For strong enough Yukawa coupling the electroweak standard model fermion finds it energetically advantageous to transform itself into a bound state in the hedgehog background of Higgs field in semiclassical approximation. By considering the bound states give the masses for lepton and quark, we found that all the strongly Yukawa coupling constants tend to an unitary constant. On the other hand, the masses of W and Z produced by the hedgehog Higgs field keep almost no change.

P A C S n u m b e r (s) : 12.50.Ch, 12.15.Ff, 11.10.St

The standard model of the electroweak interaction [1] has received a great deal of phenomenological support. The gauge boson and fermion structure of the model has been confirmed to a high degree of accuracy, while, there is very little phenomenological support for the Higgs sector of the theory. The most difficult part to understand of this theory is the Yukawa sector. It contains a large number of free parameters that must be adjusted by hand to obtain a realistic spectrum of particles and mixings. Recently, it is reported that the top quark mass is much bigger than the masses of other lepton and quark [2]. There is a large mass hierarchy among three generation fermions. These features of the standard electroweak theory may be understood by use of some of the successful ideas of this theory, or by entirely new ideas.

The basic dynamic degrees of freedom in the electroweak theory are the two-component Weyl fields with definite helicities. The gauge interactions conserve helicity and do not mediate between the system of the lefthanded and the one of the righthanded fermions. The only bridge between those two is provided by the hypothetical scalar Higgs boson which couples to the various fermions with a strength proportional to their masses. The lepton and quark in standard model are massless before the spontaneous symmetry breaking (SSB) and their masses are produced by the Yukawa coupling after the SSB. The standard picture in the model with SSB involves a vacuum expectation value (VEV) for the Higgs fields which are constant over the whole space. The fermion mass values are given by introducing Yukawa coupling constants, and the masses are proportional to the Yukawa coupling constants. On the other hand, it is expected that the presence of fermion with strong coupling to the Higgs field can modify the standard picture. As the Yukawa coupling increases the Higgs field around a fermion tends to go over from a uniform spatial configuration to a hedgehog configuration [3]. The uniform configuration leads to a fermion mass which increases linearly with the coupling constant while the hedgehog configuration gives a decreasing mass.

The existence of two possible configurations means that one can get the same mass value in both weakly Yukawa coupling phase and strongly Yukawa coupling phase. For describing the mass spectrum of lepton and quark in the weakly coupling phase, we must introduce nine hierarchical Yukawa coupling constants which vary about from 10^{-6} to 1.0. In this letter, alternatively, we shall consider the consequences of strongly Yukawa coupling phase to take the place of the standard picture for fermion sector in Weinberg-Salam model. We found that in the strong coupling phase all the Yukawa coupling constants tend to an unitary constant and the hierarchy of Yukawa coupling constants is absent. Furthermore, this scheme gives a hint to unify the all Yukawa coupling constants.

The strongly coupled Higgs fermion sector of the standard model has been investigated in Ref. 3. In those works they exploit the analogy between the strongly Yukawa coupling theory and the chiral linear model. They follow the papers of Ref. 4 which work in the context of strong interaction. In this letter, we will focus on some features of this scheme for the strong Yukawa coupled standard model from a different point of view. We change the strength of Yukawa coupling in the standard electroweak theory and show that the fundamental ground state of the fermion-Higgs system is not the trivial ground state which is given by the uniform spatial Higgs field and is the non-trivial ground state with hedgehog configuration of Higgs field. The nontrivial ground states give the masses to lepton and quark.

Throughout this letter we work in the classical approximation, i.e. we neglect the radiative corrections due to the boson loops and the contribution of the Dirac sea to the energy of the system. The question of whether these effects are important is beyond the scope of the present letter. On the other hand, the large Yukawa constants in the standard model cannot be included without violating vacuum stability [5]. However, the problem may be overcome by introducing new physics in the TeV region, for example, supersymmetric theories. Therefore, we think that our results for strong coupling model can be qualitatively correct.

We shall first make a brief review on the electroweak standard model. The model contains left-handed and right-handed Weyl fermion fields and $SU(2)_L \times U(1)$ gauge fields A^a and B and a complex Higgs doublet. The Lagrangian of the model is given by $\mathcal{L} = \mathcal{L}_b + \mathcal{L}_f$. The bosonic Lagrangian is

$$\mathcal{L}_b = -\frac{1}{4}F^{a\mu\nu}F_{\mu\nu}^a - \frac{1}{4}G^{\mu\nu}G_{\mu\nu} + (D_\mu \Phi)^\dagger (D^\mu \Phi) - \left(\Phi^\dagger \Phi - \frac{v^2}{2}\right)^2 \quad (1)$$

where $F^{a\mu\nu}$ and $G^{\mu\nu}$ are the $SU(2)_L$ and $U(1)$ fields strength tensor, respectively. The fermionic Lagrangian in the chiral representation reads,

$$\mathcal{L}_f = \bar{\psi}_L i \not{D} \psi_L + \bar{u}_R i \not{D} u_R + \bar{d}_R i \not{D} d_R + \bar{\psi}_U (\bar{\psi}_L \tilde{u}_R + u_R \tilde{\psi}_L) + \bar{\psi}_D (\bar{\psi}_L d_R + d_R \tilde{\psi}_L) \quad (2)$$

where ψ_L denotes the left-handed doublet $(u_L; d_L)$, u_R and d_R are the right-handed singlets, and $\tilde{\psi} = i\gamma_2 \psi^c$. Here, we use (u, d) to represent (up, down) lepton pair and quark pair. In order to discuss the strongly Yukawa coupling model in the follow, we introduced right-handed neutrino to make the neutrino small Dirac mass.

The $SU(2)_L$ gauge symmetry is spontaneously broken due to the non-vanishing VEV v of the Higgs field,

$$\langle \Phi \rangle = \frac{v}{\sqrt{2}} \begin{pmatrix} 0 \\ 1 \end{pmatrix} \quad (3)$$

$$M_W = \frac{1}{2}g_2 v; \quad M_Z = \frac{1}{2}(g_1^2 + g_2^2)^{\frac{1}{2}} v; \quad M_H = v \frac{p}{2}; \quad (4)$$
$$m_U = f_U \frac{v}{2}; \quad m_D = f_D \frac{v}{2} \quad (5)$$
$$\begin{aligned} f_e &< 2:93 \quad 10^{11}; \quad f_e = 2:94 \quad 10^6; \quad f_u = 2:87 \quad 10^5; \quad f_d = 5:75 \quad 10^5; \\ f &< 1:55 \quad 10^6; \quad f = 6:07 \quad 10^4; \quad f_c = 7:47 \quad 10^3; \quad f_s = 1:15 \quad 10^3; \quad (6) \\ f &< 1:78 \quad 10^4; \quad f = 1:02 \quad 10^2; \quad f_t = 1:01 \quad 10^{+0}; \quad f_b = 2:47 \quad 10^2; \end{aligned}$$

To this end, instead of the weakly Yukawa coupling in the Weinberg-Salam model, let us consider the case of the strongly Yukawa coupling. We would like to compare its prediction with a ground state energy estimated in a semi-classical manner. Due to the Higgs field gives the mass of the fermions, we can neglect the gauge degree of freedom with $A^a = B = 0$ in Weinberg-Salam model. By a simple redefinition of Higgs fields

and fermion elds = $L + R$ where R stands for u_R and d_R , then, the Lagrangian L can be written as $L = L + L^0$ with [3]

$$U(\mathbf{r}; \mathbf{v}) = \frac{1}{2} \mathbf{r}^2 + \frac{1}{2} \mathbf{v}^2; \quad (9)$$

and

$$L^0 = \frac{f_U}{2} \frac{f_D}{2} [i_0 (1 - s) + s (1 + i_0)] \quad (10)$$

where $g = (f_U + f_D)/2$ and L is the model Lagrangian. In the following we will see that in the strong coupling model all the Yukawa coupling constants tend to a unitary constant and $(f_U - f_D)$ tends to zero. So, in what follows we shall, then, as a simplification, neglect L^0 leaving us with $L = L$ and set $f_U = f_D = f$.

There is no guarantee that the classical solution (3) gives the lowest possible ground state energy in the fermion sector. In the semi-classical approximation we include only valence fermion and we treat the $(\sigma; \pi)$ fields as classical. We consider the hedgehog solution for which the chiral fields have the form in terms of the fields:

$$(x) = (r); \quad (x) = (r)\hat{r} \quad (11)$$

with $\hat{r} = r/r$. The pion field has then a dipole shape whose space orientation is coupled to the isospin orientation.

With chiral fields of the form (11), the Dirac equation of fermion admits an s-state solution of the form

$$(x) = \frac{1}{4} \frac{G(r)}{i(\hat{r})F(r)} \chi_n; \quad (12)$$

where χ_n is a state in which the spin and isospin of the fermion couple to zero as $(\sigma + \pi)_n = 0$. Taking the ansatz of (11) and (12), minimization of (8) produces the following coupled non-linear equations:

$$\begin{aligned} \frac{1}{r} \frac{d^2}{dr^2} [r F(r)] &= \frac{\partial U}{\partial F} - \frac{g^2}{4} [G^2(r) - F^2(r)]; \\ \frac{1}{r} \left(\frac{d^2}{dr^2} - \frac{2}{r^2} \right) [r G(r)] &= \frac{\partial U}{\partial G} + \frac{g^2}{2} G(r)F(r); \\ \frac{dF(r)}{dr} + \left[\frac{2}{r} - g(r) \right] F(r) + [\epsilon + g(r)] G(r) &= 0; \\ \frac{dG(r)}{dr} + g(r)G(r) + [\epsilon + g(r)] F(r) &= 0; \end{aligned} \quad (13)$$

The quantity ϵ is the eigenvalue of the spinor $\chi_n(x)$ and the radial fermion wave functions are normalized to $\int_0^\infty r^2 dr [F^2(r) + G^2(r)] = 1$.

These equations are supplemented by the following boundary condition:

$$\begin{aligned} (r) &\rightarrow c_1; \quad (r) \rightarrow 0; \quad G(r) \rightarrow c_2; \quad F(r) \rightarrow 0; \quad \text{as } r \rightarrow 0; \\ (r) &\rightarrow v; \quad (r) \rightarrow 0; \quad G(r) \rightarrow 0; \quad F(r) \rightarrow 0; \quad \text{as } r \rightarrow \infty \end{aligned} \quad (14)$$

where c_1 and c_2 are arbitrary constants. These express the fact that the physical vacuum is recovered at infinity. In this 'physical' vacuum the fermions are free Dirac particles of mass gv , and chirality is spontaneously broken.

The hedgehog solution is a self-consistent solution in the sense that, when fermions occupy an orbital of the form (12), the equations in (13) for the chiral fields admit a solution of the form (11). The energy E of the system can be written in the form

$$E = \epsilon + 2 \int_0^{\infty} r^2 dr \left(\left(\frac{d\psi(r)}{dr} \right)^2 + \left(\frac{d\chi(r)}{dr} \right)^2 + \frac{2}{r^2} \psi^2(r) \right) + 2 \int_0^{\infty} r^2 dr \left(\psi^2(r) + \chi^2(r) - v^2 \right) : \quad (15)$$

A state will be bound if its energy E is lower than the mass gv of one free fermion as $E = gv < 1$; a fermion orbital is bound and it decays exponentially at large distance if its energy eigenvalue ϵ is such that $\epsilon < gv$. In the strong coupling model, we would consider that the bound state gives the mass for fermion. The size and energy scale in such a way that once a bound state is found with an appropriate value of g , one can make the energy increase and the size decrease proportionally with v [4].

Before discussing a solution of the coupled set of equations (13), it is instructive to consider a soluble model on chiral circle approximation. When the constant μ in the Lagrangian (8) is large enough, the minimum energy occurs for chiral fields restricted to the chiral circle $\psi^2(r) + \chi^2(r) = v^2$. In this situation it is possible to parametrize the chiral fields by a chiral angle $\theta(r)$:

$$\psi(r) = v \cos \theta(r); \quad \chi(r) = v \sin \theta(r); \quad (16)$$

When one fermion fills an orbital of energy ϵ , the energy (15) of the system can be expressed in terms of the chiral angle as follow:

$$E = \epsilon + 2v^2 \int_0^{\infty} r^2 dr \left(\left(\frac{d\theta(r)}{dr} \right)^2 + \frac{2}{r^2} \sin^2 \theta(r) \right) : \quad (17)$$

It is easy to establish that the equations for $\psi(r)$ and $\chi(r)$ fields in (13) admit solutions which behave as $\psi(r) \sim r^{-n}$ as $r \rightarrow 0$ and $\chi(r) \sim 1/r^2$ as $r \rightarrow \infty$. Let us consider a soluble model in which the chiral angle $\theta(r)$ takes a 'trial' form $\theta(r) = \theta_0 (1 - r/R)$ for $r < R$ and $\theta(r) = 0$ for $r > R$ carried out in Ref. 4 corresponding to the choice $n = 1$. The accuracy of this model is assessed in self-consistent calculation, and it proves quite adequate for discussion of the physics.

A numerical study of the Dirac equations in (13) with the linear form of chiral angle has been carried out in Ref. 4. The energy eigenvalue ϵ is well described by the expression:

$$\epsilon = \frac{3.12}{R} - 0.94gv; \quad (18)$$

valid in the range $2 < R < 12$. By substitute the expression (18) for ϵ and the linear form of the chiral angle into (17) we obtain a schematic expression for the energy of the system as a function of R :

$$E = \frac{3.12}{R} - 0.94gv + 2v^2 \left(1 + \frac{2}{3}\right)R; \quad (19)$$

This equation may be considered as an effective mass formula for the system.

The equilibrium value of R is the value which minimizes the energy (19). One finds $R = 0.34v$, and the minimum energy is then given by

$$E_{\min} = v(18.33 - 0.94g); \quad (20)$$

The coupling constant g in this model must remain in the range $9.5 < g < 19.5$ to make $E_{\min} < gv$ for the system bounded and $E_{\min} > 0$ for energy being non-negative.

We see that, as the Yukawa coupling constant $f = \frac{P}{2g}$ increases, the Higgs field around a fermion tends to go over from a uniform spatial configuration to a hedgehog configuration which gives a decreasing mass with increasing f . We do think that the masses of lepton and quark are given by the hedgehog configuration of Higgs field and not by the usual uniform configuration (3) in the Weinberg-Salam model. According to this idea, the energy of bound state is just the mass of fermion as $E_{\min} = m_f$. The hedgehog configurations of Higgs field give the masses of three generations fermion by the following strongly Yukawa coupling constant y_i (i for leptons and quarks) with

$$y_i = \frac{1}{0.94} (18.33 \frac{P}{2} - f_i); \quad (21)$$

where f_i is the usual Yukawa coupling constant in (6). The y_i are given by:

$$\begin{aligned} y_e &> 27.572998; & y_e &= 27.572996; & y_u &= 27.572969; & y_d &= 27.572938; \\ y &> 27.572998; & y &= 27.572354; & y_c &= 27.565053; & y_s &= 27.571776; \\ y &> 27.572810; & y &= 27.562148; & y_t &= 26.498531; & y_b &= 27.546723; \end{aligned} \quad (22)$$

We found that, the quantitative differences of these Yukawa coupling constants are behind the point except the top quark, these Yukawa coupling constants are towards an

unitary constant and the hierarchy for Yukawa coupling constants is absent. we should point out that all the values in (22) depend on the accuracy of calculation, however, the results presented above do not qualitatively depend on a particular choice for VEV v and the calculating accuracy.

In order to obtain more exact results for strongly Yukawa coupling constant, we solve numerically the non-linear differential equations (13) for eigenvalue λ under the boundary conditions (14) for bound state. Integration of equation set (13), with normalization to one fermion, was performed with the aid of the program COLSYS [6].

In Fig. 1 we show the total energy of the system (15) as a function of the Yukawa coupling constant for one bound fermion and for several values of the Higgs mass. We see that for a given Higgs mass, there exists a critical value of the Yukawa coupling constant above which the fermion can form a stable bound state (as a non-topological soliton [7]), which is lower in energy than the normal mass of one free fermion. These results agree with those of [8]. For a given f , the energy of the bound state (soliton) increases monotonically with the Higgs mass. The energy of the bound state becomes negative for the Yukawa coupling constant $f > 21.0$ for the Higgs masses considered. This value gives the up bound for the Yukawa coupling constant which can be taken.

As same as the soluble model, we think that the bound states give the masses for lepton and quark. From the (15) we see that the energy of the bound state (soliton) depends on both Yukawa coupling constant f and Higgs self-coupling constant λ , So the mass of fermion also depends on both f and M_H . It is different from the standard picture of Weinberg-Salam model in which the mass of fermion can be described alone by Yukawa coupling constant. The strongly Yukawa coupling constants for lepton and quark are given as the following where we take $M_H = v\sqrt{2} = 0.174\text{TeV}$,

$$\begin{aligned} y_e &> 20.789611; & y_e &= 20.789611; & y_u &= 20.789595; & y_d &= 20.789577; \\ y &> 20.789611; & y &= 20.789236; & y_c &= 20.784979; & y_s &= 20.788911; \\ y &> 20.789502; & y &= 20.783310; & y_t &= 20.118602; & y_b &= 20.774090; \end{aligned} \quad (23)$$

These strongly Yukawa coupling constants tend to an unitary constant as similar to the case in the soluble model but with smaller value. Due to the numerical accuracy, the results represented above are not the final values of Yukawa coupling constant for lepton and quark, however, the strongly Yukawa coupling constants do not depend qualitatively on the numerical accuracy.

In Fig. 2 we show the radial functions for the bound state (soliton) with Yukawa coupling constant $y_e = 20.789611$ for electron mass in the case of $M_H = 0.174\text{TeV}$. We see that the fermion is localized in a small region of the space, while the Higgs fields

approach its VEV, where $\langle \phi(r) \rangle \rightarrow v$ and $\langle \phi(r) \rangle \rightarrow 0$, much slowly. We can define the mean-square radius of the bound state as

$$r_0 = \sqrt{\langle r^2 \rangle}; \quad \langle r^2 \rangle = \frac{\int_0^\infty r^4 dr [G^2(r) + F^2(r)]}{\int_0^\infty r^2 dr} \quad (24)$$

The typical radius of the bound state for the lepton and quark is $r_0 = 0.67/\text{TeV}$ with $M_H = 0.174\text{TeV}$. This size is fitting for the limit value of recent experimental data [9]. The typical intrinsic energy scale in this strong coupling model is $M_0 = \sqrt{2} yv = 3.6\text{TeV}$. This leads us to the interesting possibility of probing the size of lepton and quark in next generation collider.

As shown in Fig. 2, the hedgehog configuration of Higgs fields $[\phi(r), \chi(r)]$ obviously appears in the region of small distance (smaller than $1.0/\text{TeV}$) and tends to the uniform configuration in large distance (much bigger than $1.0/\text{TeV}$). On the other hand, the electroweak gauge symmetry is broken at the energy scale of about 100GeV (in the distance of $10.0/\text{TeV}$), in which the hedgehog configuration of Higgs field is close to the normal vacuum configuration (3). So the strong coupling model produces the masses of W and Z almost as same as Weinberg-Salam model. However, there is a little difference from the case of Weinberg-Salam model due to the fact that field $\chi(r)$ is not exactly zero in the region of one hundred GeV . Then, it is possible to research this little difference in recent experiments.

The above physics remains roughly unaltered when we turn on a weakly coupled gauge sector [3]. It is shown that for small gauge coupling the bound state fermion continues to be a good approximation for the one fermion ground state in the standard model. Nolte and Kunz [8] have taken a numerical calculation and show that the change in energy for the strong Higgs-fermion bound state due to the presence of the gauge field is negligible.

In conclusion, we have attempted to give the masses of lepton and quark associated with the electroweak standard model when it carries a strongly coupled Higgs-fermion sector. Within the classical approximation, we have shown that the strongly Yukawa coupling constants for lepton and quark are towards to an unitary constant and the hierarchy for Yukawa coupling constants is absent. On the other hand, in the strong coupling model, the masses of W and Z produced by the hedgehog configuration of Higgs field keep almost no change. The mass of fermions depends slightly on the mass of Higgs boson in the tree level, then, this relation should shed light on hunting for the Higgs boson.

The strong coupled Higgs-fermion bound state (soliton) may be unstable with the quantum radiative corrections [10]. This possible quantum instability should be the

common problem in the non-point model for lepton and quark. It is due to the fact that the resulting bound states have the sizes, which are so much smaller than their Compton wavelengths. This fact is only understandable dynamically if there exists an approximate symmetry which forces certain bound states to have nearly zero mass. On the other hand, the strongly Yukawa coupling in the standard model will violate the vacuum stability [5] due to the radiative corrections, then, we should improve the standard model with new physics in the TeV region. So, in order to stabilize the bound states for fermion and Higgs vacuum structure against quantum effects, it should introduce new symmetry into the standard model, such as supersymmetry.

The author is indebted to Dr. D. H. Zhang for help in drafting on computer.
