

# STATUS OF HIGH ENERGY FORWARD ELASTIC SCATTERING

Kyoungsik Kang<sup>1</sup> and Sung Ku Kim<sup>2</sup>

Department of Physics, Brown University, Providence, RI 02912, USA

## Abstract

We present the results of fitting all data for  $p\bar{p}$  and  $p\bar{p}$  scattering at  $\sqrt{s} = 9.7 \text{ GeV}$  and up to the collider energy with various analytic parametrizations of the elastic forward scattering amplitudes based on the derivative dispersion relation. It is found that the model containing the Pomeron and Reggeon terms with 8 parameters has the most preferred  $\chi^2/\text{d.o.f.} = 1.3$ , while the Donnachie and Landshoff model with 5 parameters has  $\chi^2/\text{d.o.f.} = 2.16$  for a data set of 111 experimental points. The current data however make no clear preference between the 'ns and 'n<sup>2</sup>s type Pomerons.

## I. Complete Survey of Experiments

It is crucial to select as complete a set of data as possible. No experimental group is to be left out, nor any errors to be reduced to account for paucity of higher energy results. This type of analysis has been done on different sets of data depending only on the lowest value of  $\sqrt{s}$  allowed: 9.7 GeV vs. 5 GeV<sup>1)</sup>. This report deals exclusively with the data set containing 111 experimental points for the lowest value of  $\sqrt{s} = 9.7 \text{ GeV}$  distributed as follows: 58 values of  $t$ , 22 for  $p\bar{p}$  and 36 for  $p\bar{p}$ , and 53 values of  $t$ , 12 for  $p\bar{p}$  and 41 for  $p\bar{p}$ . We included the new data from UA4.2<sup>2)</sup>, CDF<sup>3)</sup>, and E710<sup>4)</sup>. Because the majority of precise data is at lower energies ( $\sqrt{s} < 63 \text{ GeV}$ ), we should expect a detailed Regge parametrization. Also because the newest higher energy experimental data are closer to standard theoretical expectations, we should expect several theoretical models to do well.

## II. Models for the Elastic Forward Scattering Amplitude

Though we have in principle the exact theory of the strong interactions, QCD, which can describe, based on the perturbative calculation, the hadron interactions at short distances, the interactions at large distance, i.e., near forward scattering can not reliably be calculated with the perturbative QCD. On the other hand, phenomenological models for high energy scattering based on general principles such as unitarity, analyticity and crossing-symmetry, have proven to be successful in understanding or predicting the high-energy behavior of the hadronic scattering amplitude<sup>5)</sup>. Two such examples are analytic amplitude models as solutions of the Derivative Dispersion Relation (DDR)<sup>6)</sup> derived from the Soper-Merfeld-Watson-Regge representation (SWR) and comprehensive eikonal models<sup>7)</sup>, based on QFT expectations or the parton model.

<sup>1</sup>Support in part by the USDOE contract DE-FG 02-91ER 40688-Task A

<sup>2</sup>Permanent address: Department of Physics, Ewha Womans University, Seoul 1120-750, Korea and Supported in part by the Korea Science and Engineering Foundation through Center for Theoretical Physics at Seoul National University, SNU-Brown Exchange Program and the Ministry of Education through BSRI-94-2427.

In this report we will concentrate on the analytic amplitude models derived from DDR. The crossing-even and odd amplitudes  $F$  for  $pp$ ,  $pp$  scattering are defined by

$$F = \frac{1}{2} (F_{pp} - F_{\bar{p}\bar{p}}) \quad (1)$$

where the normalization condition is given by

$$T = \frac{1}{S} \text{Im } F(s; t=0) \quad (2)$$

to satisfy the optical theorem.

A Regge pole at  $J = R(t)$  in the complex  $j$ -plane gives

$$F_+^k(s; t) = C_+^k(t) [i \cot(\frac{k}{2} + k(t))] s_+^{k(t)} \quad \text{if } C \text{ is even} \quad (3)$$

$$F^k(s; t) = C^k(t) [i + \tan(\frac{k}{2} + k(t))] s^{k(t)} \quad \text{if } C \text{ is odd} \quad (4)$$

If the Regge pole is Exchange-Degenerate, we have

$$C_+^k = C^k; \quad k_+ = k \quad (5)$$

Clearly Regge pole model such as the Donnachie-Landshoff model satisfies DDRs. A small  $(0) - 1 = 0.08$  is consistent with the slow increase of  $T(s)^8$ , but would eventually be in conflict with the unitary condition, i.e., the Froissart bound  $T(s) \leq C (\ln s)^2$ . A fully unitary theory must satisfy multiparticle unitarity in both  $s$ - and  $t$ -channels. Also the Pomeranchuk theorem, i.e.,  $\frac{pp}{T}(s) = \frac{pp}{T}(s) + 1$  as  $s \rightarrow 1$ , can be proven rigorously only if total cross-sections increase with energy<sup>9</sup>.

If the total cross-section increases with energy, the leading  $j$ -plane singularity of  $F_+$  is at  $j = 1$  in the forward direction. One can then write an analytic parametrization for the contribution of this asymptotic part from the derivative dispersion relation

$$F_+^{P2}(s; o) = i s [A_+ + B_+ (\ln \frac{s}{s_+} - \frac{i\pi}{2})^2] \quad (6)$$

if  $T(s)$  behaves like  $(\ln s)^2$  at high energies and

$$F_+^{P1}(s; o) = i s [A_+ + B_+ (\ln \frac{s}{s_+} - \frac{i\pi}{2})] \quad (7)$$

if  $T$  increase with energy as  $\ln s$ . On the other hand, the odd-signatured counter part of the Pomeranchuk can also be constructed by that the difference  $= \frac{pp}{T} - \frac{pp}{T}$  does not necessarily vanish asymptotically. This implies the leading  $j$ -plane singularity of  $F$  is also at  $j = 1$  in the forward direction and one can get the maximal odderon amplitude from the DDR

$$F^o(s; o) = s [A + B (\ln \frac{s}{s_+} - \frac{i\pi}{2})^2] \quad \text{if } \ln s \quad (8)$$

$$F^o(s; o) = s [A + B (\ln \frac{s}{s_+} - \frac{i\pi}{2})] \quad \text{if } \ln s \text{ const:} \quad (9)$$

Equation (8) is the maximal odderon amplitude if  $F_+$  satisfies Eq.(6) because  $(\ln s)^{-2}$  asymptotically if the cross-section increase as  $(\ln s)^{-2}$ .

The asymptotic analytic amplitude model can then be constructed in various form of

$$F_+ = F_+^{P_1}(s; o) + \sum_{k=1}^X F_+^{(k)}(s; o) \quad (10)$$

$$F_- = F_-^0(s; o) + \sum_{k=1}^X F_-^{(k)}(s; o) \quad (11)$$

where  $F^{(k)}$  represents the Regge amplitudes.

### III. Comparison with Experiment

We now present the results of our comprehensive fits to 111 high energy data points by theoretical models with and without the Odderon term along with the predictions at the LHC energy.

Depending on the choices of various terms from the expressions (10) and (11), we studied the following 10 models:

- (a) Model A 1: The Block-Kang-Willem model<sup>1)</sup>,  $P_1 + RND_+ + RND_-$ , where  $P_1$  is the 'ns-type Pomeron term and  $RND_\pm$  represent non-degenerate Regge terms. Since  $A_+ = B_+$ , 'ns<sub>+</sub> is fixed, this model has 6 (= 3 + 2 + 2 - 1) free parameters.
- (b) Model A 2: Modification of Model A 1 by replacing  $P_1$  by the '(ns)<sup>2</sup>-type Pomeron term,  $P_2 + RND_+ + RND_-$  with 7 parameters.
- (c) Model A 3:  $P_2 + RD$  with 5 parameters, where  $RD$  is the exchange degenerate Regge term.
- (d) Model B 1:  $P_1 + RD + RND_+ + RND_-$  with 8 free parameters.
- (e) Model B 2: Modification of Model B 1 by replacing  $P_1$  by  $P_2$ , i.e.,  $P_2 + RD + RND_+ + RND_-$  with 9 free parameters.
- (f) Model E 1: The maximal Odderon model,  $P_2 + O + RD + RND_+ + RND_-$  with 12 free parameters.
- (g) Model E 2: The maximal Odderon model with one exchange degenerate Regge term,  $P_2 + O + RD$  with 8 parameters.
- (h) Model E 3: The maximal Odderon model without the exchange degenerate Regge term,  $P_2 + O + RND_+ + RND_-$  with 10 parameters.
- (i) Model F 1: The model with the bare Pomeron plus the nondegenerate Regge terms,

$$\begin{aligned} C_1 s^{A_1} + C_2 s^{A_2} + C_3 s^{A_3} &\quad \text{for } p\bar{p}, \\ C_1 s^{A_1} + C_2 s^{A_2} + C_3 s^{A_3} &\quad \text{for } pp. \end{aligned}$$

This model has 6 parameters.

- (j) Model F 2: The Donnachie-Landshoff (DL) Model<sup>8)</sup>, which is a modification of Model F 1 by setting  $A_2 = A_3$ . This model is similar to Model A 3 and has 5 free parameters.

The results of the fits for the parameters are given below in Table along with the predictions of  $\sigma_T$  and  $\sigma_T^2$  at LHC ( $\sqrt{s} = 14$  TeV). Fig. 1 shows fits to Model B 1 and Fig. 2 exhibits the fits to Model F 2, the Donnachie-Landshoff Regge model.

### IV. Conclusions

- (a) Models B 1,  $P_1 + RD + RND_-$ , and Model B 2,  $P_2 + RD + RND_-$ , have the most preferred fits with  $\chi^2/\text{d.o.f.} = 1.3$  to the data for  $\sqrt{s} = 9.7$  GeV. There are, however, no significant differences between the two models: the current data are consistent with either 'ns or 'n's increase of  $\sigma_T$ .

- (b) All of the models considered above based on the asymptotic analytic amplitudes reproduce the data more or less equally well, i.e.,  $\chi^2/\text{d.o.f.} = 1.3 - 1.45$ , considering the quality of the data from different experiments. In particular, the maximal Odderon models E 1 and E 2 give comparable fits as those of Models B 1 and B 2 so that there seems to be little support for the

O dderon in the current data.

(c) The Regge model F2 has relatively high  $\chi^2/\text{d.o.f}$  but the Model F1, which is a modified version of F2 by relaxing the exchange degeneracy assumption, has significantly improved and comparable  $\chi^2/\text{d.o.f}$  value as those of Model A1 or A2.

(d) For the asymptotic behavior of  $T(s)$  extracted from this study and a comparison with the phenomenological fits made in the 1994 Review of Particle Properties<sup>10)</sup>, see Kang's talk<sup>11)</sup>.

(e) We denote that the coefficient C's of exchange degenerate Regge terms have values with huge errors in Model B1 and B2: 6042.5 2261.6 and 8857.2 7424.6, respectively. Thus we should need more low energy data by lowering the cut-off below 9.7 GeV, if their errors are to be reduced and improved.

One of us (SKK) would like to thank Brown University for warm hospitality extended to him during his sabbatical stay during the academic year 1994-95.
