We consider the effects of quark-binding on the angular distribution and polarization characteristics of the inclusive decays $\Lambda_b \rightarrow X_s \gamma$ and $\Lambda_b \rightarrow X_c l \bar{\nu}_l$ ($l = e, \tau$), using the methods of heavy quark effective theory.

1 Introduction

This is a summary of two papers^{1,2} in which we have considered the effects of quark-binding on the decays $b \rightarrow s \gamma$ and $b \rightarrow q l \bar{\nu}_l$, when the b -quark is embedded in a polarized Λ_b -baryon.

In the free-quark model (FQM), the decay $\vec{b} \rightarrow s \gamma$ of a polarized b -quark produces a monochromatic photon whose angular distribution relative to the b -spin direction is

$$\frac{d\Gamma}{d\cos\theta} \sim 1 - \frac{1-\xi}{1+\xi} \cos\theta, \quad (1a)$$

where $\xi = m_s^2/m_b^2$. The polarization of the photon is

$$P_\gamma = -\frac{1-\xi}{1+\xi}. \quad (1b)$$

Likewise, in the decay $\vec{b} \rightarrow q l \bar{\nu}_l$ the angular distribution of the lepton relative to the b -spin is

$$\frac{d\Gamma}{d\cos\theta} \sim 1 - \frac{1}{3} f\left(\frac{m_q^2}{m_b^2}, \frac{m_l^2}{m_b^2}\right) \cos\theta, \quad (2)$$

where $f(m_q^2/m_b^2, m_l^2/m_b^2)$ is a calculable function equal to unity when m_q and m_l are zero. The lepton in the final state has a characteristic polarization \vec{P} , with a longitudinal component P_L and a transverse component $P_T \sim m_l/m_b$ in the decay plane. Our objective is to analyse how the free-quark characteristics (1) and (2) are modified when the b -quark is a constituent of a polarized Λ_b -baryon.

2 The decay $\Lambda_b \rightarrow X_s \gamma$

The decay $\vec{\Lambda}_b \rightarrow X_s \gamma$ is governed by the effective Hamiltonian

$$H_{\text{eff}} = \frac{-4G_F}{\sqrt{2}} \frac{e}{16\pi^2} V_{tb} V_{ts}^* c_\gamma(m_b) \times \bar{s} \sigma^{\mu\nu} (m_b P_R + m_s P_L) b F_{\mu\nu}, \quad (3)$$

which produces a distribution ($y = 2E_\gamma/m_b$)

$$\frac{d\Gamma}{dy d\cos\theta} = \frac{\alpha G_F^2 m_b^2}{2^7 \pi^5} |V_{tb} V_{ts}^*|^2 |c_\gamma(m_b)|^2 y \text{Im} T(y, \cos\theta), \quad (4)$$

where the function $T(y, \cos\theta)$, calculated to order $1/m_b^2$ in the operator product expansion (OPE), is¹

$$T(y, \cos\theta) = 2y^2 m_b^3 \frac{1}{(y - y_0 - i\epsilon)} \times \{[1 + h(y)K](1 + \xi) - \cos\theta [1 + \epsilon_b + h(y)K](1 - \xi)\}, \quad (5)$$

with

$$h(y) = \frac{5}{3} - \frac{7}{3} \frac{y}{(y - y_0 - i\epsilon)} + \frac{2}{3} \frac{y^2}{(y - y_0 - i\epsilon)^2}. \quad (6)$$

The parameters K and ϵ_b are defined by

$$K = -\langle \Lambda_b | \bar{h}_v \frac{(iD)^2}{2m_b^2} h_v | \Lambda_b \rangle, \quad (7)$$

$$(1 + \epsilon_b) s^\mu = \langle \Lambda_b(s) | \bar{b} \gamma^\mu \gamma^5 b | \Lambda_b(s) \rangle, \quad (8)$$

and express the effects of quark-binding. The angular distribution of the decay photon is

$$\frac{d\Gamma}{d\cos\theta} \sim 1 - K - (1 + \epsilon_b - K) \frac{1-\xi}{1+\xi} \cos\theta, \quad (9a)$$

*Talk presented by L. M. Sehgal at the *International Europhysics Conference on High Energy Physics*, Brussels, 27 July–2 August, 1995. To appear in the proceedings.

Table 1: Angular distribution of leptons in the inclusive decay $\bar{\Lambda}_b \rightarrow X_q l \bar{\nu}_l$, including quark-binding effects.

Decay	$d\Gamma/\cos\theta$ (arbitrary unit)
$\Lambda_b \rightarrow X_u e \bar{\nu}_e$	$(1 - K) - \frac{1}{3}(1 + \epsilon_b - K) \cos\theta$
$\Lambda_b \rightarrow X_c e \bar{\nu}_e$	$(1 - K) - 0.25(1 + \epsilon_b - K) \cos\theta$
$\Lambda_b \rightarrow X_u \tau \bar{\nu}_\tau$	$(1 - K) - 0.45(1 + \epsilon_b - 1.8 K) \cos\theta$
$\Lambda_b \rightarrow X_c \tau \bar{\nu}_\tau$	$(1 - K) - 0.34(1 + \epsilon_b - 2.7 K) \cos\theta$

and the photon polarization, as a function of direction, is

$$P_\gamma(\cos\theta) = -\frac{1 - \xi - \alpha(1 + \xi) \cos\theta}{1 + \xi - \alpha(1 - \xi) \cos\theta}, \quad (9b)$$

with $\alpha = (1 + \epsilon_b - K)/(1 - K)$. The results (9a) and (9b), which are the QCD-improvements of the results (1a) and (1b), are represented in Figs. 1 and 2, for $K = 0.01$ and $\epsilon_b = -\frac{2}{3}K$.

3 The decay $\Lambda_b \rightarrow X_q l \bar{\nu}_l$

In the case of the decay $\bar{\Lambda}_b \rightarrow X_q l \bar{\nu}_l$ ($q = u$ or c , $l = e$ or τ), the differential decay rate has the form $d\Gamma \sim L_{\mu\nu} H^{\mu\nu}$, where the hadronic tensor is

$$H_{\mu\nu} = \frac{1}{\pi} \text{Im} i \int d^4x e^{-iq \cdot x} \langle \Lambda_b | T \{ j_\mu^\dagger(x) j_\nu(0) \} | \Lambda_b \rangle, \quad (10)$$

with $j_\mu = V_{qb} \bar{q} \gamma_\mu (1 - \gamma_5) b$. This tensor may be expanded in terms of 5 structure functions $T_1 \dots T_5$, for unpolarized Λ_b , and 9 additional functions $S_1 \dots S_9$, for polarized Λ_b . Using OPE to order $1/m_b^2$, it is possible to determine all of these structure functions in terms of the parameters K and ϵ_b .

The inclusive distribution of the lepton as a function of energy and angle has the form² ($y = 2E_l/m_b$)

$$\frac{d\Gamma}{dy d\cos\theta} \sim [A_0 + A_1 K + \{B_0(1 + \epsilon_b) + B_1 K\} \cos\theta], \quad (11)$$

where $A_{0,1}$ and $B_{0,1}$ are calculable functions of y . In the limiting case $\Lambda_b \rightarrow X_u e \bar{\nu}_e$, with $m_u = m_e = 0$, the functions A_0, B_0 have a form familiar from μ -decay:

$$A_0 = (3 - 2y)y^2, \quad B_0 = (1 - 2y)y^2. \quad (12)$$

Table 1 lists the inclusive distribution $d\Gamma/d\cos\theta$, integrated over y , for the various inclusive processes $\bar{\Lambda}_b \rightarrow X_q l \bar{\nu}_l$. A further observable of interest is the τ -

Figure 1: The fractional intensity I of photons in the forward cone $\cos\theta_0 \leq \cos\theta \leq 1$.

Figure 2: The photon polarization P_γ in the inclusive Λ_b decay as a function of the photon direction with $K = 0.01$ and $\epsilon_b = -\frac{2}{3}K$.

polarization in the decay $\Lambda_b \rightarrow X_c \tau \bar{\nu}_\tau$. The τ has a longitudinal polarization component P_L as well as a transverse component P_T in the decay plane. These are shown in Figs. 3 and 4, as functions of the lepton energy. The average values are $\langle P_L \rangle \approx -0.70$ and $\langle P_T \rangle \approx 0.19$. The quark-binding effects are generally small, except in the region of large y , where the OPE breaks down, and a “smoothing” procedure is necessary. When the Λ_b is polarized, there is an interesting correlation of \vec{s}_τ with \vec{s}_{Λ_b} . In particular, the τ -lepton can have a small polarization component P_\perp perpendicular to the decay plane, which is proportional to K , and hence a pure manifestation of the “Fermi motion” of the b -quark in the hadron.
