is shown in $g '{ }^{\prime} \bar{\beta}$. It is an entire function in the whole com plex plane w th a good behaviour at in nity on the realaxis. T he factor $F$ ( $x$ ) has sim ple zeros at the location of allUV renorm alons and also ofall $\mathbb{R}$ renorm alons w ith

Figure 3: $P$ bt of the function $F(x)$.
the exception of those at $b=1$ (if any), 3 and 4 . Since, in general, the corresponding singularities are not sim ple poles, they are not elim inated, but their strength is attenuated (this point will be discussed in more detail in sect. 5.). Equation ( $\overline{4}-\bar{Z})$
 repeat the procedure by expanding in a ( ${ }^{2}$ ) instead of $a\left(m^{2}\right)$, according to eq. ( $\overline{2} \overline{2} \bar{\sim}$ ) . $T$ he resulting dependence is show in $g$. $1 / 1$ the BNP $[\overline{\text { n }}]$ and the LP form ulae.

## 5. Large $-\mathrm{N}_{\mathrm{f}}$ Evaluation of R enorm alons and their $R$ esum m ation

A s well known, the typical renorm alon diagram s of QED and QCD can be eval-
 abelian case the large $\mathrm{N}_{\mathrm{f}} \lim$ it corresponds to the large- lim it, and this is believed to be true also in the non-abelian gauge theory in spite of the fact that the beta function in this case cannot be evaluated only in term s of vacuum polarisation diagram s . The sequence of dom inant term $s$ in ${ }^{n}$ generalises the term $s$ in and ${ }^{2}$ that appear in $\widetilde{\Sigma}_{2}$ and $\widetilde{D}_{3}$ respectively. As argued in a recent paper, ref. $\left.\overline{\underline{2}} \overline{\mathrm{O}}\right]$, the determ ination of the exact behaviour of the $U V$ renorm alon series $m$ ay be very di erent from the one indicated in the large- lim it. W hile we do not know the com plete form of the leading UV renorm alon at $\mathrm{b}=1=$, we can nevertheless com pute, for orientation, the quantitative im pact of its approxim ate form at large on the determ ination of $a\left(m^{2}\right)$. From eq. (42) of ref. $[\underline{-1} 1]$ one obtains the large- expression of the contribution of the leading $U V$ renorm alon $a t b=1=$ to the $B$ orel transform $B(b)$ :

$$
\begin{equation*}
B(b)=\frac{2}{9} e^{5=3} x_{n}^{x}[7+2 n](x)^{n}=\frac{2}{9} e^{5=3} 7 \quad \frac{2 x}{1+x} \frac{1}{1+x} ; \tag{5.1}
\end{equation*}
$$

where $\mathrm{x}=\mathrm{b}$ and the factor $\mathrm{e}^{5=3}$ transform s the result from the M OM into the $\overline{M S}$ schem e. W e observe that the leading UV renorm alon is a double pole. Since in the large- lim it ${ }^{0}$ can be neglected, the corresponding expression for $R$ in the approxim ation of eq. ( 4 An pole.

W e now study the num ericale ect of including the whole renorm alon series w ith
respect to a truncated result up to the order $b^{2}$. We rst consider the im pact on $d(a)$, i.e. before the integration on the circle. In order to get the correction to $d(a)$ from the higher-order term $s$ in the $U V$ renorm alon we m ust subtract from B (b) its expansion up to $O\left(b^{2}\right)$ and perform the inverse Borel transform, eq. ( $(\underline{2}-\overline{-2})$ :

$$
\begin{equation*}
d(a)=\frac{1}{z}_{0}^{z} d x e^{x=a} B(x) \quad \frac{2}{9} e^{5=3}\left(7 \quad 9 x+11 x^{2}\right): \tag{52}
\end{equation*}
$$

For $=27=12=2: 25$ and $a=0: 12$ (or $a=027$ ) one nds $d$ 3:7 $10^{3}$ which corresponds to a $2 \%$ increase in the value of $s\left(m^{2}\right)$ at $x e d d(0: 12)=0: 155$ ( $\left.\mathrm{s}\left(\mathrm{m}^{2}\right) 0: 007\right)$.
$W$ e now repeat the sam e exercise for the function $r$, given in eq. ( $\overline{4}-\bar{z})$, obtained after integration over the circle. W e com pute the variation

$$
\begin{equation*}
r(a)=\frac{1}{2}_{0}^{z} d x e^{x=a} B(x) \quad \frac{2}{9} e^{5=3}\left(7 \quad 9 x+11 x^{2}\right) F(x): \tag{5.3}
\end{equation*}
$$

Num erically we nd $r(0: 12) \quad 6: 0 \quad 10^{3}$ which, at $x \in d r(0: 12)=0: 220$, again corresponds to $s\left(m^{2}\right) \quad 0: 007$. Thus the extra factor $F(b)$ has practically no in uence on the ect on $s\left(m^{2}\right)$ of the nearest $U V$ singularity.

In conclusion the overalle ect of the UV renorm alon singularity in this model is sm all and not much changed by the integration over the circle.

## 6. Search for $M$ ore $C$ onvergent A pproxim ants

A ssum ing that indeed there is no $\mathbb{R}$ renorm alon at $b=+1=$ one can in principle try to obtain by analytic continuation a de nition of the B oreltransform, valid on the positive realb axis up to $\mathrm{b}=+2=$, outside the radius of convergence of its expansion. W e now discuss how the analytic continuation could be im plem ented in practioe.

Starting from eq. $\left[\begin{array}{ll}-3 \\ \hline\end{array}\right.$ inverse $\mathrm{b}=\mathrm{b}(\mathrm{z}), \mathrm{z}(0)=0$ and $\mathrm{z}(1)=1$ (so that the interval from 0 to 1 in b is $m$ apped into the 0 to 1 range in $z$ ), such that the $\mathbb{R}$ singularities are $m$ apped onto the intervalbetween $z_{0}=z(2=)$ and 1 and the $U V$ singularities are pushed aw ay at

そj $\quad z_{0} \cdot$ Changing variable one obtains

$$
\begin{equation*}
d(a)=\int_{0}^{Z_{1}} d b e e^{b=a} B(b)^{Z_{1}} d z \frac{d b}{d z} e^{b(z)=a} B(b(z)): \tag{6.1}
\end{equation*}
$$

U sing the expansion

$$
\begin{equation*}
\mathrm{b}(\mathrm{z})=\mathrm{c}_{1} \mathrm{z}+\mathrm{c}_{2} \mathrm{z}^{2}+::: \tag{62}
\end{equation*}
$$

the series

$$
\begin{equation*}
B(b)=D_{1}+D_{2} b+D_{3} \frac{b^{2}}{2}+::: \tag{6.3}
\end{equation*}
$$

goes into

$$
\begin{equation*}
B(b(z))=D_{1}+D_{2} C_{1} z+\left(D_{2} C_{2}+D_{3} \frac{C_{1}^{2}}{2}\right) z^{2}+::: \tag{6.4}
\end{equation*}
$$

which is convergent up to $z=z_{0}$, while the originalb expansion was convergent only up to $b=1=$, corresponding to $z(1=)<z_{0}$. The im proved approxim ation for $d(a)$ is therefore given by

$$
\begin{array}{r}
d(a) \quad, \quad z_{z_{0}} d z \frac{d b}{d z} e^{b(z)=a} D_{1}+D_{2} C_{1} z+\left(D_{2} C_{2}+D_{3} \frac{C_{1}^{2}}{2}\right) z^{2}+::: \\
=Z_{2=}^{\#} d b e^{b=a} D_{1}+D_{2} C_{1} z(b)+\left(D_{2} C_{2}+D_{3} \frac{C_{1}^{2}}{2}\right) z(b)^{2}+::: ; \tag{6.5}
\end{array}
$$

where the fill expression of $z$ as function ofb is inserted in the integral. In this way, an in nite sequence of term $s$ is added to the bexpansion. For a small, the upper lim it of integration can be replaced w ith in nity w ithout signi cante ect.

O ne possible exam ple is given by [17]:

$$
\begin{equation*}
z(b)=\frac{p}{p \frac{p+b}{1+b}+1} \quad!\quad b(z)=\frac{4 z}{(1 \quad z)^{2}}: \tag{6.6}
\end{equation*}
$$

In this case the rst $U V$ singularity is at $z=1$, and all higher $U V$ renorm alons are on the unit circle $\dot{z} j=1 . \mathbb{R}$ renom alons are betw een $z_{0}=\left(\begin{array}{ll}\overline{3} & 1\end{array}\right)=(\overline{3}+1)$ and $z=1$. In this exam ple, $c_{1}=4=, c_{2}=8=$. O ther exam ples are

$$
\begin{equation*}
\mathrm{z}(\mathrm{~b})=\frac{\mathrm{b}}{\mathrm{k}+\mathrm{b}} \quad!\quad \mathrm{b}(\mathrm{z})=\frac{\mathrm{kz}}{(1 \mathrm{z})} \tag{6.7}
\end{equation*}
$$

with $k=1 ; 2$ or 3 . A lso in these cases the rst $\mathbb{R}$ renorm alon at $b=2=$ becom es the closest singularity to $z=0$, while the $U V$ are pushed further aw ay. H ere we have $\mathrm{C}_{1}=\mathrm{C}_{2}=\mathrm{k}=$.

Before discussing num erical applications, we observe that the present $m$ ethod relies sim ply on the position of the $\mathbb{R}$ and UV renorm alon singularities in the B orel plane and not on the nature and the strength of the singularities. W e have seen that the integration over the circle in eq. ( $\left.\overline{4}-\frac{3}{3}\right)$ does not change the position of the singularities in the b plane, but sim ply a ects their strength. Thus, we can as well consider the e ect of the accelerators on the expansions for $R^{(B N P)}$ given in eq. ( $\left.\overline{2} \overline{1} \overline{1} \bar{d}\right)$ or on the LP expression of eq. ( $\left(\underline{2} \overline{2}_{2} \bar{O}_{1}^{\prime}\right)$. For exam ple, the im proved version of eq. $(\overline{4}-\bar{Z})$ sim ply becom es

$$
\begin{equation*}
r^{\prime} \quad Z_{1} \text { dbe }{ }^{\mathrm{b}=\mathrm{a}} \mathrm{D}_{1}+\mathrm{D}_{2} \mathrm{C}_{1} \mathrm{z}(\mathrm{~b})+\left(\mathrm{D}_{2} \mathrm{C}_{2}+\mathrm{D}_{3} \frac{\mathrm{C}_{1}^{2}}{2}\right) \mathrm{z}(\mathrm{~b})^{2}+::: \mathrm{F}(\mathrm{~b}): \tag{6.8}
\end{equation*}
$$

W e now consider the follow ing num erical exercise. W e assum e that experim ents have $m$ easured $R=3: 6 . W$ e then com pute $a\left(m^{2}\right) w$ th the LP form ula as a function of the scale , and we perform the sam e calculation applying our acceleration procedures to the LP method $[\overline{4}]$. The results are shown in $g_{-1}^{-1} 1 . W$ e see that relatively large di erences in the tted value of $s\left(m^{2}\right)$ are obtained, especially at large for di erent accelerators and in com parison to the non-accelerated form ulae. W e do not see a priori com pelling reasons to prefer one or the other procedure. T he fact that a priori equivalent $m$ ethods lead to results $w$ ith a sizeable spread $m$ ust be considered as an indication of a real am biguity. Even if we only consider the m ethod of ref. [14] for the integration over the circle, it is im possible to go below an uncertainty of the order $\mathrm{s}\left(\mathrm{m}^{2}\right)$ 0:050 for in the range from 1 to 3 GeV . The am biguity becom es even larger if we extend the com parison to the form ulae with truncation in ${ }^{2} \mathrm{a}^{2}{ }^{2}$ a\{la BNP ( gǐp).

## 7. Study of M ore C onvergent A pproxim ants in a M odel

The $m$ ethod for accelerating the convergence discussed in the previous section only relies on the position of the singularities of the B orel transform and not on their nature and strength. It looks rather surprising that one can com pensate for the ect of renorm alonsw ithout actually know ing their form in detail. In this section we study a sim ple $m$ athem atical $m$ odel to clarify under which conditions the $m$ ethod can be successfiul, in the sense that it provides a better approxim ation to the true result.

Figure 4: E ect of the accelerators on the determ ination of $\mathrm{s}\left(\mathrm{m}^{2}\right)$ with the LP $m$ ethod, for $R=3: 6$. The curves $b, c$ and $d$ refer to the change of variable of eq. ( $\overline{6} \cdot \bar{T} \cdot \overline{1})$, while e refers to eq. $(\overline{6} \cdot \bar{\sigma})$.

Figure 5: A s in Fig. ${ }_{-1}^{1} \overline{4}$, for the BN P m ethod.

W e consider as a m odel the case where the B orel transform is exactly speci ed by

$$
\begin{aligned}
& B_{\text {true }}(b)=1+D_{2} b+D_{3} \frac{b^{2}}{2}+{ }_{n=3}^{x^{A}} @_{n}^{0} n+1_{A}^{1}(b)^{n} \\
& =1+D_{2} \mathrm{~b}+\mathrm{D}_{3} \frac{\mathrm{~b}^{2}}{2}+\frac{"}{(1+\mathrm{b})} \quad 1+\mathrm{b} \frac{(+1)}{2}(\mathrm{~b})^{2}:(7.1)
\end{aligned}
$$

T he added sum stands for the higher-order contribution that could arise from a leading UV renom alon at $b=1=w$ ith a degree of singularity speci ed by and a xed overall strength given by . We will take $=1$ in the follow ing discussion. It is convenient to re-express eq. (IT. $\overline{1}$ ) in term sof $x=\mathrm{b}$ :

$$
\begin{equation*}
B_{\text {true }}(x)=1+\bar{D}_{2} x+\bar{D}_{3} \frac{x^{2}}{2}+\frac{1}{(1+x)} \quad 1+x \quad \frac{(+1)}{2} x^{2}: \tag{72}
\end{equation*}
$$

where $\bar{D}_{2}=D_{2}=$ and $\bar{D}_{3}=D_{3}={ }^{2}$. Sim ilarly we can introduce $B_{\text {pert }}(x)$ and $B_{\text {accel }}(x)$, the perturbative Borel functions without and with acceleration, respectively:

$$
\begin{gather*}
\mathrm{B}_{\text {pert }}(\mathrm{x})=1+\overline{\mathrm{D}}_{2} \mathrm{x}+\overline{\mathrm{D}}_{3} \frac{\mathrm{x}^{2}}{2}  \tag{7.3}\\
\mathrm{~B}_{\text {accel }}(\mathrm{x})=1+\overline{\mathrm{D}}_{2} \overline{\mathrm{c}}_{1} \mathrm{z}(\mathrm{x})+\overline{\mathrm{D}}_{2} \overline{\mathrm{c}}_{2}+\overline{\mathrm{D}}_{3} \frac{\overline{\mathrm{C}}_{1}^{2}}{2} \mathrm{z}(\mathrm{x})^{2} ; \tag{7.4}
\end{gather*}
$$

where $\overline{\mathrm{c}}_{1 ; 2}=\mathrm{C}_{1 ; 2}$. In all cases the corresponding d function, $\mathrm{d}_{\text {true }}, \mathrm{d}_{\text {pert }}$ and $d_{\mathrm{accee}}$ is given by

$$
\begin{equation*}
d(a)=\int_{0}^{Z_{1}} d x e^{x=a^{a}} B(x): \tag{7.5}
\end{equation*}
$$

W e consider the ratio

$$
\begin{equation*}
H=\frac{d_{\text {true }}}{d_{\text {true }}} \quad d_{\text {accel }} d_{\text {pert }}=1 \quad \bar{D}_{2} I_{2}(a) \quad \bar{D}_{3} I_{3}(a) ; \tag{7.6}
\end{equation*}
$$

where the quantities $I_{2 ; 3}$ are given by

$$
\begin{align*}
& I_{2}(a)=\frac{1}{I_{0}(a)}{ }_{0}^{z} d x e^{x=a} \bar{C}_{1} z(x)+\bar{C}_{2} z(x)^{2} x  \tag{7.7}\\
& I_{3}(a)=\frac{1}{2} \frac{1}{I_{0}(a)}{ }_{0} d x e^{x=a} \bar{c}_{1}^{2} z(x)^{2} x^{2} \tag{7.8}
\end{align*}
$$

and

$$
\begin{equation*}
I_{0}(a)=z_{0}^{z_{1}} d x e^{x=a} \frac{1}{(1+x)} \quad 1+x \frac{(+1)}{2} x^{2}: \tag{7.9}
\end{equation*}
$$

C learly, $j$ j $<1$ is the condition for the acceleration $m$ ethod to be successfiul. In particular for $H=0 d_{\text {true }}$ and $d_{a c c e l}$ coincide. For each value of $a$ and, in a given $m$ odel speci ed by $z(x)$ and the corresponding coe cients ${ }_{q} ; 2$, the condition $H=0$ is satis ed on a straight line in the plane $\overline{\mathrm{D}}_{2} ; \overline{\mathrm{D}}_{3}$, while the inequality $\mathrm{f} \boldsymbol{j} \mathrm{j}<1$ is satis ed in a band de ned by two straight lines parallel to the $H=0$ line. In ${ }_{9}{ }_{9}^{\prime}$ we plot the lines $H=0$ for $a=0.27$ for $x e d$ and $z(x)$ given by eq. ' $(\bar{\sigma} \cdot \overline{6})$ (case labelled by 0 ), or by eq. ( $\left.\overline{6} \bar{\sigma}_{1}\right)$ w th $k=1$ or 2 (cases 1 and 2 ). The values of in

Figure 6: Lines corresponding to $H=0$ for the $m$ ethod $\backslash 0 "$ (solid), $\backslash 1 "$ (dashed) and $\backslash 2$ " (dotted) for $=0: 5$. The circle corresponds to expansion of $1=(1+x)$.
gsser negative slopes. The lines tend to cross each other in a region of the plane not far from the point $\bar{D}_{2}=, \bar{D}_{3}=(+1)$, i.e. the values that correspond to the rst few term s of the expansion of the asym ptotic function $1=(1+x)$. The region where

Figure 7: A s in Fig.' 1 - $\overline{-1}$, for $=1$.

Figure 8: A s in Fig.i' $\overline{-1}$, for $=2$.
the lines cross is m ore shanply de ned if is sm all, i.e. if the asym ptotic function is not too singular. In gs. 9 and 1 .

Figure 9: Bands corresponding to $f i j<1$ for the $m$ ethod $\backslash 0 "$ (solid), \1" (dashed) for $=0: 5$.

The conclusion is that the $m$ ethod for accelerating the convergence w onks wellonly if the coe cients $\overline{\mathrm{D}}_{2} ; \overline{\mathrm{D}}_{3}$ resem ble those of the asym ptotic series, in other words if the known term $s$ in the expansion are su ciently representative of the asym ptotic series. In particular we see that it is very unlikely to get an im provem ent if the coe cients $\overline{\mathrm{D}}_{2}$ and $\overline{\mathrm{D}}_{3}$ are of the sam e sign, as is unfortunately the case for the series of interest for us (see eq.6).

From a di erent point of view we now consider the sim ple function B (b) given by

$$
\begin{equation*}
B(b)=\frac{1}{(1+b)} \tag{7.10}
\end{equation*}
$$

Figure 10: A s in Fig.' ${ }_{-1}$, for $=1$.
and we plot the relation of the exact result

$$
\begin{equation*}
d(a)=\int_{0}^{z_{1}} d x e^{x=a} B(x) \tag{7.11}
\end{equation*}
$$

$w$ ith its accelerated or non-accelerated series approxim ants, as a function of a and of the order of the expansion. T he results obtained for the accelerating function $z$ (b) given in eq. ( $\overline{6} . \bar{W}$ ) (the case labeled by 0 ) and $=1 ; 2$ are shown in gs. 1

Figure 11: E ect of the resum $m$ ation technique described in the text, for a function with Borel transform $B(b)=1=(1+\mathrm{b}) ;=1$
se that when, as in this case, the coe cients of the expansion coincide with their asym ptotic form the accelerated form ulae provide a much better approxim ation to the true result, $m$ ore so if the singularity is weaker (i.e. is sm aller). The nonaccelerated form ulae are only good for sm all enough a. The physically interesting case of a 0.27 appears to be at the lim it of the range where the non-accelerated form ulae are acceptable.

Figure 12: E ect of the resum $m$ ation technique described in the text, for a function with B orel transform B (b) $=1=(1+\mathrm{b})$; $=2$

## 8. C onclusion

The determ ination of $s\left(m^{2}\right)$ or $s\left(m_{z}^{2}\right)$ from decay is nom inally very precise and the experim ental errors are extrem ely sm all at LEP. Certainly the dom inant am biguly is at present the theoretical error. The nom inal precision is large because in the $m$ assless lim it no explicit $1=m^{2}$ corrective term $s$ are present in the operator expansion. But it has becom e clear by now that one cannot sensibly talk of powersuppressed corrections ifthe am biguities in the leading term are not under control $W$ e think that there is no real theorem that prevents non-perturbative corrections in the coe cient function of the leading term in the operator expansion at the level of
${ }^{2}=m^{2}$. Equivalently, there could be an $\mathbb{R}$ renorm alon singularity at $b=+1=$, which w ould create an irreducible (being located on the integration path) am biguity of order
${ }^{2}=\mathrm{m}^{2}$. In all-order perturbative evaluations of the singularity pattem in the B orel plane the $\mathbb{R}$ singularity at $\mathrm{b}=+1=$ is probably absent, a result consistent w th the idea that all irreducible am biguities can be reabsorbed in condensates. Even if the $\mathbb{R}$ renorm alon singularity at $\mathrm{b}=+1=$ is indeed absent, the radius of convergence of the expansion is lim ited by the leading $U V$ renorm alon singularity at $b=1=$. If this disease is not cured or cannot be cured the resulting am biguity is still of order
${ }^{2}=m^{2}$. In principle the problem could be solved if the exact nature and strength of the singularity was known, by sim ply taking its e ect into account in the evaluation of $s\left(m^{2}\right)$, along the way indicated in section 5 in the case of the estim ate of the singularity in the unrealistic lim it of large. But the exact determ ination of the singularity appears to be beyond the soope of presently known m ethods. In the actual case where the UV renorm alon singularity $a t b=1=$ is not speci ed, one can still try, in principle, to bypass the problem by a transform ation of variables that pushes the leading UV singularity to a larger distance from the origin than the rst $\mathbb{R}$ renom alon singularity at $b=+2=$. Expanding in the new variable is equivalent to add a speci ed in nite sequel of term $s$ to the original expansion. The convergence of the series should be im proved by these accelerators of convergence and the ambiguity decreased. $W$ e have studied the quantitative e ect of im plem enting a num ber of such accelerators $w$ th di erent choices of the renom alisation scale. A n indication of the size of the am biguities on $s\left(\mathrm{~m}^{2}\right)$ is obtained from the spread of the results for di erent starting form ulae (e.g. with a (s) taken in the integration over the circle in its renorm alisation group im proved form or in a xed order truncated
expansion), di erent accelerator functions and di erent choioes of the renorm alisation scale. The di erence between the resum $m$ ed or truncated expression for a ( $s$ ) on the circle are expecially large at sm all values of , while the variations induced by the di erent accelerators are expecially pronounced at large values of . The relative stability of the unaccelareted result of ref. accidental in that the accelerated form ulae based on it are $m$ uch less stable at large - It was argued in ref. $1-\overline{1}-1$ that if one expands in $s\left({ }^{2}\right)$ instead of expanding in $s\left(m^{2}\right)$ the scale dependence of the UV renorm alon correction becom es of order $\left({ }^{2}=m^{2}\right)\left(m^{2}={ }^{2}\right)^{2}$. C an then one be safe if is chosen su ciently large? C learly in the true result the sum of the perturbative term $s$ plus the rem ainder $m$ ust be scale independent. W hen is changed, the num ber of term $s$ to be added before the series becom es asym ptotic changes and must com pensate for the di erence. T he increased sensitivity of the accelerated form ulae at large is not encouraging for invoking that large is safer. Alltogether, from g. 4 we nd it di cult to im agine that the theoretical error on the strong coupling can be taken sm aller then, say, $\mathrm{s}\left(\mathrm{m}^{2}\right) \quad 0: 050$ (which approxim ately corresponds to $\mathrm{s}\left(\mathrm{m}_{\mathrm{z}}^{2}\right) \quad 0: 005$ ).
$T$ he accelerator $m$ ethod is based on the $m$ ere know ledge of the position of the singularity and not on its precise form. C learly such a m ethod can only work if the known term s of the expansion carry enough inform ation on the asym ptotic form of the series. $W$ e have quantitatively con $m$ ed this statem ent by studying the problem on a sim ple $m$ athem aticalm odelw here the true result is know $n$. The perform ance of di erent accelerators is studied as a function of the coe cients of the rst few term $s$. These results indicate that there is little hope of im proving the am biguity from the leading UV renorm alon because the rst few coe cients of the actualexpansion show no evidence for the asym ptotic behaviour, in particular no sign altemance. This last argum ent (as well as the one on the dependence of the UV renorm alon) can be interpreted in di erent ways. If one is a great optim ist, he can argue that the series does not resemble at all to the renom alon asym ptotics, hence the norm alisation of the renom alon term is very sm all (as is the case for the explicit form of the singularity obtained in the large $\mathrm{N}_{\mathrm{f}} \lim$ it). O r , if one is m ore cautious, as one should be in estim ating errors, he can say that since the known term $s$ do not show sign of asym ptotia, they are dom inated by subasym ptotic e ects and cannot be used to estim ate the rem ainder. In this spirit we do not propose the accelerators as a better way to determ ine the true result but sim ply as a criterium to evaluate the theoretical
error. In fact, while all accelerators tend to increase the resulting value of $s$, the am ount of the upw ard shift is sizeably di erent for di erent accelerators.

In order to bypass allpossible ob jections one should be able to $t$ at the sam e tim e $s\left(m^{2}\right)$ and $C_{2}$, the coe cient of $1=m^{2}$ corrections to $R$. N ote that in the ALEP H m om ent analysis $\left[{ }_{[15}^{\top}\right] \mathrm{C}_{2}$ is xed to zero while the coe cients of som e higher-dim ension operators are tted. This is not very relevant to the m ain issue. If $\mathrm{C}_{2}$ is not xed it is found that the sensitivity to $s\left(m^{2}\right)$ is $m$ uch reduced. In an interesting paper $N$ arison [2]-9] attem pted to put an upperbound on $\mathrm{C}_{2}$ from the data on $\mathrm{e}^{+} \mathrm{e}$ ! hadrons. T his is an im portant issue that would deserve further study. O ur interpretation of the

 too much on the so called optim isation procedure. Indeed, som ething that should be a constant in a dum $m y$ variable tums out to be a steep parabola. The value at the tip is taken, w ith a sm all error, as the best estim ate because of the vanishing of the derivative at that point, instead of considering the span of the results in a priori reasonable range for the irrelevant param eter. In a recent paper [ī̄0] ] an estim ate of $\mathrm{C}_{2}$ from A rgus data on hadronic decay was obtained and the results are com patible $w$ th $\mathrm{J}_{2} \mathrm{j}<(500 \mathrm{MeV})^{2}$.

W e ignored here other possible sources of error beyond those arising from higher orders in perturbation theory. These inchude errors from the freezing $m$ echanism for $s$, errors from the translation of $s\left(m^{2}\right)$ in term $s$ of $s\left(m_{z}^{2}\right)$, from the region of the circle integration near the positive real axis and so on. These errors are presum ably sm aller $[\underset{-1}{-1}]$ than our current estim ate of the error from higher order term $s$ in the perturbative espansion. Taking all the other uncertainties into account we end up w ith a total theoretical error around $s\left(m_{z}^{2}\right)$ 0:006. A s a result, in spite of the fact that our estim ate of the error is larger than usually quoted, the determ ination of $s\left(m_{z}^{2}\right)$ from rem ains one of the best determ inations of the strong coupling constant.
