In light-front dynamics, the regularization of amplitudes by traditional cut-offs imposed on the transverse and longitudinal components of particle momenta corresponds to restricting the integration volume by a non-rotationally invariant domain. The result depends not only on the size of this domain (i.e., on the cut-off values), but also on its orientation determined by the position of the light-front plane. Explicitly covariant formulation of light front dynamics allows us to parameterize the latter dependence in a very transparent form. If we decompose the regularized amplitude in terms of independent invariant amplitudes, extra (non-physical) terms should appear, with spin structures which explicitly depend on the orientation of the light front plane. The number of form factors, i.e., the coefficients of this decomposition, therefore also increases. The spin-1/2 fermion self-energy is determined by three scalar functions, instead of the two standard ones, while for the elastic electromagnetic vertex the number of form factors increases from two to five. In the present paper we calculate perturbatively all these form factors in the Yukawa model. Then we compare the results obtained in the two following ways: (i) by using the light front dynamics graph technique rules directly; (ii) by integrating the corresponding Feynman amplitudes in terms of the light front variables. For each of these methods, we use two types of regularization: the transverse and longitudinal cut-offs, and the Pauli-Villars regularization. In the latter case, the dependence of amplitudes on the light front plane orientation vanishes completely provided enough Pauli-Villars subtractions are made.

I. INTRODUCTION

Light-Front Dynamics (LFD) is extensively and successfully applied to hadron phenomenology, relativistic few-body systems, and field theory. For reviews of theoretical developments and applications see, e.g., Refs. [1, 2]. In the LFD framework, non-perturbative approaches to field theory were developed in Refs. [3, 4, 5] and in Refs. [6, 7, 8]. In spite of some essential differences, these approaches proceed from the same starting point, namely, they approximate the state vector of the system by a truncated one. The problem is then solved without any decomposition in powers of the coupling constant. Doing that, one should carry out the renormalization procedure non-perturbatively. This is a non-trivial problem which is at the heart of ongoing intense research. However, before renormalization, one should regularize the amplitudes, both in the perturbative and non-perturbative frameworks. The explicit dependence of these amplitudes on the cut-offs is not unique. It is determined by the method of regularization.

It is of utmost importance to understand the origin and the implications of this dependence if one wants to address the question of non-perturbative renormalization. As we shall show in the present article, this is the only way to identify the structure of the counterterms needed to recover full rotationally invariant renormalized amplitudes in LFD. The question of the non-perturbative determination of the counterterms in truncated Fock space

is discussed in Ref. [8].

The rules for calculating amplitudes can be derived directly, either by transforming the standard T-ordering of the S-matrix into the ordering along the Light Front (LF) time (the LFD graph technique rules [1]), or from quantized field theory on the LF plane [2]. An alternative method consists in expressing well-defined Feynman amplitudes through the LF variables and integrating over the minus-components of particle momenta [9, 10]. Such an approach was applied to the derivation and study of the LF electromagnetic amplitudes [11, 12] and to the analysis of different contributions to the electromagnetic current, resulting from the LF reduction of the Bethe-Salpeter formalism [13]. A study of electroweak transitions of the spin-1 mesons, based on using the LF plane of general orientation [1], was carried out in Refs. [14, 15]. The comparison of perturbative amplitudes obtained from the LFD graph technique rules with those derived from the Feynman approach is, in general, not trivial, as shown in Ref. [16].

Concerning the regularization of amplitudes in LFD, at least two important features should be mentioned. First, if a given physical process is described by a set of LF diagrams, each partial LF amplitude usually diverges more strongly than the Feynman amplitude of the same process. The statement holds true regardless of the origin of the LF contributions: either from the rules of LFD, or from the Feynman amplitude. This increases the sensitivity of the result to the choice of the regularization

procedure and may be a source of the so-called treacherous points [17]. Second, the LF variables (and, hence, the integration domain with the cut-offs imposed on it) explicitly depend on the LF plane orientation, which means the loss of rotational invariance. Because of this extra dependence, standard decompositions of such regularized LF amplitudes into invariant amplitudes are not valid. The total number of invariant amplitudes (and the number of form factors which are the coefficients in this decomposition) increases, as compared to the case when the rotational invariance is preserved. For example, the LF electromagnetic vertex (EMV) of a spin-1/2 particle is determined by two form factors rather than by two. In order to cancel the extra contributions (which depend on the LF plane orientation) one needs to introduce in the interaction Hamiltonian new specific counterterms.

This complication is especially dramatic in non-perturbative approaches, where the Fock space truncation is another source of the rotational symmetry violation. A given Feynman diagram may generate a few time-ordered ones with intermediate states containing different number of particles. When they are truncated, the rotational invariance is lost even for invariant cut-offs. The interlacing of the two sources of the violation of rotational symmetry makes non-perturbative analysis of the counterterm structure extremely involved. One should therefore separate to a maximal extent the problems coming from the regularization procedure and from the Fock space truncation. That can be effectively done in the explicitly covariant formulation of LFD within the perturbative framework in a given order in the coupling constant.

In the present paper we study in detail this problem for the spin-1/2 fermion perturbative self-energy and the elastic EMV in the Yukawa model within the framework of explicitly covariant LFD [1]. The latter deals with the LF plane of general orientation $\hat{n} \cdot \mathbf{x} = 0$, where \hat{n} is a four-vector with $\hat{n}^2 = 0$. In the particular case $\hat{n} = (1; 0; 0; 1)$ we recover the standard approach on the plane $t + z = 0$. Due to \hat{n} , which is transformed as a four-vector under rotations and Lorentz boosts, we can keep manifest rotational invariance throughout the calculations. Dependence of amplitudes on the LF plane orientation turns now in their dependence on the four-vector \hat{n} . The latter participates in the construction of the spin structures in which the regularized initial LF amplitude can be decomposed, on equal footing with the particle four-momenta. This generates extra (\hat{n} -dependent) spin structures with corresponding scalar coefficients (e.g., electromagnetic form factors). The number of the extra spin structures and their explicit forms are determined by general physical principles (more precisely, by the particle spins and the symmetries of the interaction), i.e., they are universal for any model and do not depend on particular features of dynamics. Whereas, the dependence of the extra coefficients on particle four-momenta is determined by the model. This allows to separate general properties, related to LFD itself, from model-dependent

effects.

We shall proceed in the following two ways, both for the self-energy and the EMV. In the first way, we calculate these quantities by the LFD graph technique rules, taking into account all necessary diagrams. In the second way, we start from the standard Feynman amplitudes and integrate them in terms of the LF variables. For both ways, we have to introduce cut-offs on the LF variables, and this fact already implies the contribution of extra (\hat{n} -dependent) structures and their corresponding form factors. The regularized self-energy and the EMV calculated by means of the LFD graph technique rules do not coincide in general with their counterparts obtained from the Feynman amplitudes. For the EMV case, the vertex found from the Feynman amplitude with the cut-offs imposed on the LF variables, also differs from that calculated in a standard way, by the Wick rotation with a spherically symmetric cut-off or by the Pauli-Villars (PV) regularization. All these differences disappear when we deal with integrals which are finite from the very beginning (e.g., due to the PV regularization). They disappear also in the renormalized amplitudes, though renormalization procedures (counterterms, etc.) are drastically different for different regularization schemes.

Within covariant LFD, the perturbative QED self-energy and the EMV in the channel of the fermion-antifermion pair creation have been studied earlier [18]. The main subject was to extract the physical (\hat{n} -independent) contributions from the corresponding amplitudes and to renormalize this physical part only. The present analysis is devoted to a more detailed treatment of the self-energy and the EMV. We calculate both physical and non-physical contributions in the two ways mentioned above and investigate the influence of the regularization procedure on the whole amplitudes and on their subsequent renormalization. The Yukawa model which we use reflects some features of QED but it is simpler from the technical point of view.

The paper is organized as follows. In Sec. II we briefly describe the LFD graph technique rules and apply them to calculate the fermion self-energy. We use two different regularization procedures, the transverse and longitudinal LF cut-offs or PV subtractions, either for the bosonic, or simultaneously for both bosonic and fermionic propagators. Then we calculate the fermion self-energy, starting from the manifestly invariant Feynman amplitude expressed through the LF variables and regularized in the same way as the LFD one. We compare the results obtained in both approaches and analyze how they are affected by the choice of regularization. In Sec. III we repeat analogous steps for the fermion EMV. For this purpose, we derive the LF interaction Hamiltonian which includes fermion-boson and fermion-photon interactions. We then construct the complete set of the LF diagrams which contribute to the EMV. We use again the non-invariant LF cut-offs and the invariant PV regularization. The LFD form factors are compared to those obtained in terms of the Feynman amplitude with the same type of

regularization. General discussion of our results is presented in Sec. IV. Sec. V contains concluding remarks. The technical details of some derivations are given in the Appendices.

II. THE FERMION SELF-ENERGY

The fermion self-energy is the simplest example of how an extra spin structure is generated by rotationally non-invariant cutoffs in LFD. To make the situation more transparent, we will calculate the self-energy independently in the two following ways: (1) by applying the covariant LFD graph technique rules; (2) by using the four-dimensional Feynman approach. In each case we consider two different types of regularization of divergent integrals: either the traditional rotationally non-invariant cutoffs or the invariant PV regularization. We then renormalize the amplitudes and compare the results obtained with in these two methods.

A. Calculation in light-front dynamics

1. Light-front diagrams and their amplitudes

We calculate in this section the fermion self-energy in the second order of perturbation theory, using the graph technique rules of explicitly covariant LFD [1, 7, 19]. We do it in details in order to explain the rules on a concrete example.

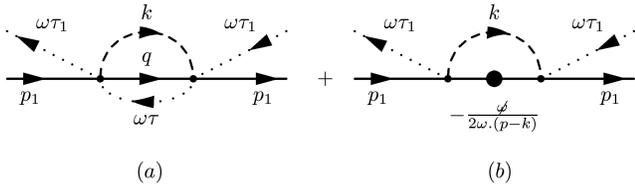

FIG. 1: Two contributions to the LFD fermion self-energy $\Sigma(p)$: the two-body intermediate state (a) and the contact term (b). The solid, dashed, and dotted lines represent, respectively, the fermion, the boson, and the spurion. Here $p = p_1 + \epsilon_1$, where ϵ_1 is the four-momentum attached to the initial (or final) spurion line. See text for the explanation.

The self-energy $\Sigma(p)$ is determined by the sum of the two diagrams shown in Fig. 1,

$$\Sigma(p) = \Sigma_{2b}(p) + \Sigma_{fc}(p); \quad (1)$$

They correspond to the two-body contribution and the fermion contact term, respectively. Analytical expres-

sions for the corresponding amplitudes read

$$\Sigma_{2b}(p) = \frac{g^2}{(2\pi)^3} \int d^4k \int d^4q \frac{(\not{p} + \not{k} + \not{q})}{i0} \frac{1}{2! (\not{p} - \not{k})}; \quad (2a)$$

$$\Sigma_{fc}(p) = \frac{g^2}{(2\pi)^3} \frac{1}{2! (\not{p} - \not{k})} \int d^4k; \quad (2b)$$

where g is the coupling constant of the fermion-boson interaction, m and ϵ are the fermion and boson masses, respectively. In the covariant LFD graph technique, all the four-momenta are on the corresponding mass shells. This is due to the fact that the propagators are proportional to delta-functions: $(\not{p} - \not{k})^{-1}$ is the boson propagator, $(\not{q} + m)$ is the fermion one. Each theta-function $\theta(\epsilon_1)$ selects only one value of $\epsilon = \epsilon_1^2 + m_1^2$, of the two possible ones allowed by the corresponding delta-function $\delta(\epsilon - m_1^2)$. There is no any conservation law for the components of particle four-momenta in the direction of ϵ_1 (or for the minus-components, in the standard version of LFD). The conservation is restored by the spurion four-momentum ϵ_1 which enters the delta-function $\delta(\epsilon_1 + \epsilon - k^2 - q^2)$. The factor $1/(i0)$ is the spurion propagator and the ϵ_1 -integration is performed in infinite limits. To avoid misunderstanding, we emphasize that spurions are not true particles and do not affect particle counting. They serve as a convenient way to describe the departure of intermediate particles from the energy shell. The term "spurion" itself is used for shorter wording only. For this reason, the intermediate state in the self-energy (2a) contains one fermion and one scalar boson only. The self-energy is supposed to be on-energy-shell, i.e., $\epsilon_1 \in 0$.

Integrating by means of the delta-functions over d^4q , $d\epsilon_1$, and dk_0 , we get

$$\Sigma_{2b}(p) = \frac{g^2}{(2\pi)^3} \int d^3k \int d^3q \frac{(\not{p} + \not{k} + \not{q})}{2! (\not{p} - \not{k})} \frac{1}{2! k_k}; \quad (3a)$$

$$\Sigma_{fc}(p) = \frac{g^2}{(2\pi)^3} \frac{1}{2! (\not{p} - \not{k})} \int d^3k; \quad (3b)$$

where $k_k = \int d^3k \frac{1}{k^2 + m^2}$ and

$$= \frac{m^2}{2! (\not{p} - \not{k})}; \quad (4)$$

Let us go over to the LF variables. First, we denote $x = (\not{p} - \not{k}) = (\not{p} - \not{k})$ (equivalent to \not{p}^+ in standard non-covariant LFD on the surface $t+z=0$). We then split the three-vector k into two parts: $k = k_\perp + k_\parallel$, which are, respectively, perpendicular and parallel to the three-vector ϵ_1 . Since $\Sigma(p)$ is an analytic function of p^2 , we

may calculate it for $p^2 > 0$, while its values for $p^2 = 0$ are obtained by the analytical continuation. If $p^2 > 0$, we may perform our calculation in the reference frame where

$p = 0$. Using the kinematical relations from Appendix A, one can rewrite Eqs. (3) as

$$2b(p) = \frac{g^2}{16^3} \int_0^Z d^2 k_{\perp} \int_0^1 \frac{(\not{p} \not{k} + m) dx}{k_{\perp}^2 + m^2 x \not{p}^2 x(1-x) + m^2(1-x)} \frac{g^2 \not{p}}{32^3 (! p)} \int_0^Z d^2 k_{\perp} \int_0^1 \frac{dx}{x(1-x)}; \quad (5a)$$

$$f_c(p) = \frac{g^2 \not{p}}{32^3 (! p)} \int_0^Z d^2 k_{\perp} \int_0^1 \frac{dx}{x(1-x)}; \quad (5b)$$

Both $2b(p)$ and $f_c(p)$ are expressed through integrals which diverge logarithmically in x and quadratically in k_{\perp}^2 . Possible regularization procedures are discussed below.

Following Ref. [7], we will use the matrix representation

$$2b(p) = g^2 A(p^2) + B(p^2) \frac{\not{p}}{m} + C(p^2) \frac{m \not{p}}{! p}; \quad (6a)$$

$$f_c(p) = g^2 C_{fc} \frac{m \not{p}}{! p}; \quad (6b)$$

where the coefficients A , B , and C are scalar functions which depend on p^2 only. They are independent of $!$. The coefficient C_{fc} is a constant. The self-energy is thus obtained by summing up Eqs. (6):

$$(p) = g^2 A(p^2) + B(p^2) \frac{\not{p}}{m} + [C(p^2) + C_{fc}] \frac{m \not{p}}{! p}; \quad (7)$$

Note that in the expression (7) an additional spin structure proportional to \not{p} appears, as compared to the standard four-dimensional Feynman approach.

2. Regularization with rotationally non-invariant cut-offs

In order to regularize the integrals over $d^2 k_{\perp}$, we introduce a cut-off Λ , so that $k_{\perp}^2 < \Lambda^2$. Since some integrals over dx diverge logarithmically at $x = 0$ and/or $x = 1$, we also introduce (where it is needed) an infinitesimal positive cut-off ϵ , assuming that x may belong to the intervals $0 < x < 1 - \epsilon$ and $1 + \epsilon < x < 1 + 1$. The corresponding analytical expressions for the functions $A(p^2)$, $B(p^2)$, $C(p^2)$, and C_{fc} were found in Ref [7]:

$$A(p^2) = \frac{m}{16^2} \int_0^{\Lambda^2} dk_{\perp}^2 \int_0^1 dx \frac{1}{k_{\perp}^2 + m^2 x \not{p}^2 x(1-x) + m^2(1-x)}; \quad (8a)$$

$$B(p^2) = \frac{m}{16^2} \int_0^{\Lambda^2} dk_{\perp}^2 \int_0^1 dx \frac{x}{k_{\perp}^2 + m^2 x \not{p}^2 x(1-x) + m^2(1-x)}; \quad (8b)$$

$$C(p^2) = \frac{1}{32^2 m} \int_0^{\Lambda^2} dk_{\perp}^2 \int_0^1 dx \frac{k_{\perp}^2 + m^2 \not{p}^2 (1-x)^2}{(1-x) [k_{\perp}^2 + m^2 x \not{p}^2 x(1-x) + m^2(1-x)]}; \quad (8c)$$

$$C_{fc} = \frac{1}{32^2 m} \int_0^{\Lambda^2} dk_{\perp}^2 \left[\int_0^1 \frac{dx}{x(1-x)} + \int_{1+\epsilon}^{\Lambda^2} \frac{dx}{x(1-x)} \right]; \quad (8d)$$

We imply in the following that $\Lambda^2 = m^2 \alpha^2 \not{p}^2 / m^2$; $\alpha^2 g$ and $\epsilon = 1$. The dependence of physical results on the cut-off is eliminated by taking the limits $\Lambda^2 \rightarrow \infty$, $\epsilon \rightarrow 0$.

Retaining in Eqs. (8) all terms which do not vanish in these limits, we get

$$A(p^2) = \frac{m}{8^{\frac{2}{\epsilon}}} \log \frac{\mu}{m} + \frac{m}{16^{\frac{2}{\epsilon}}} \int_0^1 dx \log \frac{m^2 x - p^2 x(1-x) + \mu^2(1-x)}{m^2}; \quad (9a)$$

$$B(p^2) = \frac{m}{16^{\frac{2}{\epsilon}}} \log \frac{\mu}{m} + \frac{m}{16^{\frac{2}{\epsilon}}} \int_0^1 dx (1-x) \log \frac{m^2 x - p^2 x(1-x) + \mu^2(1-x)}{m^2}; \quad (9b)$$

$$C(p^2) = \frac{\mu^{\frac{2}{\epsilon}}}{32^{\frac{2}{\epsilon}} m} \log \frac{1}{m} - \frac{m^{\frac{2}{\epsilon}}}{16^{\frac{2}{\epsilon}} m} \log \frac{\mu}{m} - \frac{1}{32^{\frac{2}{\epsilon}} m} m^{\frac{2}{\epsilon}} \mu^{\frac{2}{\epsilon}} \log \frac{m}{\mu}; \quad (9c)$$

$$C_{fc} = \frac{\mu^{\frac{2}{\epsilon}}}{32^{\frac{2}{\epsilon}} m} \log \frac{1}{\mu}; \quad (9d)$$

We have not integrated over dx in Eqs. (9a) and (9b) because the results of the integrations are rather long. It is interesting to note that $C(p^2)$ does not depend on p^2 . Due to this, we will denote in the following $C(p^2) = C = \text{const}$ and, for shortness, $C = C + C_{fc}$.

Each of the two quantities, C and C_{fc} diverges like $\mu^{\frac{2}{\epsilon}} \log(\mu)$. The strongest divergencies cancel in the sum $C = C + C_{fc}$, but the latter differs from zero and, moreover, has no finite limit when $\epsilon \rightarrow 1$:

$$C = \frac{m^{\frac{2}{\epsilon}}}{16^{\frac{2}{\epsilon}} m} \log \frac{\mu}{m} - \frac{1}{32^{\frac{2}{\epsilon}} m} m^{\frac{2}{\epsilon}} \mu^{\frac{2}{\epsilon}} \log \frac{m}{\mu}; \quad (10)$$

Since the two diagrams shown in Fig. 1 exhaust the full set of the second-order diagrams which contribute to the fermion self-energy, we might expect the disappearance of every μ -dependent contribution from the amplitude. As far as this does not take place, the only source of the μ -dependence is the use of the rotationally non-invariant cut-offs for the LF variables k_{\parallel}^2 and x . Indeed, if we write these variables in the explicitly covariant form

$$k_{\parallel}^2 = 2 \frac{(\not{k} \cdot p)(\not{k} \cdot p)}{\not{k} \cdot p} p^2 - \frac{\not{k} \cdot k^2}{\not{k} \cdot p}; \quad x = \frac{\not{k} \cdot k}{\not{k} \cdot p}$$

it becomes evident that both of them depend on μ . Introducing the cut-offs μ_{\parallel}^2 and μ_{\perp} , we restrict an μ -dependent integration domain, which inevitably brings μ -dependence into the regularized quantities. We will demonstrate this feature in more detail in Sec. IV by using a very simple and transparent example. Note that without adding new, μ -dependent, counterterms in the interaction Hamiltonian, this dependence is not killed by the standard renormalization. The renormalization recipe must be therefore modified [7].

3. Invariant Pauli-Villars regularization

As we learned above, the source of the appearance of the extra (μ -dependent) term in the regularized fermion

self-energy is the μ -dependence of the integration domain. A standard way free from this demerit is the use of the PV regularization, since in that case the cut-offs have no more relation to μ . In the language of LFD, the PV regularization consists in changing the propagators as

$$(\not{k} - m)^{-1} \rightarrow (\not{k} - m)^{-1} [(\not{k} - m)^{-1} - (\not{k} - m_1)^{-1}]$$

for scalar bosons, and

$$(\not{q} + m)^{-1} \rightarrow (\not{q} + m)^{-1} [(\not{q} + m)^{-1} - (\not{q} + m_1)^{-1}]$$

for fermions. This procedure is equivalent to introducing additional particles (one PV fermion with the mass m_1 and one PV boson with the mass m_1), whose wave functions have negative norms. If needed, more subtractions can be done till all integrals become convergent. After the calculation of the integrals and the renormalization, the limits $m_1 \rightarrow 1$ and $m_1 \rightarrow 1$ should be taken. In the case of the fermion self-energy, we may regularize either the boson propagator only, or the fermion one, or both simultaneously. Hereafter we will supply PV-regularized quantities with the superscript "PV;b" (when only the bosonic propagator is modified) or "PV;b+f" (when both bosonic and fermionic propagators are modified).

Let us now calculate the PV-regularized coefficients $A(p^2)$, $B(p^2)$, and C . We can start from the expressions (9), in spite of their dependence on the "old" cut-offs μ_{\parallel}^2 and μ_{\perp} . Indeed, the integrals in Eqs. (9) become regular, provided enough PV subtractions have been made. If so, they have definite limits at $\epsilon \rightarrow 1$ and $\mu \rightarrow 0$.

The integrals for $A(p^2)$ and $B(p^2)$ become convergent after the regularization by a PV boson only:

$$A^{PV;b}(p^2) = A(p^2; m; \epsilon) \quad A(p^2; m; \epsilon_1) = \frac{m}{16^2} \int_0^1 dx \log \frac{m^2 x}{m^2 x} \frac{p^2 x(1-x) + \epsilon^2(1-x)}{p^2 x(1-x) + \frac{\epsilon^2}{1}(1-x)}; \quad (11a)$$

$$B^{PV;b}(p^2) = B(p^2; m; \epsilon) \quad B(p^2; m; \epsilon_1) = \frac{m}{16^2} \int_0^1 dx (1-x) \log \frac{m^2 x}{m^2 x} \frac{p^2 x(1-x) + \epsilon^2(1-x)}{p^2 x(1-x) + \frac{\epsilon^2}{1}(1-x)}; \quad (11b)$$

The situation differs drastically for the coefficient C . After the bosonic PV regularization we get

$$C^{PV;b} = \frac{1}{32^2 m} \left(\epsilon^2 - \frac{\epsilon^2}{1} \right) \left[1 + 2 \log \frac{\epsilon^2}{m} + 2 \epsilon^2 \log \frac{m}{\epsilon^2} - 2 \frac{\epsilon^2}{1} \log \frac{m}{\epsilon^2} \right]; \quad (12)$$

Since the result is still divergent for $\epsilon \neq 1$, this regularization is not enough. The additional fermionic PV regularization requires some care because C is a coefficient at the spin structure $\mathcal{G} = (\not{p})$ which itself depends on m . Hence, one should regularize the quantity mC :

$$mC^{PV;b+f} = mC(m; \epsilon) - mC(m; \epsilon_1) \\ m_1 C(m_1; \epsilon) + m_1 C(m_1; \epsilon_1) = 0; \quad (13)$$

We see that after the double PV regularization the extra structure in Eq. (7), proportional to \mathcal{G} , disappears, as it should. Note that Eq. (13) holds for arbitrary (i.e., not necessary infinite) PV masses m_1 and ϵ_1 .

4. Renormalization procedure

The renormalized self-energy is obtained by using the standard procedure:

$$\Sigma_{ren}^{PV;b+f}(p) = \Sigma^{PV;b+f}(p) - \mathcal{G} \mathcal{G}(\not{p} - m); \quad (14)$$

where

$$c_1 = \frac{u(p) \Sigma^{PV;b+f}(p) u(p)}{2m} \Big|_{p^2=m^2}; \quad (15a)$$

$$c_2 = \frac{1}{2m} u(p) \frac{\mathcal{G} \Sigma^{PV;b+f}(p)}{\mathcal{G} \not{p}} u(p) \Big|_{p^2=m^2}; \quad (15b)$$

Finally,

$$\Sigma_{ren}^{PV;b+f}(p) = g^2 [A_{ren}(p^2) + B_{ren}(p^2) \frac{\not{p}}{m}]; \quad (16)$$

with

$$A_{ren}(p^2) = A(p^2) - A(m^2) + 2m^2 [A^0(m^2) + B^0(m^2)]; \quad (17a)$$

$$B_{ren}(p^2) = B(p^2) - B(m^2) - 2m^2 [A^0(m^2) + B^0(m^2)]; \quad (17b)$$

In order to calculate $A_{ren}(p^2)$ and $B_{ren}(p^2)$ we can use the initial functions $A(p^2)$ and $B(p^2)$ regularized either by the non-invariant cut-offs, Eqs. (9a) and (9b), or by means of the PV regularization, Eqs. (11). Any choice leads to the same result:

$$A_{ren}(p^2) = \frac{m}{16^2} \int_0^1 dx [c_1(x) - c_2(x)]; \quad (18a)$$

$$B_{ren}(p^2) = \frac{m}{16^2} \int_0^1 dx (1-x) [c_1(x) + c_2(x)]; \quad (18b)$$

where

$$c_1(x) = \log \frac{m^2 x}{m^2 x^2 + \epsilon^2(1-x)} \frac{p^2 x(1-x) + \epsilon^2(1-x)}{p^2 x(1-x) + \frac{\epsilon^2}{1}(1-x)}; \\ c_2(x) = \frac{2m^2 x(2-3x+x^2)}{m^2 x^2 + \epsilon^2(1-x)};$$

The remaining integrations over dx in Eqs. (18) are simple but lengthy.

B. Calculation in the four-dimensional Feynman approach

1. Regularization with rotationally non-invariant cut-offs

We showed above that the regularized fermion self-energy calculated within LFD with the traditional transverse (ϵ_\perp) and longitudinal (ϵ_\parallel) cut-offs contains an extra spin structure depending on \not{p} . In order to understand the reasons of this behavior, we calculate here the self-energy in another way, following Ref. [9]. We start from the standard four-dimensional Feynman expression

$$\Sigma(p) = \frac{ig^2}{(2)^4} \int d^4 k \frac{\not{p} \not{k} + m}{[k^2 - \epsilon^2 + i0][p-k]^2 - m^2 + i0]; \quad (19)$$

but perform the integrations in terms of the LF variables, with the corresponding cut-offs. For this purpose, we introduce the minus-, plus-, and transverse components of the four-momentum k :

$$k = k_0 \not{\epsilon}_z; \quad k_+ = k_0 + k_z; \quad k_\perp = (k_x; k_y);$$

and analogously for p . As in Sec. IIA 1, we take, for convenience, the reference frame where $p = 0$. In this

from eq. (19) = $p^2 = p_+^2$. Denoting $k_+ = xp_+$, we get

$$F(p) = \frac{ig^2 p_+^2}{32} \int_{-1}^1 dx \int_{-1}^1 dk \frac{1}{[k^2 + m^2 x^2 + i0]^{L+1}} \frac{1}{(k^2 + m^2)} \quad (20)$$

with

$$k^2 = \frac{1}{2} + k + \frac{x}{2} p_+^2 - k^2$$

The integral over dk is calculated by using the principal value prescription:

$$\int_{-1}^1 dk \frac{1}{k^2 + m^2} = \lim_{L \rightarrow \infty} \int_{-1}^1 dk \frac{1}{k^2 + m^2 + i0} \quad (21)$$

This integral is well defined unless $x = 0$ or $x = 1$. If $x = 0$ or $x = 1$, the integral (21) diverges on the upper and lower limits. So, the infinitesimal integration domains near the points $x = 0$ and $x = 1$ (the so-called zero modes) require special consideration. We introduce a cut-off in the variable x and represent $F(p)$ as a sum

$$F(p) = p_{+a}(p) + z_m(p); \quad (22)$$

where $p_{+a}(p)$ incorporates the contributions from the regions of integration over dx ($0 < x < 1$), excluding the singular points $x = 0$ and $x = 1$, while the zero-mode part $z_m(p)$ involves the integrations in the vicinities of these two points.

The calculation is carried out in Appendix B. After closing the integration contour by an arc of a circle (see Appendix B), the integral for $p_{+a}(p)$ is represented as a sum of the pole and arc contributions and has the form

$$p_{+a}(p) = \frac{g^2}{16} \int_{-1}^1 dx \frac{1}{[k^2 + m^2 x^2 + i0]^{L+1}} \frac{1}{(k^2 + m^2)} + \frac{g^2}{32} \int_{-1}^1 dx \frac{1}{[k^2 + m^2 x^2 + i0]^{L+1}} \frac{1}{(k^2 + m^2)} \quad (23)$$

Comparing Eq. (23) with Eqs. (5), we see that

$$p_{+a}(p) = z_b(p) + f_c(p); \quad (24)$$

where both terms on the right-hand side are regularized at $x = 0$ and $x = 1$. The pole plus arc contributions to Eq. (20) reproduce the result given by the sum of the two LFD diagrams shown in Fig. 1. Hence,

$$p_{+a}(p) = g^2 A(p^2) + B(p^2) \frac{1}{m} + C_{p+a} \frac{m}{p}; \quad (25)$$

where $A(p^2)$ and $B(p^2)$ are defined by Eqs. (9a) and (9b), while C_{p+a} coincides with C , Eq. (10).

As mentioned above, the zero-mode contribution results from the divergence (at $L \rightarrow \infty$) of the integral over k , which occurs when $x = 0; 1$. This divergence is determined by the leading k -term in the numerator of Eq. (20), that is by $\frac{1}{2} + k$. In explicitly covariant LFD, the matrix γ_5 turns into θ . The zero-mode contribution is therefore

$$z_m(p) = g^2 C_{z_m} \frac{m}{p}; \quad (26)$$

where C_{z_m} is calculated in Appendix B and has the form

$$C_{z_m} = \frac{m^2}{16} \log \frac{1}{m} + \frac{1}{32} m^2 \log \frac{m}{2} \quad (27)$$

We thus find

$$C_{p+a} + C_{z_m} = 0; \quad (28)$$

since $C_{p+a} = C$ is given by the right-hand side of Eq. (10). Substituting Eqs. (25) and (26) into Eq. (22), and taking into account Eq. (28), we finally get

$$F(p) = g^2 A(p^2) + B(p^2) \frac{1}{m}; \quad (29)$$

We see that after the incorporation of the pole, arc, and zero-mode contributions, the L -dependent term in the self-energy disappears, even before the renormalization. Note that although we used the same cut-offs, the formula (29) does not coincide with the expression (7) obtained by using the LFD graph technique rules, since the sum $C(p^2) + C_{fc}$ is not zero [it is given by Eq. (10)]. One might think that the dependence of the self-energy (7) on L is an artefact of the LFD rules, whereas the independence of the Feynman approach on L is natural, since we started with the Feynman expression (19) which "knows nothing" about L . It is not so, since the initially divergent integral for $F(p)$ acquires some sense only after regularization, and the latter has been done in terms of the cut-offs imposed on the LF variables. The independence of $F(p)$ on L looks thereby as a coincidence. We shall see in Sec. IIIB that, in the EMV case, in contrast to the self-energy one, the LF cut-offs applied to the initial Feynman integral do result in some dependence of the EMV on the LF plane orientation.

After the renormalization, Eq. (29) reproduces the expression (16) obtained earlier for the self-energy found within LFD and regularized by the invariant PV method.

2. Invariant regularization

We briefly recall in this section familiar results known from the standard four-dimensional Feynman formalism

which is completely independent from LFD. It may serve as an additional test of the results obtained above.

The fermion self-energy is given by Eq. (19). It is convenient to use the following decomposition:

$$\Sigma_F(p) = g^2 A_F(p^2) + B_F(p^2) \frac{\not{p}}{m}; \quad (30)$$

where $A_F(p^2)$ and $B_F(p^2)$ are scalar functions. Note that they do not coincide with $A(p^2)$ and $B(p^2)$ from Eq. (29), since we use here another regularization procedure. Applying the Feynman parameterization, we can rewrite Eq. (19) as

$$\Sigma_F(p) = \frac{ig^2}{16^4} \int_0^1 dx \int d^4k^0 \frac{(1-x)\not{p} + m}{[k^0^2 - m^2x + p^2x(1-x) - 2(1-x) + i0]^2}; \quad (31)$$

where we introduced $k^0 = k \cdot \gamma$. Going over to Euclidean space by means of the Wick rotation $k_0^0 = ik_4^0$ with real k_4^0 and regularizing the divergent integrals by an invariant cutoff $k^0^2 = k^0^2 + k_4^0{}^2 < \Lambda^2$ (assuming that $\Lambda^2 \gg m^2, p^2$), we can perform the four-dimensional integration and get

$$\Sigma_F(p) = \frac{g^2}{16^2} \int_0^1 dx [(1-x)\not{p} + m] \log \frac{\Lambda^2}{m^2x - p^2x(1-x) + 2(1-x)}; \quad (32)$$

The terms of order Λ^{-2} and higher are omitted. Comparing the right-hand sides of Eqs. (30) and (32), we find

$$A_F(p^2) = \frac{m}{16^2} \log \frac{\Lambda^2}{m^2} + \frac{m}{16^2} \int_0^1 dx \log \frac{m^2x - p^2x(1-x) + 2(1-x)}{m^2}; \quad (33a)$$

$$B_F(p^2) = \frac{m}{32^2} \log \frac{\Lambda^2}{m^2} + \frac{m}{16^2} \int_0^1 dx (1-x) \log \frac{m^2x - p^2x(1-x) + 2(1-x)}{m^2}; \quad (33b)$$

The renormalized self-energy $\Sigma_{F;ren}(p)$ is found from Eq. (14), changing $\Sigma^{PV;b+f}(p)$ by $\Sigma_F(p)$. The corresponding renormalized functions $A_{F;ren}(p^2)$ and $B_{F;ren}(p^2)$ coincide with $A_{ren}(p^2)$ and $B_{ren}(p^2)$ given by Eqs. (18). We thus reproduce again Eq. (16) for $\Sigma_{F;ren}(p)$.

It is easy to verify that using the PV subtraction for the boson propagator (instead of the cutoff),

$$\Sigma_F^{PV;b}(p) = \Sigma_F(p; m; \Lambda) - \Sigma_F(p; m; 1);$$

leads, in the limit $\Lambda \rightarrow \infty$, to the same expression (16) for the renormalized self-energy. We have therefore

$$\Sigma_{F;ren}(p) = \Sigma_{F;ren}^{PV;b}(p) = \Sigma_{F;ren}^{PV;b+f}(p); \quad (34)$$

To conclude, any of the considered ways of regularization (either with the non-invariant cutoff Λ and or with the single bosonic PV subtraction) can be used in order to get the correct expression for the renormalized self-energy in the Feynman approach, while the double (bosonic + fermionic) PV subtraction is required in the case of LFD.

III. FERMION ELECTROMAGNETIC VERTEX

We can now proceed to the calculation of the spin-1/2 fermion elastic EMV, Γ , which is connected with the

matrix element of the electromagnetic current J by the relation

$$J = e u(p^0) \Gamma u(p); \quad (35)$$

where e is the physical electromagnetic coupling constant, p and p^0 are the initial and final on-mass-shell fermion four-momenta ($p^0^2 = p^2 = m^2$). Assuming P -, C -, and T -parity conservation, Γ is defined by two form factors depending on the momentum transfer squared $Q^2 = (p^0 - p)^2$:

$$\Gamma u = u^0 F_1(Q^2) + \frac{iF_2(Q^2)}{2m} \not{q} u; \quad (36)$$

We omit for simplicity the bispinor arguments and denoted $q = p^0 - p$, $\not{q} = i(\gamma_4 - \gamma_5) = 2$.

We consider here, as in Sec. II, the Yukawa model which takes into account interaction of fermions with scalar bosons, while the EMV "dressing" due to fermion-photon interactions is neglected. The fermion-boson interaction is treated perturbatively, up to terms of order g^2 .

At that order, the EMV must be renormalized. The standard renormalization recipe consists in the subtraction $\Gamma^{ren} = Z_1 \Gamma$ with the constant Z_1 found from the requirement $u(p) \Gamma^{ren} u(p) = u(p) \Gamma u(p)$. This leads

to the following well-known expressions for the renormalized form factors:

$$F_1^{\text{ren}}(Q^2) = 1 + F_1(Q^2) - F_1(0); \quad F_2^{\text{ren}}(Q^2) = F_2(Q^2); \quad (37)$$

We shall follow the same ideology that we exposed above for the self-energy: independent calculations of the EM V are performed, within covariant LFD and the Feynman approach, both for non-invariant and invariant regularization. However, in contrast to the self-energy case, the use of rotationally non-invariant cutoffs results in the appearance of new structures (and form factors) in the EM V, even if one starts from the standard four-dimensional Feynman expression. By this reason, the renormalization of the two physical form factors only, as prescribed by Eqs. (37), is not enough to get the full renormalized EM V.

A. Calculation in light-front dynamics

1. Light-front interaction Hamiltonian involving electromagnetic interaction

Before going over to the consideration of the EM V in covariant LFD, one should derive the interaction Hamiltonian which involves both fermion-boson and fermion-photon interactions. Although all the diagrams calculated below are generated by the graph technique rules formulated in Ref. [1], this is another way to explain their origin.

We will not give here a detailed derivation. The corresponding procedure is exposed in Ref. [7]. We derived there the LF Hamiltonian describing a system of interacting fermion and massless vector boson fields. This expression holds also for a fermion-photon system. When the photon field is taken in the Feynman gauge, the Hamiltonian in Schrodinger representation has the form

$$H^{\text{int}}(\mathbf{x}) = e \bar{\psi} + e^2 \bar{\psi} \frac{\not{\partial}}{2i(\not{\partial})} \psi; \quad (38)$$

where ψ and A are the free fermion and photon fields, respectively, and the operator $\not{\partial} = (i\partial_{\mu})$ in coordinate space acts on the coordinate along the four-vector $\not{\partial}$ (for convenience we denote it for a momentum as \not{x} , since $\not{\partial}$ in standard LFD has only the minus-component):

$$\frac{1}{i\partial_{\mu}} f(\mathbf{x}) = \exp \left[\frac{\hbar}{i\partial_{\mu}} \int \frac{e^{-i\mathbf{y}\cdot\mathbf{x}}}{n} \frac{1}{i\partial_{\mu}} \exp \left[\frac{\hbar}{i\partial_{\mu}} \int \frac{e^{-i\mathbf{y}\cdot\mathbf{x}}}{n} A f(\mathbf{x}) \right] \right] \quad (39)$$

and $\not{\partial} = (i\partial_{\mu})$ is the free reversal derivative operator:

$$\frac{1}{i\partial_{\mu}} f(\mathbf{x}) = \frac{i}{4} \int_{\mathbb{Z}} dy_{\mu} (\mathbf{x} - \mathbf{y}) f(\mathbf{y}); \quad (40)$$

where $\text{sgn}(x)$ is the sign function. The operators $\not{\partial}$ inside the exponents act on the functions $\int \frac{e^{-i\mathbf{y}\cdot\mathbf{x}}}{n} A$ only, while

that standing between the exponents acts on all the functions to the right of it. In momentum representation, the action of the operator $\not{\partial} = (i\partial_{\mu})$ on a function $f(\mathbf{x})$ reduces to the multiplication of its Fourier transform $f(\mathbf{k})$ by the factor $\not{\partial} = (i\mathbf{k})$.

It is easy to modify the Hamiltonian (38) in order to incorporate interactions between fermions and scalar bosons. The equation of motion for the Heisenberg fermion field operator ψ , in the absence of scalar bosons, looks like $(i\partial_{\mu} - m)\psi = e\bar{\psi}$, where A is the Heisenberg photon field operator. If we introduce a scalar boson field ϕ , the equation of motion becomes $(i\partial_{\mu} - m)\psi = (e\bar{\psi} + g\phi)$. Since the latter equation of motion is obtained from the previous one by the substitution $\bar{\psi} \rightarrow \bar{\psi} + (g/e)\phi$, it is enough to make the same substitution in the Hamiltonian (38), everywhere except in the operator $\not{\partial} = (i\partial_{\mu})$ [7]. The Hamiltonian thus becomes

$$H^{\text{int}}(\mathbf{x}) = \left[\bar{\psi} + e\bar{\psi} \right] \left[\psi + e\psi \right] + \left[\bar{\psi} + e\bar{\psi} \right] \frac{\not{\partial}}{2i\partial_{\mu}} \left[\psi + e\psi \right]; \quad (41)$$

We see that the LFD interaction Hamiltonian (41) involves also, besides the usual term $\bar{\psi} \psi$ describing ordinary fermion-boson and fermion-photon interactions, the so-called contact terms which are nonlinear in the coupling constants. Note that if we expand the Hamiltonian (41) in powers of e , this expansion contains an infinite number of terms. Such a peculiarity is connected with the photon spin and with the gauge we have chosen.

In this paper, we are not interested in studying electromagnetic effects, but focus on the interaction between fermions and scalar bosons. We therefore restrict the Hamiltonian to the first order in the electromagnetic coupling constant e , neglecting the terms of order e^2 and higher. The result is

$$H^{\text{int}} = H_{fb1} + H_{fb2} + H_{em1} + H_{em2} + H_{em3}; \quad (42)$$

where

$$H_{fb1} = \bar{\psi} \psi; \quad (43a)$$

$$H_{fb2} = g^2 \bar{\psi} \frac{\not{\partial}}{2i\partial_{\mu}} \psi; \quad (43b)$$

$$H_{em1} = e \bar{\psi} \not{\partial} \psi; \quad (43c)$$

$$H_{em2} = eg \bar{\psi} \left[\frac{\not{\partial}}{2i\partial_{\mu}} \phi + \phi \frac{\not{\partial}}{2i\partial_{\mu}} \right] \psi; \quad (43d)$$

$$H_{em3} = \frac{1}{2} eg^2 \bar{\psi} \frac{\not{\partial}}{i\partial_{\mu}} \frac{1}{i\partial_{\mu}} \int \frac{e^{-i\mathbf{y}\cdot\mathbf{x}}}{n} A \frac{\not{\partial}}{i\partial_{\mu}} \psi; \quad (43e)$$

The contact terms are H_{fb2} , H_{em2} , and H_{em3} . The operators $\not{\partial} = (i\partial_{\mu})$ inside the squared brackets act on $\int \frac{e^{-i\mathbf{y}\cdot\mathbf{x}}}{n} A$ only.

2. Light-front diagrams and their amplitudes

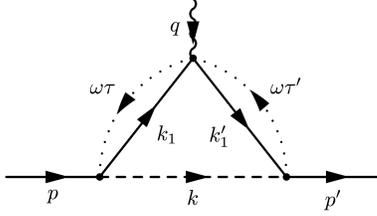

FIG. 2: Triangle LF diagram

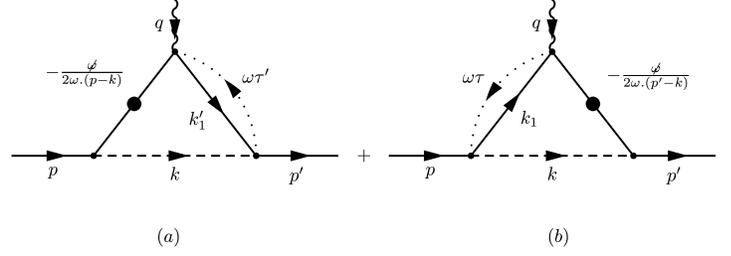

FIG. 4: Left (a) and right (b) contact terms

Since the amplitude of the process which we are interested in is proportional to \$e^2\$, we should collect together the matrix elements from the Hamiltonian (42) in the first, second and third orders of perturbation theory. It can be written schematically as

$$\langle H_{fb1}^2 H_{em1} \rangle + \langle H_{fb1} H_{em2} \rangle + \langle H_{em3} \rangle :$$

Note that although the matrix element of the sec-

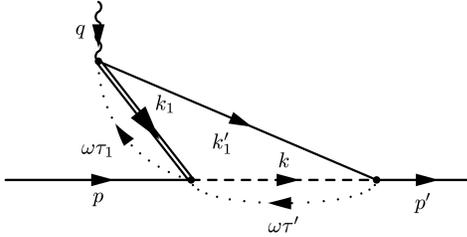

FIG. 3: Pair creation by a photon. The double solid line stands for an antifermion

ond order of perturbation theory, $\langle H_{fb1} H_{em1} \rangle$, is also of order \$e^2\$, it does not result in irreducible diagrams. The Hamiltonian (42) produces therefore the two contributions to the EMV, shown in Figs. 2{5. The triangle and pair creation diagrams are generated by $\langle H_{fb1}^2 H_{em1} \rangle$, the left and right contact terms come from $\langle H_{fb1} H_{em2} \rangle$, while $\langle H_{em3} \rangle$ is responsible for the double contact term. Applying the rules of the LFD graph technique [1] to these diagrams¹, we can find analytical expressions for the corresponding amplitudes. However, before writing them down, one should note the following. When calculating the form factors in covariant LFD, the condition $q_+ = 0$ on the momentum transfer is usually imposed (equivalent to $q_+ = q_3 + q_2 = 0$ in the

non-covariant version of LFD). It comes from the analysis of the pure scalar "EMV" (i.e., when all the particles, including the photon, are spinless), where it forbids the pair creation diagram. Indeed, since the plus-component of the pair momentum is always positive, the pair can not be created by a virtual photon with $q_+ = 0$. As a result, when $q_+ \neq 0$, the corresponding phase space volume tends to zero, and the amplitude of the pair creation diagram disappears. For systems involving fermions and/or vector photons, the amplitude of the pair creation diagram becomes infinite if q_+ exactly equals zero, since it is given by an integral with an infinitely large integrand and zero phase space volume. For this reason, one has to take $q_+ \neq 0$. We set $q_+ = \epsilon p_+$ ($\epsilon > 0$), where ϵ is a constant which we take positive, for definiteness. We will see below that for the rotationally non-invariant cut-offs discussed in Sec. II, a non-zero contribution to the EMV from the pair creation diagram survives, and moreover, it tends to infinity when $\epsilon \rightarrow 0$.

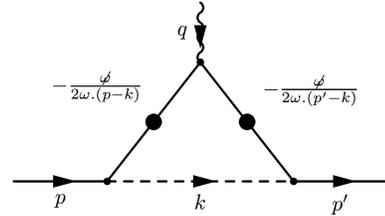

FIG. 5: Double contact term

¹ The rules incorrectly prescribe to use the theta-function $\theta(k_+)$ for the contact term. This theta-function should be removed.

We can now proceed to the calculation of the LF diagram amplitudes. The contribution of the triangle dia-

gram on Fig. 2 reads

$$\begin{aligned}
 (\text{tri}) &= \frac{g^2}{(2)^3} \int^Z (!k)^2 (k^2) d^4k \\
 &\quad (\not{p} \not{k} + \not{p} + m) [! \not{p} \not{k}] \\
 &\quad [(\not{p} \not{k} + !)^2 - m^2] \frac{d^0}{0} \\
 &\quad (\not{p} \not{k} + \not{p} + m) [! (\not{p} \not{k})] \\
 &\quad [(\not{p} \not{k} + !)^2 - m^2] \frac{d^1}{1} \quad (44) \\
 &= \frac{g^2}{(2)^3} \int^Z d^2k_? \int_{-1}^1 \frac{dx}{2x} \\
 &\quad \frac{(\not{p} \not{k} + \not{p} + m) (\not{p} \not{k} + \not{p} + m)}{2! (\not{p} \not{k})^0 2! (\not{p} \not{k})} :
 \end{aligned}$$

We have introduced here new integration LF variables $k_?$ and x in a standard fashion (see Sec. IIA 1). The singularities of the integrand at $x = 0$ and $x = 1$ are excluded by introducing an infinitesimal positive cut-off. The values of ϵ 's are found from the conservation laws imposed by the delta-functions. Namely,

$$\begin{aligned}
 2! (\not{p} \not{k}) &= \not{p} m (\not{p} \not{k}^2) \\
 &= (1-x) \frac{k_?^2 + m^2}{1-x} + \frac{k_?^2 + \epsilon^2}{x} m^2 ; \quad (45a)
 \end{aligned}$$

$$\begin{aligned}
 2! (\not{p} \not{k})^0 &= m^2 (\not{p} \not{k}^2) \\
 &= (1-x^0) \frac{k_?^2 + m^2}{1-x^0} + \frac{k_?^2 + \epsilon^2}{x^0} m^2 ; \quad (45b)
 \end{aligned}$$

where $x^0 = !k = !p x = (1-x)$, $k_?^0 = k_?$, x^0 , and ϵ is the part of the three-vector q , transversal to $!$. Note that

$$\epsilon^2 = Q^2 (1-x) - \epsilon^2 m^2 : \quad (46)$$

The formulas (45) { (46) follow from the kinematical relations listed in Appendix A.

The contribution of the pair creation diagram, Fig. 3, is given by

$$\begin{aligned}
 (\text{pair}) &= \frac{g^2}{(2)^3} \int^Z (!k)^2 (k^2) d^4k \\
 &\quad (\not{p} \not{k} + \not{p} + m) [! \not{p} \not{k}] \\
 &\quad [(\not{p} \not{k} + !)^2 - m^2] \frac{d^0}{0} \\
 &\quad (\not{p} \not{k} + \not{p} + m) (\not{p} \not{k} + \not{p} + m) [! (k \not{p})] \\
 &\quad [(\not{p} \not{k} + !)^2 - m^2] \frac{d^1}{1} :
 \end{aligned}$$

The line carrying the four-momentum k_1 corresponds to an antifermion and is described by the propagator $(m \not{k}_1) (!_1 k_1^2 - m^2)$. It is convenient to introduce

a new variable $= 0_1$, instead of $_1$:

$$\begin{aligned}
 (\text{pair}) &= \frac{g^2}{(2)^3} \int^Z \frac{d^3k}{2^k} (\not{p} \not{k} + \not{p} + m) \\
 &\quad [! \not{p} \not{k}] [(\not{p} \not{k} + !)^2 - m^2] \frac{d^0}{0} \\
 &\quad (\not{p} \not{k} + \not{p} + m) [! (k \not{p})] \\
 &\quad [(\not{p} \not{k} + !)^2 - m^2] \frac{d^1}{(0)} \quad (47) \\
 &= \frac{g^2}{(2)^3} \int^Z d^2k_? \int_{-1}^1 \frac{dx}{2x} \\
 &\quad \frac{(\not{p} \not{k} + \not{p} + m) (\not{p} \not{k} + \not{p} + m)}{2! (\not{p} \not{k})^0 2! (\not{p} \not{k})} :
 \end{aligned}$$

The "shifted" enters the delta-function and is determined by the same formula (45a) as in other 's. We can therefore use the same kinematics. The integration over d by means of the delta-function $[(\not{p} \not{k} + !)^2 - m^2]$ brings the factor $j! (\not{p} \not{k})^j$ in the denominator. We used that $j! (\not{p} \not{k})^j = ! (\not{p} \not{k})$ inside the integration interval $1 + \epsilon < x < 1 + \epsilon$.

The contribution of the left contact term to the EM V is shown in Fig. 4 (a). The corresponding amplitude has the form

$$\begin{aligned}
 (\text{lct}) &= \frac{g^2}{(2)^3} \int^Z (!k)^2 (k^2) d^4k \\
 &\quad (\not{p} \not{k} + \not{p} + m) [! \not{p} \not{k}] \\
 &\quad [(\not{p} \not{k} + !)^2 - m^2] \frac{d^0}{0} \\
 &\quad \frac{\epsilon}{2! (\not{p} \not{k})} \quad (48) \\
 &= \frac{g^2}{(2)^3} \int^Z d^2k_? \int_{-1}^1 \frac{dx}{2x} \frac{(\not{p} \not{k} + \not{p} + m) \epsilon}{2! (\not{p} \not{k})^0 2! (\not{p} \not{k})} :
 \end{aligned}$$

For the right contact term, Fig. 4 (b), we get

$$\begin{aligned}
 (\text{rct}) &= \frac{g^2}{(2)^3} \int^Z (!k)^2 (k^2) d^4k \\
 &\quad \frac{\epsilon}{2! (\not{p} \not{k})} (\not{p} \not{k} + \not{p} + m) \\
 &\quad [! (\not{p} \not{k})] [(\not{p} \not{k} + !)^2 - m^2] \frac{d^1}{1} \quad (49) \\
 &= \frac{g^2}{(2)^3} \int^Z d^2k_? \int_{-1}^1 \frac{dx}{2x} \frac{\epsilon (\not{p} \not{k} + \not{p} + m)}{2! (\not{p} \not{k})^0 2! (\not{p} \not{k})} :
 \end{aligned}$$

Finally, the double contact term, Fig. 5, yields

$$\begin{aligned}
 (\text{2ct}) &= \frac{g^2}{(2)^3} \int^Z d^2k_? \int_{-1}^1 \frac{dx}{2x} \frac{\epsilon}{2! (\not{p} \not{k})} \frac{\epsilon}{2! (\not{p} \not{k})} : \quad (50)
 \end{aligned}$$

The full EM V is the sum of all the ve contributions (44), (47) (50). Note that the limits of integrations over dx are different in these contributions. In order to make the calculations easier, we split the whole region of possible values of x into the three sub-regions: (1) $0 < x < 1$; (2) $1 < x < 1 + \frac{1}{\beta}$; (3) $1 + \frac{1}{\beta} < x < 1 + \frac{1}{\beta} + \frac{1}{\beta}$. We then represent each of the vertices $\Gamma^{(1ct)}$ and $\Gamma^{(2ct)}$ as a sum of integrals over these integration sub-regions, removing the singularities by means of the same cut-off ϵ :

$$\Gamma^{(1ct)} = \Gamma^{(1;1ct)} + \Gamma^{(2;1ct)};$$

where

$$\Gamma^{(1;1ct)} = \frac{g^2}{64^3} \frac{1}{(\beta^2)^Z} \int_0^1 dx \frac{(\beta^0 \epsilon + \beta^0 + m) \epsilon}{x (1 + \frac{\epsilon}{x}) (1 - x)^0};$$

$$\Gamma^{(2;1ct)} = \frac{g^2}{64^3} \frac{1}{(\beta^2)^Z} \int_{1+\frac{1}{\beta}}^{1+\frac{1}{\beta}+\frac{1}{\beta}} dx \frac{(\beta^0 \epsilon + \beta^0 + m) \epsilon}{x (1 + \frac{\epsilon}{x}) (1 - x)^0};$$

and, analogously,

$$\Gamma^{(2ct)} = \Gamma^{(1;2ct)} + \Gamma^{(2;2ct)};$$

where

$$\Gamma^{(1;2ct)} = \frac{g^2}{64^3} \frac{\epsilon}{(\beta^2)^Z} \int_0^1 dx \frac{1}{x (1 + \frac{\epsilon}{x}) (1 - x)};$$

$$\Gamma^{(2;2ct)} = \frac{g^2}{64^3} \frac{\epsilon}{(\beta^2)^Z} \int_{1+\frac{1}{\beta}}^{1+\frac{1}{\beta}+\frac{1}{\beta}} dx \frac{1}{x (1 + \frac{\epsilon}{x}) (1 - x)}$$

$$+ \frac{g^2}{64^3} \frac{\epsilon}{(\beta^2)^Z} \int_{1+\frac{1}{\beta}}^{1+\frac{1}{\beta}+\frac{1}{\beta}} dx \frac{1}{x (1 + \frac{\epsilon}{x}) (1 - x)};$$

After some rearrangement of the contributions, we can represent the full EM V as

$$\Gamma^{(1ct)} + \Gamma^{(2ct)} + \Gamma^{(3ct)} \quad (51)$$

with

$$\Gamma^{(A)} = \Gamma^{(tri)} + \Gamma^{(1;1ct)} + \Gamma^{(1ct)} + \Gamma^{(2;2ct)} + \Gamma^{(2ct)} + \Gamma^{(0)}; \quad (52a)$$

$$\Gamma^{(B)} = \Gamma^{(pair)} + \Gamma^{(2;1ct)} + \Gamma^{(1)}; \quad (52b)$$

$$\Gamma^{(C)} = \Gamma^{(2;2ct)} + \Gamma^{(0)} + \Gamma^{(1)}; \quad (52c)$$

The two new integrals,

$$\Gamma^{(0)} = \frac{g^2}{64^3} \frac{\epsilon}{(1 + \frac{\epsilon}{\beta})} \frac{\epsilon}{(\beta^2)^Z} \int_0^1 dx \frac{1}{x}; \quad (53a)$$

$$\Gamma^{(1)} = \frac{g^2}{64^3} \frac{\epsilon}{(\beta^2)^Z} \int_{1+\frac{1}{\beta}}^{1+\frac{1}{\beta}+\frac{1}{\beta}} dx \frac{1}{x (1 + \frac{\epsilon}{x})} \quad (53b)$$

have been introduced in order to make the integrands of $\Gamma^{(A)}$ and $\Gamma^{(B)}$ non-singular in x, although each term on the right-hand sides of Eqs. (52a) and (52b) contains logarithmic divergencies either at $x = 0$ or at $x = 1$, or at $x = 1 + \frac{1}{\beta}$.

Taking the sums (52a) and (52b), we easily find

$$\Gamma^{(A)} = \frac{g^2}{16^3} \int_0^1 dx \frac{(\beta^0 \epsilon + \beta^0 + m) (\beta^0 \epsilon + \beta^0 + m) \epsilon}{x (2 - 2\beta^0 k) \ell (2\beta^0 k) 4(1 + \frac{\epsilon}{\beta}) (\beta^2)^Z}; \quad (54a)$$

$$\Gamma^{(B)} = \frac{g^2}{64^3} \int_{1+\frac{1}{\beta}}^{1+\frac{1}{\beta}+\frac{1}{\beta}} dx \frac{(\beta^0 \epsilon + \beta^0 + m) (\beta^0 \epsilon + \beta^0 + m) \epsilon}{x (1 + \frac{\epsilon}{x}) (x - 1)^0 (\beta^2)^Z}; \quad (54b)$$

Since the regularization in x is no more required, we set $\epsilon = 0$.

The remaining part of the EM V, $\Gamma^{(C)}$, is given by a

sum of regularized integrals:

$$\begin{aligned}
 {}^{(C)} = & \frac{g^2}{64} \frac{\mathfrak{g}}{3} \frac{\mathfrak{g}}{(! \mathfrak{p}^{\mathfrak{b}})} \int d^2 k_{\mathfrak{z}} \int_0^1 \frac{1}{1+x} \frac{dx}{x} \\
 & + \int_0^1 \frac{1}{1+x} \int_0^{1+x} \frac{dx}{x(1-x)} \\
 & + \int_0^{1+x} \frac{1}{1+x} \int_0^x \frac{dx}{x(1-x)(1-x)} :
 \end{aligned} \quad (55)$$

3. Electromagnetic form factors

We represent the EM V via the following decomposition:

$$\begin{aligned}
 u^0 u = u^0 F_1 + \frac{iF_2}{2m} \not{q} \\
 + B_1 \frac{\mathfrak{g}}{! \mathfrak{p}} (\not{p} + \not{p}^0) \not{2} + B_2 \frac{m!}{! \mathfrak{p}} + B_3 \frac{m^2 \mathfrak{g}!}{(! \mathfrak{p}^{\mathfrak{b}})} u;
 \end{aligned} \quad (56)$$

which is similar, although not identical, to the one used in Ref. [20]. We shall come back to this difference in Sec. IV. The decomposition is determined by the ve^2 form factors $F_{1,2}$, B_{1-3} . We shall call $F_{1,2}$ the physical form factors, in contrast to the non-physical ones, B_{1-3} , which must be absent in the physically observed EM V. The appearance of the three extra form factors is a property of LFD. Note that they appear in standard non-covariant LFD as well, but in this approach they can not be separated out from the physical form factors, and an illusion may occur that the EM V structure is determined, according to Eq. (36), by the two form factors, as in the Feynman case. This is however not so, because the electromagnetic current operator in LFD has ve independent matrix elements, not two. One may argue that even if each particular LF diagram produces a contribution of the form (56) to the EM V, the extra three structures disappear (i.e., one has $B_{1-3} = 0$) after summing up all the contributions, at least in a given order of perturbation theory. It would be so if the amplitudes of the LF diagrams were given by convergent integrals, which happens for the pure scalar case (scalar bosons plus scalar "photon" and no fermions). For systems involving fermions, however, the amplitudes strongly diverge. Their regularization, as will be shown below, may give rise to the appearance of extra (!-dependent) spin structures in the perturbative and non-perturbative regularized EM V's. In this sense the situation is analogous to the case of the fermion selfenergy discussed in the previous section.

The procedure to calculate the form factors is quite similar to that exposed in Ref. [20]. We define the matrix

$$O = \frac{(\mathfrak{p}^0 + m) (\not{p} + m)}{4m^2} \quad (57)$$

and the following contractions:

$$\begin{aligned}
 c_1 &= \text{Tr} f O \not{g}; \\
 c_2 &= \frac{iq}{2m} \text{Tr} f O \not{g}; \\
 c_3 &= \frac{(\not{p} + \not{p}^0)}{! \mathfrak{p}} \text{Tr} f O \mathfrak{g}; \\
 c_4 &= \frac{m!}{! \mathfrak{p}} \text{Tr} f O \not{g}; \\
 c_5 &= \frac{m^2!}{(! \mathfrak{p}^{\mathfrak{b}})} \text{Tr} f O \mathfrak{g};
 \end{aligned} \quad (58)$$

Now, using Eq. (56), we can get the following relations between the form factors and the quantities c_{1-5} :

$$\begin{aligned}
 c_1 &= (2-4) F_1 - 6 F_2 + 2(4+) B_1 \\
 &+ (2+) B_2 + 2(1+) B_3; \\
 c_2 &= 6 F_1 + 2(2-) E_2 - 2(4-) B_1 \\
 &+ (2+) B_2 + \frac{2}{2} B_3; \\
 c_3 &= 2(2+) F_1 - 2(2+) E_2 \\
 &+ 4[2(1+) + B_1 + (2+) ^2 B_2 \\
 &+ 2(2+)(1+) B_3]; \\
 c_4 &= (2+) [F_1 - E_2 + B_1]; \\
 c_5 &= 2(1+) F_1 - \frac{2}{2} F_2 + 2(1+) B_1;
 \end{aligned} \quad (59)$$

where $\mathfrak{g} = Q^2 = (4m^2)$. Solving the system of linear equations (59) with respect to $F_{1,2}$ and B_{1-3} , we express them through c_{1-5} . These expressions are lengthy and we do not give them here. Then, substituting the formulas (54), (55) for ${}^{(A)}$, ${}^{(B)}$, and ${}^{(C)}$ into Eq. (57), calculating the traces (58), and expressing the scalar products of the four-vectors p, p^0, k , and $!$ through the two-dimensional vectors $k_{\mathfrak{z}}$, $!$, and the scalars x , $!$, we cast each form factor in the form of a three-dimensional integral over $d^2 k_{\mathfrak{z}} dx$. The expressions for the scalar products through the integration variables and the momentum transfer are given in Appendix A.

4. Regularization with rotationally non-invariant cut-offs

We give here the final expressions for the form factors found by using the rotationally non-invariant cut-offs \mathfrak{z} and $!$ imposed on the variables $k_{\mathfrak{z}}$, $!$ and x . As we said above, the vertex functions ${}^{(A)}$ and ${}^{(B)}$ do not require to introduce a cut-off in x . As far as ${}^{(C)}$ is concerned, it is represented by a sum of integrals, each requiring regularization and thus depending on $!$. However, as can

² The coincidence of the number of form factors with the number of LF diagrams is, of course, by chance.

be established by direct integration in Eq. (55), the sum itself has a finite limit when $\epsilon \rightarrow 0$:

$$(c) = \frac{g^2}{32} \frac{2}{m^2} \frac{\log(1 + \frac{m}{Q})}{(1 + \frac{m}{Q})} \frac{6!}{(1!)^6}; \quad (60)$$

We therefore remain with the cutoff ϵ only. Note that the mutual cancellation of the terms singular in ϵ , which happens for the full EM V, is connected with rather weak (logarithmic) divergence of the corresponding integrals, so that the cutoff ϵ is enough to make them finite. The same took place in the fermion self-energy case (see Sec. IIA 2). As we shall see below [Eq. (C11) in Appendix C], the quadratically divergent term $6! \frac{2}{m^2}$ results also from (B) (but not from (A)) and cancels in the sum with (c) .

The details of calculations of all the contributions (A;B;C) are given in Appendix C. Adding all them together, we arrive at the following final result for the form factors:

$$F_1 = \frac{g^2}{16} \frac{2}{m^2} \log \frac{m}{Q} + \frac{g^2}{4} \frac{2}{m^2} \log \frac{m}{Q} - \frac{7}{8} + \frac{g^2 Q^2}{24} \frac{2}{m^2} \log \frac{m}{Q} - \frac{9}{8} + O(Q^4); \quad (61a)$$

$$F_2 = \frac{3g^2}{16} \frac{2}{m^2} - \frac{g^2 Q^2}{32} \frac{2}{m^2} + O(Q^4); \quad (61b)$$

$$B_1 = \frac{g^2}{64} \frac{2}{m^2}; \quad (61c)$$

$$B_2 = \frac{g^2}{32} \frac{2}{m^2}; \quad (61d)$$

$$B_3 = \frac{g^2 (m^2 - Q^2)}{16} \frac{2}{m^2} \log \frac{m}{Q} + \frac{g^2}{32} \frac{2}{m^2} \frac{Q^2}{m^2} + \frac{2}{m^2} \log \frac{m}{Q} + 1; \quad (61e)$$

Note that the terms $\log \frac{m}{Q}$ cancel in the form factors B_1 and B_2 . These form factors are finite and do not depend on any cutoff ϵ , in contrast to B_3 which does not have a finite limit when $\epsilon \rightarrow 1$. As we have already mentioned, neither of the form factors depend on the cutoff ϵ . At the same time, the amplitude of each of the LF diagrams shown in Figs. 2{5, diverges like $\frac{2}{m^2} \log \frac{m}{Q}$. It means that the senior divergent terms $\frac{2}{m^2} \log \frac{m}{Q}$ and $\frac{2}{m^2}$ cancel after the incorporation of all the LF diagrams. However, the form factors B_{1-3} which must be absent in the physical EM V remain non-zero values. The same happened for the θ term in the full self-energy, Eq. (7).

We also see that B_3 has a pole at $Q = 0$. One cannot set here $Q^2 = 0$, since it is impossible to keep $\text{xed } \frac{m}{Q} = (1/q) = (1/p)$ when $q \rightarrow 0$. More precisely, since $Q^2 = 0$, from Eq. (46) we have $Q^2 = \frac{2m^2}{1+}$. However, nothing prevents us to take $\epsilon \rightarrow 0$ at $\text{xed } Q^2$. As the inspection shows, the singular term $1 =$ in B_3 results from (pair) , Eq. (47).

The standard renormalization procedure (37) affects

the form factor F_1 only, so that

$$F_1^{\text{ren}} = 1 - \frac{g^2 Q^2}{24} \frac{2}{m^2} \log \frac{m}{Q} - \frac{9}{8} + O(Q^4); \quad (62)$$

The cutoff-dependent term $\log(\frac{m}{Q})$ cancels, as it should. The renormalized form factor F_2^{ren} coincides with F_2 , Eq. (61b). It is important to note that in order to eliminate the three extra form factors B_{1-3} , one should introduce new ϵ -dependent counterterms into the interaction Hamiltonian. Since B_3 non-trivially depends on q through $Q^2 = \frac{m^2}{q^2}$ and $\frac{m}{Q} = \frac{m}{p}$, its decomposition in powers of q contains an infinite number of terms. Therefore, to eliminate B_3 we need an infinite number of local counterterms, for this particular type of regularization.

5. Invariant Pauli-Villars regularization

We can now calculate the form factors within LFD, but using the invariant PV regularization instead of the LF cutoffs ϵ and ϵ' .

Regularization by a PV boson. We start with the regularization by one PV boson only. Since each of the LF diagrams contains one bosonic propagator, this regularization reduces to a simple subtraction

$$F^{\text{PV};b} = F(Q^2; m; \epsilon) - F(Q^2; m; \epsilon_1);$$

As before, F denotes any of the form factors F_i or B_i . In the limit of large ϵ_1 we have

$$F_1(Q^2; m; \epsilon_1) = \frac{g^2}{16} \frac{2}{m^2} \log \frac{m}{\epsilon_1} - \frac{g^2}{16} \frac{2}{m^2} \log \frac{1}{m} - \frac{1}{4};$$

$$F_2(Q^2; m; \epsilon_1) = 0;$$

for arbitrary finite Q^2 . Subtracting these expressions from those given by Eqs. (61a) and (61b), respectively, we get

$$F_1^{\text{PV};b} = \frac{g^2}{16} \frac{2}{m^2} \log \frac{1}{m} + \frac{g^2}{4} \frac{2}{m^2} \log \frac{m}{Q} - \frac{15}{16} + \frac{g^2 Q^2}{24} \frac{2}{m^2} \log \frac{m}{Q} - \frac{9}{8} + O(Q^4); \quad (63a)$$

$$F_2^{\text{PV};b} = \frac{3g^2}{16} \frac{2}{m^2} - \frac{g^2 Q^2}{32} \frac{2}{m^2} + O(Q^4); \quad (63b)$$

In spite of the fact that Eq. (63a) differs from Eq. (61a), both equations lead to the same renormalized form factor F_1^{ren} , Eq. (62). The renormalized physical form factors obtained for the invariant and non-invariant types of regularization do therefore coincide.

Concerning the non-physical form factors, the situation is quite different. Since B_{1-3} were calculated for arbitrary ϵ , we find from Eqs. (61c)-(61e):

$$B_1^{\text{PV};b} = B_2^{\text{PV};b} = 0; \quad (64a)$$

$$B_3^{PV;b} = \frac{g^2 \left(\frac{2}{1} \right)^2}{16^2 m^2 (1 +)} \log \frac{?}{m} + \frac{g^2}{32^2 m^2} \frac{2}{1} \frac{2}{2} \log \frac{m}{m} + 2^2 \log \frac{1}{m} : \quad (64b)$$

The formulas (63) are valid for $! = 0$ and $1! = 1$, while Eqs. (64) hold for arbitrary and 1 . The non-physical form factors $B_{1;2}$ turned into zero, while $B_3^{PV;b} \notin 0$ and still diverges logarithmically.

Regularization by one PV boson plus one PV fermion. Since the PV regularization by one boson only does not cancel the form factor B_3 , we have to introduce in addition a PV fermion. In that case, no contact terms appear at all, and the only diagrams which contribute to the EMV are the triangle (Fig. 2) and pair creation (Fig. 3) diagrams. Each of them contains two fermion propagators, both being subject to the PV regularization. For this reason we need to know the vertex with different internal fermions. We denote the masses of these fermions by m_i and m_{i^0} , with the indices i and i^0 being either 0 or 1. Let $m_0 = m$ and m_1 be the physical and PV fermion masses, respectively. Analogously, we denote the physical and PV boson masses by Q_0 and Q_1 .

The PV regularized EMV is defined by

$$B_3^{PV;b+f} = \sum_{i,i^0;j=0}^{X^1} (1)^{i+i^0+j} B_3^{(N)PV;b} (m_i; m_{i^0}; j);$$

where the notation $B_3^{(N)PV;b} (m_i; m_{i^0}; j)$ stands for the corresponding initial EMV calculated for the internal particles with the masses m_i , m_{i^0} , and Q_j . The quantity $B_3^{(N)PV;b} (m_i; m_{i^0}; j)$ itself is given by a sum of Eqs. (54), changing everywhere

$$\begin{aligned} \not{p} & \rightarrow \not{p} + m_1; & \not{p} & \rightarrow \not{p} + m_i; \\ \not{p}^0 & \rightarrow \not{p}^0 + m_1; & \not{p}^0 & \rightarrow \not{p}^0 + m_{i^0}; \\ & & & \rightarrow \frac{m_i^2}{2!} \frac{(\not{p} - \not{k})^2}{(\not{p} - \not{k})}; \\ 0 & \rightarrow \frac{m_{i^0}^2}{2!} \frac{(\not{p}^0 - \not{k})^2}{(\not{p} - \not{k})}; \end{aligned}$$

and $! = j$. The vertex $\Gamma^{(C)}$, Eq. (55), turns into zero already by the boson PV regularization and does not contribute to the PV regularized form factors.

It can be shown that we do not need to introduce the PV fermion to regularize the form factors $F_{1;2}$ and $B_{1;2}$. In other words, in the limit $m_1 \rightarrow 1$ we would obtain the same formulas (63) (64a) as without the PV fermion at all. So, the only thing to do is to calculate $B_3^{PV;b+f}$. This calculation is in principle quite similar to that performed above, but the algebra is more lengthy. We represent $B_3^{PV;b+f}$ as follows:

$$B_3^{PV;b+f} = \sum_{i,i^0=0}^{X^1} (1)^{i+i^0} \sum_{N=A;B}^X B_3^{(N)PV;b} (m_i; m_{i^0}); \quad (65)$$

where

$$B_3^{(N)PV;b} (m_i; m_{i^0}) = \sum_{j=0}^{X^1} (1)^j B_3^{(N)} (m_i; m_{i^0}; j) \quad (66)$$

and $B_3^{(N)} (m_i; m_{i^0}; j)$ is found through the vertex $\Gamma^{(N)} (m_i; m_{i^0}; j)$. Though the order of summations in Eqs. (65) and (66) does not matter, it is convenient to calculate first $B_3^{(N)PV;b} (m_i; m_{i^0})$, separately for the two vertices, then add the results, and finally sum over the PV fermion indices. Omitting rather tiresome manipulations, we give here the expressions for the functions $B_3^{(N)PV;b} (m_i; m_{i^0})$, in order to see the details of the cancellations:

$$B_3^{(A)PV;b} (m_i; m_{i^0}) = \frac{g^2 \left(\frac{2}{1} \right)^2 (2 +)}{16^2 m^2 (1 +)^2} \log \frac{?}{m} + \frac{g^2}{32^2 m^2} \frac{2}{1} \log \frac{1}{m} + 2^2 \log \frac{m}{m} - 3 \left(\frac{2}{1} \right)^2 + R (m_i; m_{i^0}); \quad (67a)$$

$$B_3^{(B)PV;b} (m_i; m_{i^0}) = \frac{g^2 \left(\frac{2}{1} \right)^2}{16^2 m^2 (1 +)^2} \log \frac{?}{m} + \frac{g^2 \left(\frac{2}{1} \right)^2}{16^2 m^2} R (m_i; m_{i^0}); \quad (67b)$$

where

$$R (m_i; m_{i^0}) = \frac{g^2 \left(\frac{2}{1} \right)^2}{64^2 m^2 Q^2} (m_i^2 - m_{i^0}^2) \log \frac{m_i^2}{m_{i^0}^2} + 2Q^2 \log \frac{m_i m_{i^0}}{m^2} + s_Q \log \frac{(m_i^2 - m_{i^0}^2)^2}{(m_i^2 - m_{i^0}^2)^2} \frac{(Q^2 - s_Q)^2}{(Q^2 + s_Q)^2}$$

and $s_Q = \frac{p}{m_i^4} \sqrt{2m_i^2(m_{i0}^2 - Q^2) + (m_{i0}^2 + Q^2)^2}$. Both contributions (67) are rather complicated functions depending on the physical and PV masses, as well as on Q^2 . In their sum, however, the dependence on the fermion mass m_1 and on Q^2 drops out completely, and for $N=A; B_3^{(N)PV;b}(m_i; m_{i0})$ we arrive at the same expression (64b) found previously without any fermion PV regularization. The final summation over the fermion PV indices, as prescribed by Eq. (65), turns B_3 into zero:

$$B_3^{PV;b+ f} = 0; \quad (68)$$

We can thus formulate the main results of this section: the full cancellation of the three non-physical form factors is achieved by the double (i.e., bosonic + fermionic) PV regularization, whereas the single boson PV regularization cancels only two of the three non-physical form factors. The renormalized physical form factors obtained by using the PV regularization (both single and double) coincide with those calculated through the rotationally non-invariant cut-offs.

B. Calculation in the four-dimensional Feynman approach

The amplitude of the Feynman triangle diagram which determines the EMV in the given order of perturbation theory is

$$= \frac{ig^2}{(2)^4} \int d^4k \frac{1}{[k^2 - m^2 + i0]} \frac{(\not{p} - \not{k} + m)(\not{p} - \not{k} + m)}{[(p - k)^2 - m^2 + i0][(p^0 - k)^2 - m^2 + i0]}; \quad (69)$$

where $p^2 = p^{02} = m^2$. As we shall see, the spin structure of the Feynman EMV depends on how it is regularized, in contrast to the self-energy, Eq. (19). In order to avoid overloading the formulas by additional indices indicating the type of the cut-offs, we use in this section the same notations for the Feynman EMV and the form factors as for the LFD ones.

1. Regularization with rotationally non-invariant cut-offs

As we did for the self-energy, Sec. IIB 1, we first find the form factors by integrating the Feynman amplitude (69) in terms of the LF variables restricted by the transverse and longitudinal cut-offs. We shall see that such a procedure generates extra (non-physical) form factors B_{1-3} [see Eq. (56)], in a very similar way as the use of the LFD rules.

Rewriting the integrand in Eq. (69) through the plus-, minus-, and transverse components of the four-vector k ,

we get

$$= \frac{ig^2}{32} \int d^2k_T dk_+ dk_- \frac{(\not{p}^0 - \not{k} + m)}{[(p_+^0 - k_+)^0 (p^0 - k) (p_-^0 - k_-)^2 - m^2 + i0]} \frac{(\not{p} - \not{k} + m)}{[(p_+ - k_+)(p - k) (p_- - k_-)^2 - m^2 + i0]} \frac{1}{[k_+ k_- k_T^2 - m^2 + i0]}; \quad (70)$$

We take the reference frame where $p = 0$. We then choose $p_+ = p_+^0$. The latter condition is equivalent, in the language of covariant LFD, to $(! q) = (! p) = 0$. In our LFD calculation of the form factors in Sec. IIIA, we initially kept $!$ to be non-zero and went over to the limit $! \rightarrow 0$ after summing up all the LF contributions. A smooth limit $! \rightarrow 0$ was important in the LFD framework, since the amplitudes of different diagrams shown in Figs. 2(5) depend on $!$. The Feynman amplitude (69) is well-defined for any values of its arguments p and p^0 , in particular, for $p_+ = p_+^0$. We can therefore safely set $p_+ = p_+^0 = 0$ from the very beginning.

Similarly to Eq. (22) for the self-energy, we represent the full EMV as a sum of the two terms:

$$^{(p+a)} + ^{(zm)}; \quad (71)$$

corresponding to the "normal" contribution and the zero modes, respectively.

Like the self-energy case, the "normal" part $^{(p+a)}$ is determined by the sum of the pole and arc contributions. It is calculated in Appendix D, Sec. D 2. The result reads

$$^{(p+a)} = \frac{g^2}{16} \int d^2k_T \int_0^1 \frac{dx}{x} \frac{(\not{p}^0 - \not{k} + m)(\not{p} - \not{k} + m)}{((2 - 2p^0 - k)^2 - 2p - k) \ell} \frac{\not{p} \not{p}}{4(! \not{p})}; \quad (72)$$

Comparing the right-hand sides of Eq. (72) for $^{(p+a)}$ and Eq. (54a) for the part $^{(A)}$ of the EMV calculated within LFD, we see that they exactly coincide with each other at $= 0$:

$$^{(p+a)} = ^{(A)}_{=0}; \quad (73)$$

We have already encountered a similar situation above, in Sec. IIB 1, where it was shown that the pole plus arc contribution to the Feynman expression for the self-energy exactly coincided with the full LFD self-energy [see Eq. (24)]. Evidently, the vertex $^{(p+a)}$ can be also represented via form factors, in the form of the decomposition (56), but with its "own" form factors $F_{1;2}^{(p+a)}$, $B_{1-3}^{(p+a)}$. Form factors for $^{(A)}$ were found in Appendix C. Due to the identity (73), in order to derive the form factors $F_{1;2}^{(p+a)}$ and $B_{1-3}^{(p+a)}$, we can make use of Eq. (C 2) with

the coefficients from Eqs. (C7)-(C9), taken at $\epsilon = 0$. We thus find

$$F_1^{(p+a)} = \frac{g^2}{16^2} \log \frac{m^2}{m} + \frac{g^2}{4^2} \log \frac{m}{m} - \frac{7}{8} + \frac{g^2 Q^2}{24^2 m^2} \log \frac{m}{m} - \frac{9}{8} + O(Q^4); \quad (74a)$$

$$F_2^{(p+a)} = \frac{3g^2}{16^2} - \frac{g^2 Q^2}{32^2 m^2} + O(Q^4); \quad (74b)$$

$$B_1^{(p+a)} = \frac{g^2}{16^2} \log \frac{m^2}{m} - \frac{g^2}{64^2} + \frac{g^2}{16^2} f'(Q^2); \quad (74c)$$

$$B_2^{(p+a)} = \frac{g^2}{8^2} \log \frac{m^2}{m} - \frac{g^2}{32^2} - \frac{g^2}{8^2} f'(Q^2); \quad (74d)$$

$$B_3^{(p+a)} = \frac{g^2}{32^2 m^2} (6m^2 - 4^2 + Q^2) \log \frac{m^2}{m} + \frac{g^2}{32^2 m^2} (2^2 - 2 \log \frac{m}{m} + 1 - (4m^2 - 2^2 + Q^2) f'(Q^2)); \quad (74e)$$

where the function $f'(Q^2)$ is given by Eq. (C10). Note that $f'(0) = 0$. As before, the form factors $F_{1;2}^{(p+a)}$ are calculated for $\epsilon > 0$ and decomposed in powers of Q^2 , whereas $B_{1;3}^{(p+a)}$ are exact in this sense.

The zero-mode contribution $^{(zm)}$ is calculated in Appendix D, Sec. D3. The expression for $^{(zm)}$ is given by Eq. (D21). We represent it in the form of decomposition (56). Then the form factors in this decomposition have the form

$$F_1^{(zm)} = 0; \quad (75a)$$

$$F_2^{(zm)} = 0; \quad (75b)$$

$$B_1^{(zm)} = \frac{g^2}{16^2} \log \frac{m^2}{m} + \frac{g^2}{16^2} f'(Q^2); \quad (75c)$$

$$B_2^{(zm)} = \frac{g^2}{8^2} \log \frac{m^2}{m} + \frac{g^2}{8^2} f'(Q^2); \quad (75d)$$

$$B_3^{(zm)} = \frac{g^2}{32^2 m^2} (6m^2 - 4^2 + Q^2) \log \frac{m^2}{m} + \frac{g^2}{32^2} \frac{g^2}{32^2 m^2} (2^2 - 2 \log \frac{m}{m} + 1 - (4m^2 - 2^2 + Q^2) f'(Q^2)); \quad (75e)$$

The final expressions for the form factors are given by the sum of the corresponding quantities from Eqs. (74)

and (75):

$$F_1 = \frac{g^2}{16^2} \log \frac{m^2}{m} + \frac{g^2}{4^2} \log \frac{m}{m} - \frac{7}{8} + \frac{g^2 Q^2}{24^2 m^2} \log \frac{m}{m} - \frac{9}{8} + O(Q^4); \quad (76a)$$

$$F_2 = \frac{3g^2}{16^2} - \frac{g^2 Q^2}{32^2 m^2} + O(Q^4); \quad (76b)$$

$$B_1 = \frac{g^2}{64^2}; \quad (76c)$$

$$B_2 = \frac{g^2}{32^2}; \quad (76d)$$

$$B_3 = \frac{g^2}{32^2}; \quad (76e)$$

The expressions for $B_{1;3}$ are exact, i.e., these formulas are valid for any Q^2 and m . That is, the Q^2 -dependence coming from $B_{1;3}^{(p+a)}$, Eqs. (74c)-(74e), as well as the m -dependent terms are exactly canceled by the corresponding zero mode contributions $B_{1;3}^{(zm)}$. The form factors $F_{1;2}$ and $B_{1;2}$ are the same as those obtained from the LFD diagrammatic approach, in Eqs. (61), while B_3 's in Eqs. (61e) and (76e), are different. Moreover $B_{1;3}$ are not zeroes, though we started from the Feynman expression for the EM V , which initially had no any relation to the light front (i.e., to the four-vector!). We will discuss this situation in more detail below, in Sec. IV.

2. Invariant regularization

To complete our analysis, we give here the form factors obtained from Eq. (69) by using an invariant regularization of the divergent integral over d^4k . The standard recipe consists in using the Feynman parametrization, then making the Wick rotation and imposing a cut-off Λ^2 on the modulus of the Euclidean four-momentum squared, similarly to how it has been done in Sec. IIB2. After that, identifying the structure of the EM V (69) with the decomposition (36), we reproduce the well-known result:³

$$F_1 = \frac{g^2}{32^2} \log \frac{\Lambda^2}{m^2} + \frac{g^2}{4^2} \log \frac{m}{m} - \frac{15}{16} + \frac{g^2 Q^2}{24^2 m^2} \log \frac{m}{m} - \frac{9}{8} + O(Q^4); \quad (77a)$$

$$F_2 = \frac{3g^2}{16^2} - \frac{g^2 Q^2}{32^2 m^2} + O(Q^4); \quad (77b)$$

Eq. (77b) exactly coincides with Eq. (76b) obtained for the rotationally non-invariant cut-off. The for-

³ $F_2(Q^2 = 0)$ is an anomalous magnetic moment. Introducing the coupling constant $e = g^2 = (4)$, we get in the Yukawa model: $F_2(0) = 3 = (4)$ that differs by a factor of $3=2$ from the QED value $= (2)$.

mulas (77a) and (76a) differ by a constant (i.e., Q^2 -independent) part. The corresponding form factors F_1^{ren} however also coincide after the renormalization (37).

In principle, one might identify the structure of the Feynman EM V (regularized by means of an invariant cutoff) with the LF decomposition (56) containing ν form factors. In this case the formulas (77) would be found for $F_{1,2}$, while one would arrive at the evident result $B_{1,3} = 0$ for the other form factors.

The regularization of the EM V (69) by means of one PV boson results in the same formulas (77), changing ν^2 to $\frac{2}{1}$.

IV. DISCUSSION

We have shown above that the perturbative spin-1/2 fermion self-energy and the EM V calculated in LFD depend on the orientation of the LF plane, when the traditional regularization in terms of the transverse and longitudinal cutoffs is applied to the corresponding amplitudes. This dependence reveals itself in the appearance of extra spin structures in the decompositions of the self-energy and the EM V in invariant amplitudes. In covariant LFD on the plane $\not{x} = 0$ with $\not{\lambda} = 0$, it is conveniently parameterized through the four-vector $\not{\lambda}$. The corresponding decompositions for the self-energy and the EM V are given by Eqs. (7) and (56), respectively. The structure of the LF self-energy is characterized by the three scalar functions A , B , and $C = C(p^2) + C_{fc}$, instead of the two usual ones, while the on-energy-shell EM V contains ν form factors, the two standard $F_{1,2}$ and the three extra, $B_{1,3}$, ones.

Performing calculations of the self-energy by integrating the Feynman amplitude written in terms of the LF variables with the same cutoffs as in LFD, we did not encounter any $\not{\lambda}$ -dependence in the final result, Eq. (29). The latter therefore does not coincide with the LFD self-energy (7). For the EM V, both methods lead to $\not{\lambda}$ -dependent structures with ν form factors. However, the EM V calculation by means of the LFD rules results in the set of form factors (61), whereas the calculation of the Feynman amplitude in terms of the LF variables gives a different set of form factors (76). Though this difference concerns the form factor B_3 only, the corresponding EM V's do not coincide nevertheless with each other.

The extra form factors do not, of course, appear when the Feynman amplitude is calculated with a spherically symmetric cutoff in four-dimensional space. This can be achieved, e.g., by imposing a direct cutoff on the Wick rotated integration variable in Euclidean space $\int d^4k = \int d^3k \int dk_4$ or by using the PV regularization. In the case of LFD, we deal with three-dimensional integration variables. Therefore, constructing rotationally invariant (i.e., $\not{\lambda}$ -independent) cutoffs which restrict a three-dimensional integration domain encounters serious difficulties since the integration domains in LFD amplitudes

differ from each other, and it is not easy to restrict them simultaneously in a self-consistent way. This is a reason why the PV regularization looks much more preferable. It is naturally generalized to LFD and allows us to remove ultra-violet divergencies in an $\not{\lambda}$ -independent way. We showed that in order to cancel completely all $\not{\lambda}$ -dependent terms in the LF self-energy and the EM V it is necessary to use the PV subtractions for both the boson and fermion propagators. Note that this cancellation occurs for arbitrary (finite) PV masses. Simultaneously, all ultra-violet divergencies disappear. After that, the regularized LFD results coincide exactly with the Feynman ones calculated with the same PV subtractions.

The physical quantities like the functions A and B in the self-energy or the form factors $F_{1,2}$ in the EM V, can be easily extracted from the corresponding amplitudes. Once we know the self-energy $\Sigma(p)$ explicitly, taking the traces

$$\begin{aligned} \text{Tr} \Sigma(p) &= 4g^2 A(p^2); \\ \text{Tr} \Sigma(p) \not{\epsilon} &= \frac{4g^2 (\not{\lambda} \not{p})}{m} B(p^2) \end{aligned}$$

allows to get $A(p^2)$ and $B(p^2)$, because the term $\not{\epsilon}$ in the self-energy (7) does not contribute to these traces. To separate the physical electromagnetic form factors $F_{1,2}$ from the non-physical ones, $B_{1,3}$, it is enough to consider the plus-component of the current (or, in terms of covariant LFD, the contraction of the current with $\not{\lambda}$) written in the form (56). Indeed, in the limit $\not{p} = \not{\lambda}^0$, p

$$u^0 + u \cdot \not{\lambda} = u^0 (\not{\lambda} \not{\lambda}) = \not{\lambda} F_1 \not{\epsilon} + \frac{iF_2}{2m} \not{\lambda} \not{q} u:$$

As we see, $B_{1,3}$ dropped out from here. This is however not always the case since the decomposition (56) is not unique. Take, for instance, the decomposition of the same EM V given in Ref. [20]:

$$\begin{aligned} u^0 + u \cdot \not{\lambda} &= u^0 \tilde{F}_1 + \frac{i\tilde{F}_2}{2m} \not{\lambda} \not{q} \\ &+ B_1 \frac{\not{\epsilon}}{\not{\lambda} \not{p}} \frac{1}{m(1+\beta)} (\not{p} + \not{p}^0) \\ &+ B_2 \frac{m \not{\lambda}}{\not{\lambda} \not{p}} + B_3 \frac{m^2 \not{\epsilon} \not{\lambda}}{(\not{\lambda} \not{\beta})} u; \end{aligned} \quad (78)$$

where $\beta = Q^2 = 4m^2$. It is easy to see that the form factors $B_{1,3}$ in Eqs. (56) and (78) are identical, while

$$\tilde{F}_1 = F_1 \frac{2B_1}{1+\beta}; \quad \tilde{F}_2 = F_2 \frac{2B_1}{1+\beta}:$$

If we now identify $\tilde{F}_{1,2}$ with the physical form factors, they will differ from $F_{1,2}$, unless $B_1 = 0$. If we used for the regularization the LF cutoffs Λ and Λ' , we would get

$B_1 = g^2 = 64^{-2}$ [see Eqs. (61c) and (76c)] and

$$F_1 = \frac{g^2}{16^{-2}} \log \frac{\Lambda^2}{m^2} + \frac{g^2}{4^{-2}} \log \frac{m}{\Lambda} - \frac{7}{8} - \frac{g^2 Q^2}{24^{-2} m^2} \log \frac{m}{\Lambda} - \frac{21}{16} + O(Q^4);$$

$$F_2 = \frac{7g^2}{32^{-2}} - \frac{5g^2 Q^2}{128^{-2} m^2} + O(Q^4);$$

$F_{1,2}$ do not coincide neither with the Feynman form factors, given by Eqs. (77) (if we identify Λ with L), nor with the LFD ones defined by Eqs. (76a) and (76b). The regularization by the PV boson kills B_1 and this ambiguity disappears. However, if the non-physical form factors are not canceled completely, the result is sensitive to the form of the EM V representation.

Although one can use the plus-component of the current (56) to extract the physical form factors in hadron phenomenology, it is not enough in many other cases, when the knowledge of the full matrix structure of the vertex is needed. For example, this occurs in LFD non-perturbative approaches, when the EM V enters as an on-energy-shell subgraph into a more complicated diagrams. In such a case, one can not simply ignore the extra spin structures, because they may contribute to observable quantities. The latter statement concerns the self-energy as well.

As our results show, the dependence on the LF plane orientation appears not only in LFD amplitudes, but also in Feynman ones, if we put the cut-offs in the LF variables k_\perp^2 and x , i.e., constrain the integration domain by a spherically non-symmetric region, the orientation of which follows the orientation of the LF plane. At first glance, this seems contradictory: (i) the extra form factors $B_{1,3}$, [Eqs. (76c)–(76e)] originate from the spherically non-symmetric cut-offs, but (ii) they do not depend on the cut-off values. This is in fact a normal situation which can be illustrated by the following toy example. Consider the three-dimensional integral

$$I_{ij} = \int^Z \frac{k_i k_j d^3 k}{(k^2 + m^2 + Q^2)^{5/2}} \quad F_{1,ij} \quad (79)$$

It is logarithmically divergent at infinity: $F_1 \sim \int_{k \perp < L} d^3 k / k^2$. Let us introduce the spherically symmetric cut-off $k \perp < L$. A simple calculation gives

$$F_1 = \frac{2}{3} \log \frac{L^2}{m^2 + Q^2} + \frac{4}{9} (\log 8 - 4) + O\left(\frac{1}{L}\right);$$

Let us now regularize this integral by a cut-off imposed on the two-dimensional variable k_\perp in the plane orthogonal to an arbitrary direction n . That is, we set $k_\perp^2 = k^2 - (k \cdot n)^2 < \Lambda^2$. In other words, we integrate over the volume of a cylinder of the radius Λ and of infinite length, with the axis directed along n . The initial

integral turns into

$$I_{ij}^{reg} = \int^Z \frac{k_i k_j}{(k^2 + m^2 + Q^2)^{5/2}} \left[\frac{2}{3} k^2 + (k \cdot n)^2 \right] d^3 k$$

$$F_{1,ij} + B_1(n_i n_j); \quad (80)$$

The integral along n (or over dk_z , if n is parallel to z) converges, similarly to the convergence of the integral over dx in the Feynman amplitude written through the LF variables. We see that the spherically non-symmetric cut-off generates one extra form factor B_1 , like this happens for the Feynman amplitude. We obtain

$$F_1 = \frac{2}{3} \log \frac{\Lambda^2}{m^2 + Q^2} + O\left(\frac{1}{\Lambda}\right);$$

$$B_1 = \frac{2}{3} + O\left(\frac{1}{\Lambda}\right);$$

The leading terms $\sim \log L$ in F_1 and F_1 coincide, provided we identify Λ with L . However, there is a difference in the finite parts: $F_1 - F_1 = \frac{4}{9} (\log 8 - 4)$, like the difference between the term $\frac{15}{16}$ in Eq. (77a) and $\frac{7}{8}$ in Eq. (76a). The transverse cut-off generates a finite extra form factor B_1 , which itself does not depend on Λ , similarly to $B_{1,3}$ in the EM V. This example clearly manifests the properties of the above calculation of the electromagnetic form factors from the Feynman amplitude regularized by the LF cut-offs.

It is therefore misleading to think that one can derive some "true" LF amplitude starting with the covariant Feynman amplitude and calculating it in the LF variables: $I = \int \dots d^4 k = \int \dots d^2 k_\perp dx dk$. This integral diverges (except for some particular cases) and it has no sense without regularization. It depends on the size, shape and orientation of the integration domain constrained by the regularization procedure. In other words, there is no "covariant Feynman amplitude" in itself. There exists only an inseparable couple: the covariant Feynman amplitude together with the rules to regularize it.

When we calculate amplitudes by means of the LFD graph technique rules, the non-invariant integration domain is not the only source of the Λ -dependence. Another source is hidden in the rules themselves. Indeed, these rules are not obliged to reproduce exactly the amplitude which follows from the Feynman approach, even for the same integration domain D . The divergent (and, after regularization, cut-off-dependent) terms are treated non-identically in the two approaches and may be different. This fact is illustrated by the above calculation of the form factor B_3 (cf. Eq. (61e) obtained within LFD with Eq. (76e) coming from the Feynman approach). The renormalization procedures may be different too. However, the renormalized, observed amplitudes must be the same.

When the Λ -dependent contributions to the self-energy and EM V survive, one has to cancel them with appropriate extra counterterms in the interaction Hamiltonian.

These counterterms are inherent to the LFD Hamiltonian and should not be confused with the traditional charge and mass counterterms in the original Lagrangian. The need for such a counterterm for the renormalization of the self-energy was already advocated in Ref. [7], where the non-perturbative fermion mass renormalization was studied in the two-body approximation within covariant LFD. This new counterterm cancels the contribution δ in the self-energy (7).

However, the introduction of additional specific counterterms may help only if their number is finite and tractable. For the case of the fermion self-energy we would need only one ℓ -dependent counterterm, since the coefficient C is a constant. In the case of LFD calculations of the EM V, the form factor B_3 depends non-trivially on the momenta (through Q^2 and ℓ), which would generate an infinite number of local counterterms to kill it, even in perturbation theory. For this reason, the use of counterterms can not serve as an universal tool for the calculation of renormalized quantities in LFD with the traditional transverse and longitudinal cutoffs.

If the renormalization is done correctly, the dependence of any renormalized amplitude on the cutoffs disappears and the final result is the same, regardless to the type of the regularization used. However, from the practical point of view, the difficulty of calculations rapidly increases with introducing extra counterterms. Therefore, rotationally invariant regularization (like the PV one) seems by far more preferable in the LFD framework. The approach developed in Ref. [21], regularizing field theory by defining fields as distributions, could provide another method of rotationally invariant regularization.

V. CONCLUSION

We have calculated perturbatively the fermion self-energy and the EM V in the Yukawa model, in two different ways: (i) by the LFD graph technique rules, taking into account all necessary diagrams; (ii) by integrating the Feynman amplitudes in terms of the LF variables (i.e., the transverse and longitudinal parts of momenta) and summing up the pole, arc, and zero-mode contributions. For the same set of the cutoffs imposed on the LF variables, both methods give different results for the regularized amplitudes. This difference disappears if the invariant PV regularization is used instead of the rotationally non-invariant one.

Such properties follow from the fact that the cutoffs constrain a spherically non-symmetrical integration domain, the symmetry being destroyed by the choice of a distinguished direction defined by the orientation of the LF surface. The dependence of regularized amplitudes on the LF plane orientation is conveniently taken into account in the explicitly covariant version of LFD by constructing extra spin structures. To exclude these structures from the physically observed quantities one may introduce new counterterms in the interaction Hamiltonian,

which also depend on the LF plane orientation. Taking them into account, one can calculate the renormalized amplitudes.

The use of spherically symmetric (in four-dimensional space) regularization, like, for instance, the PV one, considerably simplifies calculations. In perturbation theory it allows to avoid the presence of these extra counterterms at all.

Acknowledgments

Two of us (V.A.K. and A.V.S.) are sincerely grateful for the warm hospitality of the Laboratoire de Physique Corpusculaire, Université Blaise Pascal, in Clermont-Ferrand, where the present study was performed. This work has been partially supported by the RFBR grant No. 05-02-17482-a.

APPENDIX A: KINEMATICAL RELATIONS

We give below some kinematical relations used in the self-energy and EM V calculations within covariant LFD. Amplitudes of the LF diagrams are expressed through the three-dimensional integrals over $d^3k = d^3k$. Take the four-vectors $k = (\ell; k)$ and $p = (p_0; p)$, and construct a new four-vector $R = k - xp$ with $x = (\ell - k) / (\ell - p)$. Since $\ell \cdot R = 0$ and $\ell^2 = 0$, in the reference frame, where $p = 0$, we have $\ell \cdot k = xp_0$ and $k_j = 0$. Taking into account that $\ell^2 = k_0^2 + k^2 + p^2$ and changing p_0 to ℓ^2 / p^2 , we arrive at the relations

$$k_j = \frac{k_0^2 + p^2}{2x} \frac{x^2 p^2}{p^2}; \quad \ell^2 = \frac{k_0^2 + p^2 + x^2 p^2}{2x} \frac{p^2}{p^2}.$$

In the variables k_0 and x , the invariant phase space element becomes

$$d^3k = d^3k = d^2k_0 dx = x. \quad (A1)$$

We can now express the scalar product $k \cdot p$ entering the quantity (4), through k_0^2 and x . For this purpose, we represent the invariant quantity R^2 in two different ways:

$$R^2 = (k - xp)^2 = \ell^2 - 2x(k \cdot p) + x^2 p^2$$

and

$$R^2 = (\ell - xp)^2 = k_0^2 - k^2 = k_0^2.$$

Equating the right-hand sides of these expressions yields

$$k \cdot p = \frac{k_0^2 + p^2 + x^2 p^2}{2x}. \quad (A2)$$

In the calculation of the EM V we have one more four-vector p^0 . We define two new four-vectors $R = k - xp$ and

$R^0 = k^0 x^0 p^0$, where $x^0 = (1 - k^0) / p^0$, $x = (1 + k^0) / p^0$. From the equalities $k^0 R^0 = k^0 R^0$, in the reference frame, where $p^0 = 0$, follows $R^2 = R_0^2 = k_0^2$, $R^{02} = R_0^{02} = (k_0^0 x^0)^2$, where $k_0^0 = p_0^0 = q_0^0$. Analogously to Eq. (A 2), we get from here

$$k^0 p^0 = \frac{k_0^2 + x^2 + x^2 m^2}{2x}; \tag{A 3a}$$

$$k^0 p^0 = \frac{(k_0^0 x^0)^2 + x^2 + x^2 m^2}{2x^0}; \tag{A 3b}$$

From these formulas follow the expressions (45a) and (45b). For completeness, we give here the other scalar products which are needed for the EMV calculations:

$$\begin{aligned} k^0 p^0 &= x^0 (1 - p^0); \\ k^0 p^0 &= (1 + x^0) (1 - p^0); \\ p^0 p^0 &= \frac{Q^2}{2} + m^2; \\ k^2 &= 0; \quad p^2 = p^{02} = m^2; \quad k^2 = x^2; \end{aligned}$$

After integrating over the azimuthal angle of the vector k^0 , the form factors depend on x^2 , and one should relate it with the invariant square of the momentum transfer $Q^2 = (p^0 - p^0)^2$. If one had $k^0 p^0 = k^0 p^0$ (equivalent to $k^0 p^0 = 0$), it would be simply $Q^2 = x^2$. In our case the relation is more complicated. Indeed, since $k^0 p^0 = k^0 p^0$, we have, on the one hand, $k^0 p^0 = (1 + x^0) k^0 p^0$, and, on the other hand, $k^0 p^0 = k^0 p^0 (x^2 + p_k^{02} + m^2 - p_k^{02})$. We thus find

$$k^0 p^0 = \frac{x^2 m^2 (2 + x^0)}{2m (1 + x^0)}$$

and

$$Q^2 = (x^2 + p_k^{02} + m^2 - m^2) - p_k^{02} = \frac{x^2 + x^2 m^2}{1 + x^0}; \tag{A 4}$$

From here Eq. (46) follows.

APPENDIX B: DERIVING THE LIGHT-FRONT SELF-ENERGY FROM THE FEYNMAN APPROACH

Proceeding from the Feynman amplitude (19) for the self-energy, Sec. IIB, we calculate here the pole, arc, and zero-m mode contributions.

1. Pole and arc contributions

We first consider the integral over dk^0 in Eq. (20) for the x -integration in the limits $1 - x < x < 1$, and $1 + x < x < +1$, determining $p_{+a}(p)$. It can be calculated directly (by primitive). However, in order

to get the results in a form closer to LFD, we will use the residues. The integrand has two poles in the points

$$k^0 = k^{(1)} = \frac{k_+^2 + x^2 - i0}{xp_+}$$

and

$$k^0 = k^{(2)} = p_+ \frac{k_+^2 + m^2 - i0}{(1 - x)p_+}$$

If $1 - x < x < 1$ or $1 + x < x < +1$, both poles lay, respectively, above or below the real axis. If $x < 1$ the poles are situated on the opposite sides from the real axis. We close the integration contour by an arc of a circle of the radius L , either in the upper half-plane or in the lower one, so that the pole $k^{(2)}$ is always outside the contour. The situation is illustrated in Fig. 6, where the integration contour is shown for the case $x < 1$.

Note that the order of integrations we have chosen in Eq. (20) requires some care in treating the cuts. Since the integration over dk^0 is performed first, we should keep L arbitrary large, while the other cuts and p_+ are considered as being finite. In other words, we imply that $L \gg p_+ = (m^2)$. Such a convention ensures mutual position of the poles and the contour, as exposed above. Then $p_{+a}(p)$ is represented as

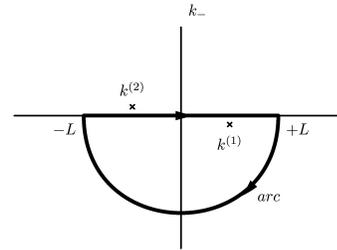

FIG. 6: Contour of the integration over dk^0 . Positions of the poles are shown for $x < 1$.

$$p_{+a}(p) = \frac{ig^2 p_+}{32 \pi^4} \int_{-L}^{+L} dk^0 \int_{1-x}^{1+x} dx \left[\text{pole}_{\text{arc;low}} + \text{pole}_{\text{arc;up}} \right]; \tag{B 1}$$

where $\text{pole}_{\text{arc;low}}$ is the residue at the pole $k^{(1)}$, multiplied by $2\pi i$, while arc_{low} and arc_{up} come from the integrations along the arcs in the lower and upper half-planes, respectively. The result for $\text{pole}_{\text{arc;low}}$ reads

$$\text{pole}_{\text{arc;low}} = \frac{2\pi i (p_+ k_+ + m^2)}{p_+ [k_+^2 + m^2 x - p_+^2 x (1 - x) + x^2 (1 - x)]}; \tag{B 2}$$

The four-vector k here is an on-mass-shell four-vector ($k^2 = x^2$) with the components expressed through k_+

and x as follows: $k = (k_\perp; k_+; k_\perp) = (\frac{k_\perp^2 + m^2}{xp_+}; xp_+; k_\perp)$. To calculate arc_{low} and arc_{up} , we should move along the arc in the clockwise and counter-clockwise directions, respectively. In the points of the arc $k = Le^i$ and $dk = iLe^i d$, where θ is an azimuthal angle. In the limit $L \rightarrow 1$, we retain in the integrand the dominating k_\perp -term. We thus obtain

$$\text{arc}_{\text{low}} = \text{arc}_{\text{up}} = \frac{i}{2p_+^2 x(1-x)}; \quad (\text{B } 3)$$

Substituting Eqs. (B 2) and (B 3) into Eq. (B 1) and going over to the explicitly covariant notations by means of the identities $p_+ = \theta$, $p_\perp = \sqrt{1 - \theta}$, we obtain that $\text{p}_{\text{a}}(\text{p})$ is given by Eq. (23).

2. Zero modes

Consider now the zero-mode term $\text{z}_m(\text{p})$. We denote

$$\text{z}_m(\text{p}) = \text{z}_m^{(0)}(\text{p}) + \text{z}_m^{(1)}(\text{p});$$

where the two items on the right-hand side correspond to the contributions to Eq. (20) from the infinitesimal integration regions $0 < x < 1$ and $1 < x < 1 + \epsilon$, respectively. Take first $\text{z}_m^{(0)}(\text{p})$ (bosonic zero modes). If $x = 0$, the term $k_\perp p_+ x$ in the denominator of the integrand disappears and the integral over dk_\perp diverges linearly. This infinite contribution should therefore be proportional to $\ln(x)$. We take $x \rightarrow 0$ and keep in the numerator and in the denominator of the integrand in Eq. (20) the leading k_\perp -terms (where k_\perp is not multiplied by x) only. That is

$$\text{z}_m^{(0)} = \frac{ig^2 p_+}{32^4} \int_0^L \int_0^L dx d^2 k_\perp \frac{1}{[k_\perp p_+ x + k_\perp^2 + m^2 + i0] (k_\perp p_+)}; \quad (\text{B } 4)$$

The double integral over $dx dk_\perp$ is of the type of Eq. (E 1) with $b = (k_\perp^2 + m^2)p_+$ and $h = 0$ (see Appendix E). Using Eq. (E 2), we obtain, in the covariant notations:

$$\text{z}_m^{(0)}(\text{p}) = \frac{g^2 \theta}{32^3 (\theta - p)} \int d^2 k_\perp \log \frac{(\theta - p)L}{k_\perp^2 + m^2} \log \frac{1}{k_\perp^2 + m^2}; \quad (\text{B } 5)$$

Changing the variable $x \rightarrow 1 - x$, for $\text{z}_m^{(1)}(\text{p})$ (fermionic zero modes) we similarly get

$$\text{z}_m^{(1)}(\text{p}) = \frac{g^2 \theta}{32^3 (\theta - p)} \int d^2 k_\perp \log \frac{(\theta - p)L}{k_\perp^2 + m^2} \log \frac{1}{k_\perp^2 + m^2}; \quad (\text{B } 6)$$

Taking the sum of (B 5) and (B 6), we find that it has the form of eq. (26): $\text{z}_m(\text{p}) = g^2 C_{zm} \frac{m^2}{p}$ with

$$C_{zm} = \frac{g^2}{32^2} \int_0^2 dk_\perp^2 \log \frac{k_\perp^2 + m^2}{k_\perp^2 + m^2}$$

Calculating this integral, we find Eq. (27) for C_{zm} .

APPENDIX C: LIGHT-FRONT CONTRIBUTIONS TO THE FORM FACTORS

In this Appendix, starting with the LF vertices (A) , (B) , and (C) found in Sec. III A 2, Eqs. (52a)–(52c), we calculate their contributions to form factors $F_{1;2}, B_{1;3}$.

1. Preliminary transformations

Each contribution to a form factor F ($F = F_i$ or B_i) from the vertices (A) , (B) , or (C) can be written as an integral of the form

$$F = \int_{x_{m \text{ in}}}^{x_{m \text{ ax}}} dx \int_0^2 dk_\perp^2 \int_0^2 d\theta f(k_\perp^2; x; Q^2); \quad (\text{C } 1)$$

where θ is the angle between the two-dimensional vectors k_\perp and p_\perp , f is a given function (f 's are different for different form factors), and the modulus of p_\perp is expressed through Q^2 by Eq. (46). The limits $x_{m \text{ in}}$ and $x_{m \text{ ax}}$ depend on which vertex is considered.

The analysis of the dependence of the form factors on the cutoff θ (when it tends to infinity) allows to represent each of them as

$$F = a_1 \theta^2 + a_2 \log \frac{\theta}{m} + a_{\text{reg}}; \quad (\text{C } 2)$$

where the coefficients a_1 , a_2 , and a_{reg} are regular functions depending on the particle masses, Q^2 , and m , but independent of θ . If $\theta \neq 0$, no other divergencies (i.e., cutoff-dependent terms) excepting those listed in Eq. (C 2) appear. Since the coefficients a_1 and a_2 determine the dependence of the form factors on the cutoff θ , we will calculate them at arbitrary θ , in order to see in detail how the cutoff disappears (if so!) after taking into account all the contributions (A) , (B) , and (C) to the full EM V and its subsequent renormalization. As far as the coefficients a_{reg} are concerned, we will find them in the limit $\theta \rightarrow 0$, retaining non-vanishing terms only. This simplifies calculations a lot, but leads to the same final result as if θ was non-zero.

Although direct integrations over d and dk_\perp^2 can always be done analytically for arbitrary Q^2 and m , the results turn out to be very cumbersome, so that the final integration over dx (if it can be done analytically) takes too much time. To make the computations more effective, we will proceed in the following way. We take the

initial expression for a given form factor in the form of Eq. (C 1) and study the behavior of the integrand as a function of $k_?^2$ in the asymptotic region $jk_? j! 1$. For this purpose we decompose it in a Laurent series:

$$f(k_?^2; \mathbf{x}; Q^2;) = f_0(\mathbf{x}; Q^2;) + \frac{f_1(\mathbf{x}; Q^2;) \cos}{jk_? j} + \frac{f_2(\mathbf{x}; ; Q^2;)}{k_?^2} + \dots \quad (\text{C } 3)$$

We use this decomposition in order to define the functions f_0 and f_2 (the term with f_1 drops out after the integration over d). We then represent f as a sum

$$f(k_?^2; \mathbf{x}; Q^2;) = f_{\text{reg}}(k_?^2; \mathbf{x}; Q^2;) + f_0(\mathbf{x}; Q^2;) + \frac{f_2(\mathbf{x}; Q^2;)}{k_?^2 + m^2(\mathbf{x})}; \quad (\text{C } 4)$$

where

$$f_2(\mathbf{x}; Q^2;) = \frac{1}{2} \int_0^{Z_2} f_2(\mathbf{x}; ; Q^2;) d \quad (\text{C } 5)$$

and (\mathbf{x}) is a positive function which can be chosen in any convenient way in order to avoid the singularity at $k_?^2 = 0$. Eq. (C 4) should be considered as a definition of the function $f_{\text{reg}}(k_?^2; \mathbf{x}; Q^2;)$. The latter, after the integration over d , decreases faster than $1/k_?^2$ in the asymptotic region, and its integration over $dk_?^2$ does not require any regularization. The functions $f_0(\mathbf{x}; Q^2;)$ and $f_2(\mathbf{x}; Q^2;)$ are rather simple, so that the two last addenda on the right-hand side of Eq. (C 4) can be easily integrated over all the variables.

After separating out the terms which slowly decrease when $jk_? j! 1$, we remain with a set of regular functions f_{reg} . At arbitrary Q^2 , these functions are even more complicated than the initial integrands f . However, we calculate the regular contributions to the form factors in the limit $Q^2 \rightarrow \infty$. So, it is enough to consider the limiting functions $f_{\text{reg}}(k_?^2; \mathbf{x}; Q^2; \rightarrow \infty)$ which are much simpler than $f(k_?^2; \mathbf{x}; Q^2;)$. If f_{reg} is singular at $k_?^2 = 0$, we decompose it in powers of $k_?^2$ and retain all non-vanishing terms.

The trick exposed above allows to find the coefficients in Eq. (C 2). Indeed, substituting Eq. (C 4) into Eq. (C 1), we get

$$a_1 = 2 \int_{x_{m \text{ ax}}}^{x_{m \text{ in}}} f_0(\mathbf{x}; Q^2;) dx; \quad (\text{C } 6a)$$

$$a_2 = 4 \int_{x_{m \text{ ax}}}^{x_{m \text{ in}}} f_2(\mathbf{x}; Q^2;) dx; \quad (\text{C } 6b)$$

$$a_{\text{reg}} = \int_{x_{m \text{ in}}}^{x_{m \text{ ax}}} dx \int_0^{Z_1} dk_?^2 d f_{\text{reg}}(k_?^2; \mathbf{x}; ; Q^2; \rightarrow \infty) + 2 \int_{x_{m \text{ ax}}}^{x_{m \text{ in}}} f_2(\mathbf{x}; Q^2; \rightarrow \infty) \log(\mathbf{x}) ; \quad (\text{C } 6c)$$

The integrations over d and $dk_?^2$ can be done analytically for all the vertex form factors. For $F_{1,2}$ the results of the remaining integrations over dx at arbitrary Q^2 and are not expressed through elementary functions. In order to simplify the formulas, we decompose both $F_{1,2}$ in powers of Q^2 up to terms of order Q^2 and take the limit $Q^2 \rightarrow \infty$. Concerning the form factors $B_{1,3}$, all the integrations are performed analytically without any approximation.

Below, in Secs. C 2{C 4, we list the coefficients $a_1, a_2,$ and a_{reg} entering Eq. (C 2), pointing out in superscripts which form factor the given coefficient belongs to. The coefficients are calculated by means of Eqs. (C 6), separately for the vertices $(A), (B),$ and (C) [see Eqs. (54) and (55)].

2. Contribution to the form factors from (A)

It is convenient to set in Eq. (C 4) $(\mathbf{x}) = x^2 + \frac{2}{m^2}(1-x)$. The limits of the x -integration are $x_{m \text{ in}} = 0, x_{m \text{ ax}} = 1$. Then

$$a_1^{F_1} = a_1^{F_2} = a_1^{B_1} = a_1^{B_2} = a_1^{B_3} = 0; \quad (\text{C } 7)$$

$$\begin{aligned} a_2^{F_1} &= \frac{g^2 2(1+Q^2) + 2(2-m^2)m^2}{16^2(1+Q^2)^2 z}; \quad a_2^{F_2} = 0; \\ a_2^{B_1} &= \frac{g^2(2+Q^2)(1+Q^2) + 2m^2}{16^2(1+Q^2)^2 z}; \\ a_2^{B_2} &= \frac{g^2}{16^2(1+Q^2)} \frac{4^2(2+2+Q^2)m^2 + [8+(2+Q^2)(8+2+Q^2)]Q^2}{(1+Q^2)(2+Q^2)z} 4; \\ a_2^{B_3} &= \frac{g^2}{16^2 m^2 (1+Q^2)^2} (2+Q^2)^2 \frac{(3+3+Q^2)m^2}{1+Q^2} \frac{Q^2[(1+Q^2)Q^2 + 2m^2]}{z}; \end{aligned} \quad (\text{C } 8)$$

where $z = (2 + 2 + \dots)^2 Q^2 + 2^2 m^2$, and

$$\begin{aligned} a_{\text{reg}}^{F_1} &= \frac{g^2}{4^2} \log \frac{m}{8} - \frac{7}{24^2 m^2} \frac{g^2 Q^2}{\log \frac{m}{8}} + O(Q^4); \\ a_{\text{reg}}^{F_2} &= \frac{3g^2}{16^2} - \frac{g^2 Q^2}{32^2 m^2} + O(Q^4); \\ a_{\text{reg}}^{B_1} &= \frac{g^2}{64^2} (1 + 4'(Q^2)); \\ a_{\text{reg}}^{B_2} &= \frac{g^2}{32^2} (1 + 4'(Q^2)); \\ a_{\text{reg}}^{B_3} &= \frac{g^2}{32^2 m^2} (2 + 2 \log \frac{m}{8} + 1 - (4m^2 - 2^2 + Q^2)'(Q^2)); \end{aligned} \quad (\text{C } 9)$$

with

$$'(Q^2) = 1 - \frac{s}{1 + \frac{4m^2}{Q^2}} \log \frac{p}{Q^2 + 4m^2 + p} \frac{p}{Q^2} : \quad (\text{C } 10)$$

3. Contribution to the form factors from ^(B)

We set $(x) = 1$, $x_{\text{min}} = 1$, $x_{\text{max}} = 1 + \dots$. We thus get

$$\begin{aligned} a_1^{F_1} &= a_1^{F_2} = a_1^{B_1} = a_1^{B_2} = 0; \\ a_1^{B_3} &= \frac{g^2}{32^2 m^2} \frac{\log(1 + \dots)}{(1 + \dots)}; \\ a_2^{F_1} &= \frac{g^2}{16^2} (1 - \frac{2(1 + \dots)Q^2 + \dots(2^2 m^2)}{(1 + \dots)^2 z}); \quad a_2^{F_2} = 0; \\ a_2^{B_1} &= \frac{g^2 (2 + \dots)(1 + \dots)Q^2 + \dots m^2}{16^2 (1 + \dots)^2 z}; \\ a_2^{B_2} &= \frac{g^2}{16^2 (1 + \dots)} \frac{4^2 (2 + 2 + \dots)m^2 + \dots (2 + \dots)(8 + 2 + \dots)Q^2}{(1 + \dots)(2 + \dots)z} - 4; \\ a_2^{B_3} &= \frac{g^2}{16^2 m^2 (1 + \dots)^2} (2 + \dots) \frac{m^2}{1 + \dots} - \frac{Q^2 [(1 + \dots)Q^2 - \dots m^2]}{z} : \end{aligned} \quad (\text{C } 11)$$

While integrating over dx in Eq. (C 6c), we introduce a new variable $z = (x - 1) = \dots$. Then

$$\int_{1-}^{z_1+} dx (\dots) = \int_{z_1}^{z_1+} d(\dots) :$$

After that the integrands f_{reg} should be decomposed in powers of z up to terms of order $l = \dots$. Performing this transformation, we obtain the following result:

$$\begin{aligned} a_{\text{reg}}^{F_1} &= a_{\text{reg}}^{F_2} = 0; \\ a_{\text{reg}}^{B_1} &= \frac{1}{2} a_{\text{reg}}^{B_2} = \frac{g^2}{16^2} '(Q^2); \\ a_{\text{reg}}^{B_3} &= \frac{g^2}{32^2 m^2} \frac{Q^2}{z} + (4m^2 - 2^2 + Q^2)'(Q^2) \end{aligned} \quad (\text{C } 12)$$

with $'(Q^2)$ given by Eq. (C 10).

4. Contribution to the form factors from ^(C)

The matrix structure of the vertex ^(C) is the same as the one in front of the form factor B_3 in the decomposition (56). For this reason ^(C) contributes to B_3 only. From Eq. (60) we easily find

$$a_1^{B_3} = \frac{g^2}{32^2 m^2} \frac{\log(1 + \dots)}{(1 + \dots)}; \quad (\text{C } 13)$$

all the other coefficients being zero.

APPENDIX D : DERIVING THE LIGHT-FRONT ELECTROMAGNETIC VERTEX FROM THE FEYNMAN APPROACH

Proceeding from the Feynman amplitude (69) for the EM V, Sec. IIIB, we calculate here the pole, arc, and zero-mode contributions.

1. Preliminary transformations

Under the condition $p_+^0 = p_+ = 0$, the LF components of the four-vectors p and p^0 are

$$\begin{aligned} p_-^0 &= 0; \quad p_- = \frac{m^2}{p_+}; \\ p_+^0 &= q_-^0; \quad p_+^0 = \frac{p_+^2 + m^2}{p_+}; \end{aligned} \quad (D1)$$

where q_-^0 is the transversal part of the three-dimensional momentum transfer:

$$q_-^0 = p_-^0 - p_-; \quad Q^2 = (p_-^0 - p_-)^2 = q_-^0{}^2;$$

Introducing a new variable x by means of the relation $k_+ = xp_+$ and using the notations

$$a = \frac{k_-^2 + m^2}{p_+}; \quad b = \frac{k_-^2 + m^2}{p_+}; \quad b^0 = \frac{(k_-^0 - q_-^0)^2 + m^2}{p_+}; \quad (D2)$$

we cast Eq. (70) in the form

$$= \frac{ig^2}{128^4 p_+^2} \int_{-1}^1 dx \int_{-1}^1 d^2k_- \frac{1}{v_1 v_2 v_2^0}; \quad (D3)$$

where

$$\begin{aligned} v_1 &= xk_+ - a + i0; \\ v_2 &= (x-1)k_+ - b + (x-1)p_+ + i0; \\ v_2^0 &= (x-1)k_+ - b^0 + (x-1)p_+^0 + i0; \end{aligned} \quad (D4)$$

$$\begin{aligned} M &= (x-1)p_+ - p_+ + 2k_-^0 - 2m; \\ M^0 &= (x-1)p_+ - p_+^0 + 2(k_-^0 - q_-^0) - 2m; \end{aligned} \quad (D5)$$

The matrices M and M^0 do not depend on k_- .

The integral in Eq. (D3) diverges at $|k_-^j| \rightarrow \infty$. If $x = 0$ or $x = 1$, it diverges also at $k_+ \rightarrow \infty$. We constrain the integration over dk_-^2 in $d^2k_- = \frac{1}{2} dk_-^2 d\phi$ by the cutoff Λ^2 , and introduce also the cutoff sL in k_+ , as in Eq. (21), and in x , splitting the region of the integration over dx into three "normal" regions $-1 < x < -1 + \epsilon$, $-1 + \epsilon < x < 1 - \epsilon$, and $1 - \epsilon < x < 1$ and two infinitesimal ones $-1 - \epsilon < x < -1$, $1 < x < 1 + \epsilon$. The integrals over the "normal" regions are calculated by summing up the residue and arc contributions, as in Sec. IIIB 1. The contributions (if any) from the two infinitesimal regions of the integration over dx , which do not vanish in the limit $\epsilon \rightarrow 0$, correspond to the zero modes. Because of rather weak (logarithmic) divergence of the initial integral (69) we expect that the result of the full integration over dk_- and dx has a finite limit at $L \rightarrow \infty$ and $s \rightarrow \infty$, while the remaining integration over d^2k_- produces logarithmic dependence of the EM V on the cutoff Λ^2 .

2. Pole and arc contributions

We start with the calculation of $\Gamma^{(p+a)}$. The procedure is quite similar to that exposed in Appendix B 1 and in the papers [9, 10, 15, 16, 17]. The integrand in Eq. (D3) has three poles:

$$\begin{aligned} k^{(1)} &= \frac{a - i0}{x}; \\ k^{(2)} &= \frac{b + (x-1)p - i0}{x-1}; \\ k^{(3)} &= \frac{b^0 + (x-1)p^0 - i0}{x-1}; \end{aligned} \quad (D6)$$

If $-1 < x < -1 + \epsilon$ or $1 + \epsilon < x < 1$, all of them are, respectively, either in the upper halfplane of k_+ or in the lower one. If $-1 + \epsilon < x < 1 - \epsilon$, the pole $k^{(1)}$ is in the lower halfplane, while the poles $k^{(2)}$ and $k^{(3)}$ are in the upper one. We can thus write, analogously to Eq. (B1):

$$\Gamma^{(p+a)} = \frac{ig^2}{128^4 p_+^2} \int_{-1}^1 dx \int_{-1}^1 d^2k_- \left[\text{pole} + \text{arc}_{\text{low}} + \text{arc}_{\text{up}} \right]; \quad (D7)$$

where pole equals the residue of the integrand in the pole $k_+ = k^{(1)}$, multiplied by $2\pi i$:

$$\text{pole} = \frac{8 ip_+^2}{x} \frac{(p_-^0 - k_-^0 - m)(p_-^0 - k_-^0 + m)}{[(p_-^0 - k_-^0)^2 - m^2][(p_-^0 - k_-^0)^2 - m^2]} \quad (D8)$$

with $k_-^2 = \Lambda^2$, and the arc contributions are

$$\text{arc}_{\text{low}} = \text{arc}_{\text{up}} = \frac{i}{x(1-x)^2} + \dots; \quad (D9)$$

Substituting Eqs. (D8) and (D9) into Eq. (D7), we find

$$G^{(p+a)} = \frac{g^2}{16^3} \int_0^1 dx \frac{(\epsilon^0 \epsilon + m) (\epsilon \epsilon + m)}{[(\epsilon^0 k)^2 + m^2][(\epsilon k)^2 + m^2]} + \frac{1}{4p_+^2} \log \frac{1}{\dots} \quad (D 10)$$

We substitute here $\log(1-x)$ by $\int_0^1 dx = x$ and take the limit $\epsilon \rightarrow 0$. The latter is achieved simply by setting $\epsilon = 0$ in the integration limits, because the integrand is no more singular neither at $x = 0$ nor at $x = 1$. We also return to the covariant notations, replacing ϵ by ϵ and p_+ by p . In this way we find that $G^{(p+a)}$ is given by Eq. (72).

3. Zero modes

Let us now consider the zero mode contribution to Eq. (D 3). It can be written as

$$G^{(zm)} = \frac{ig^2}{128^4 p_+^2} \int_0^1 dx \int_{-L}^L dk G^{(x=0)} + G^{(x=1)}; \quad (D 11)$$

where

$$G^{(x=0)} = \int_{-L}^L dx \int_{-L}^L dk \frac{[k_+ + M^0] [k_+ + M]}{v_1 v_2 v_2^0}; \quad (D 12a)$$

$$G^{(x=1)} = \int_0^1 dx \int_{-L}^L dk \frac{[k_+ + M^0] [k_+ + M]}{v_1 v_2 v_2^0}; \quad (D 12b)$$

In order to calculate these integrals, we need their asymptotical limit when $L \rightarrow \infty$ and $\epsilon \rightarrow 0$. As explained in Sec. II B 1, one should take the limit $L \rightarrow \infty$ first, while keeping ϵ finite, and then allow $\epsilon \rightarrow 0$.

We represent $G^{(x=0)}$ as

$$G^{(x=0)} = \int_{-L}^L dx \int_{-L}^L dk \frac{k^2}{v_1 v_2 v_2^0} + (M^0 + \dots + M) \frac{k}{v_1 v_2 v_2^0} + M^0 M \frac{1}{v_1 v_2 v_2^0};$$

For further calculations, we will make use of the formulas

$$\frac{k^n}{v_1 v_2 v_2^0} = \frac{D_n(x)}{v_1} + \frac{E_n(x)}{v_2} + \frac{F_n(x)}{v_2^0}; \quad n = 0; 1; 2; \quad (D 13)$$

where v_1 , v_2 , and v_2^0 are defined by Eqs. (D 4), and the functions $D_n(x)$, $E_n(x)$, and $F_n(x)$ are

$$\begin{aligned} D_0(x) &= \frac{x^2}{t_1 t_1^0}; & E_0(x) &= \frac{x-1}{t_1 t_2}; & F_0(x) &= \frac{x-1}{t_1^0 t_2}; \\ D_1(x) &= \frac{ax}{t_1 t_1^0}; & E_1(x) &= \frac{b+(x-1)p}{t_1 t_2}; & F_1(x) &= \frac{b^0+(x-1)p^0}{t_1^0 t_2}; \\ D_2(x) &= \frac{a^2}{t_1 t_1^0}; & E_2(x) &= \frac{[b+(x-1)p]^2}{(x-1)t_1 t_2}; & F_2(x) &= \frac{[b^0+(x-1)p^0]^2}{(x-1)t_1^0 t_2}; \end{aligned} \quad (D 14)$$

with

$$\begin{aligned} t_1 &= (x-1)(xp-a) + bx; \\ t_1^0 &= (x-1)(xp^0-a) + b^0x; \\ t_2 &= b-b^0 + (p-p^0)(x-1); \end{aligned}$$

The values of a , b , and b^0 are defined by Eqs. (D 2).

After the transformation (D 13), the problem of finding $G^{(x=0)}$ reduces to the calculation of integrals of the

following three types:

$$\begin{aligned} \int_{-L}^L dx f(x) \int_{-L}^L \frac{dk}{v_1}; \\ \int_{-L}^L dx f(x) \int_{-L}^L \frac{dk}{v_2}; \\ \int_{-L}^L dx f(x) \int_{-L}^L \frac{dk}{v_2^0}; \end{aligned} \quad (D 15)$$

with various functions $f(x)$, being either $D_n(x)$, $E_n(x)$, and $F_n(x)$, or their products with M and M^0 . It is easy to see that the latter two integrals in Eqs. (D 15) always

give zero in the limit $\epsilon \rightarrow 0$, while the first one is of the type of the integral (E 4) from Appendix E. Using the formula (E 4) and taking into account that $D_2(0) = 1$, we get

$$\begin{aligned} G^{(\kappa=0)} &= \int_0^Z dx D_2(x) \int_0^L \frac{dk}{v_1} \\ &= \int_0^Z dx \left[2 + 2i \log \frac{L}{a} \log \frac{1}{\epsilon} \right] : \end{aligned} \quad (D 16)$$

The calculation of $G^{(\kappa=1)}$ is similar, but the algebra is more lengthy. Changing the variable $x \rightarrow x-1$, we have

$$\begin{aligned} G^{(\kappa=1)} &= \int_0^Z dx \int_0^L \frac{dk}{u_1 u_2 u_2^0} + \int_0^L \frac{k^2}{u_1 u_2 u_2^0} \\ &+ (M_{10}^0 + M_{10}) \frac{k}{u_1 u_2 u_2^0} \\ &+ M_{10}^0 M_{10} \frac{1}{u_1 u_2 u_2^0} ; \end{aligned}$$

where

$$\begin{aligned} u_1 &= (x+1)k - a + i0; \\ u_2 &= xk - b - xp + i0; \\ u_2^0 &= xk - b^0 - xp^0 + i0; \end{aligned} \quad (D 17)$$

$$\begin{aligned} M_{10} &= xp_+ - p_+ - 2k_? - 2m; \\ M_{10}^0 &= xp_+ - p_+^0 - 2(k_? - q_?) - 2m; \end{aligned} \quad (D 18)$$

We have now, instead of Eq. (D 13):

$$\begin{aligned} \frac{k^n}{u_1 u_2 u_2^0} &= \frac{D_n(x+1)}{u_1} + \frac{E_n(x+1)}{u_2} + \frac{F_n(x+1)}{u_2^0}; \\ n &= 0; 1; 2; \end{aligned} \quad (D 19)$$

Again, we encounter integrals of the types (D 15), v 's being changed by u 's. The terms with u_2 and u_2^0 in the denominators contribute only, while those with u_1 disappear in the limit $\epsilon \rightarrow 0$, after the integration over dx . Using the formulas (E 4) and (E 5) from Appendix E, we obtain after some transformations:

$$\begin{aligned} G^{(\kappa=1)} &= \int_0^Z dx \left[2 + 2i \log \frac{L}{a} \log \frac{1}{\epsilon} \right] \\ &+ 2i H_1(k_?)g \\ &+ 2ip_+ [M_{10}^0 + M_{10}] H_2(k_?); \end{aligned} \quad (D 20)$$

where

$$\begin{aligned} M_{10} &= p_+ - 2k_? - 2m; \\ M_{10}^0 &= p_+^0 - 2(k_? - q_?) - 2m; \\ H_1(k_?) &= \frac{p_+ - p_+^0}{b - b^0} + \log \frac{a}{b} \\ &+ \frac{(a - b^0)(b - b^0) + bp_+ - b^0 p_+}{(b - b^0)^2} \log \frac{b}{b^0}; \\ H_2(k_?) &= \frac{1}{p_+ (b - b^0)} \log \frac{b}{b^0}; \end{aligned}$$

In order to find the form factors $F^{(z_m)}$ from the vertex (z_m) , it is convenient to cast the latter in an explicitly covariant form. For this purpose we introduce the four-vectors

$$\begin{aligned} r &= (r; r_+; r_?) = (p; 0; k_?); \\ r^0 &= (r^0; r_+^0; r_?^0) = (p^0; 0; q_? - k_?); \end{aligned}$$

Then, taking the sum of Eqs. (D 16) and (D 20), substituting it into Eq. (D 11), and changing everywhere $\epsilon \rightarrow \epsilon$, $p_+ \rightarrow p_+$, we arrive at the desired result:

$$\begin{aligned} F^{(z_m)} &= \frac{g^2}{32\pi^3} \int d^2 k_? \frac{\epsilon!}{(\epsilon - p)!} H_1(k_?) \\ (\epsilon^0 + m) &= \frac{\epsilon}{\epsilon!} + \frac{\epsilon}{p!} (\epsilon + m) H_2(k_?) : \end{aligned} \quad (D 21)$$

To find the form factors, one should substitute (z_m) into Eq. (57), instead of (z) , then find c_{15} by means of Eqs. (58), and finally revert the system of linear equations (59) taken for $\epsilon = 0$. We give here the result:

$$\begin{aligned} F_1^{(z_m)} &= F_2^{(z_m)} = 0; \\ B_i^{(z_m)} &= \frac{g^2}{32\pi^3} \int d^2 k_? b_i(k_?); \end{aligned}$$

where

$$\begin{aligned} b_1(k_?) &= H_2(k_?); \quad b_2(k_?) = 2H_2(k_?); \\ b_3(k_?) &= \frac{1}{m^2} H_1(k_?) - 2(k_? - q_+ + m^2) H_2(k_?) : \end{aligned}$$

It is convenient to use the following representations:

$$\begin{aligned} H_1(k_?) &= \int_0^1 dz \frac{zp_+ + (1-z)p_+^0 + a - b^0}{bz + b^0(1-z)} \\ &+ \frac{a - b}{az + b(1-z)}; \\ H_2(k_?) &= \frac{1}{p_+} \int_0^1 dz \frac{1}{bz + b^0(1-z)}; \end{aligned}$$

which can be checked by direct integration. Calculating first the integrals over $d^2 k_?$ and then over dz , we find the zero mode contribution to the form factors, Eqs. (75).

APPENDIX E: CALCULATION OF THE ZERO-MODE INTEGRALS

Finding the zero mode contribution to the self-energy and EMV requires calculation of the asymptotic value of the integral

$$I_1 = \int_0^Z dx \int_0^L \frac{dk}{xk - b - xp + i0} \quad (E 1)$$

at $L \rightarrow 1$ and $\epsilon \rightarrow 0$ (b and h are considered as finite quantities independent both of k and x). As we shall see below, the real part of I_1 is finite in this limit, so that

$$\begin{aligned} \text{Re} I_1 &= \text{Re} \int_{-L}^L dx \int_{-L}^L dk \frac{1}{xk - b - ih + i0} \\ &= \text{Im} \lim_{\epsilon \rightarrow 0} \int_{-L}^L dx \int_{-L}^L dk \frac{1}{dy e^{i(xk - b - ih + i0)y}} \\ &= 2 \text{Im} \lim_{\epsilon \rightarrow 0} \int_{-L}^L dy e^{i(b - ih)y} \int_{-L}^L dx e^{-ihxy} \text{sgn}(xy) \\ &= 2 \int_{-L}^L dy \frac{\sin by}{y} \\ &= 2 \text{sgn}(b): \end{aligned}$$

The imaginary part of I_1 is divergent in L and ϵ , and we have to retain finite values of the cut-offs:

$$\text{Im} I_1 = \int_{-L}^L dx \int_{-L}^L dk (xk - b - ih):$$

Using the identity $\text{sgn}(z) = -i(\epsilon - z)/(\epsilon + iz)$, we can easily see that $\text{Im} I_1$ does not change under the transformation $b \rightarrow -b$. It is thus legitimate to substitute b by $|b|$. Calculating the integral by means of the ζ -function, we get

$$\begin{aligned} \text{Im} I_1 &= \int_{-L}^L \frac{|b|}{L+h} dx + \int_{-L}^L \frac{dx}{L-h} \\ &= \log \frac{L^2 - h^2}{b^2} + 2 \log \frac{L}{|b|}: \end{aligned}$$

Collecting the results together and neglecting the terms of order $(L-h)^2$ and higher, we finally obtain

$$I_1 = 2 \text{sgn}(b) - 2i \log \frac{L}{|b|} - \log \frac{1}{|b|}: \quad (E 2)$$

Let us now consider the integral needed for the calculation of the zero-mode contribution to the EM V:

$$I_2 = \int_{-L}^L \frac{dx}{x} \int_{-L}^L \frac{dk}{xk - b - ih + i0}; \quad (E 3)$$

where the principal value prescription for the pole at

$x = 0$ is implied. The real part of I_2 is found by direct integration:

$$\begin{aligned} \text{Re} I_2 &= \int_{-L}^L \frac{dx}{x} \text{P.V.} \int_{-L}^L \frac{dk}{xk - b - ih} \\ &= \int_{-L}^L \frac{dx}{x^2} \log \frac{xL - b - ih}{xL + b + ih} \\ &= \frac{4h}{L} + O\left(\frac{h^3}{L^3}\right): \end{aligned}$$

We have expanded the result in a series in powers of h/L , retaining the leading term only. Note that according to our prescription we should first tend L to infinity, while keeping finite, and then tend h to zero. Under such a convention, we obtain $\text{Re} I_2 = 0$. The imaginary part of I_2 reads

$$\begin{aligned} \text{Im} I_2 &= \int_{-L}^L \frac{dx}{x} \int_{-L}^L dk (xk - b - ih) \\ &= \int_{-L}^L \frac{dx}{x^2} \int_{-L}^L dx (xL - b - ih) \text{sgn}(y) \\ &= \frac{2h}{b}: \end{aligned}$$

Finally,

$$I_2 = \frac{2ih}{b}:$$

From the results obtained above it is easy to derive the following expressions for the generalized integrals

$$I_1 = \int_{-L}^L dx f(x) \int_{-L}^L \frac{dk}{xk - b - ih + i0} \quad (E 4)$$

$$= 2 \text{sgn}(b) + 2i \log \frac{L}{|b|} - \log \frac{1}{|b|} f(0);$$

$$I_2 = \int_{-L}^L \frac{dx}{x} f(x) \int_{-L}^L \frac{dk}{xk - b - ih + i0} \quad (E 5)$$

$$= \frac{2ih}{b} f(0)$$

$$+ 2 \text{sgn}(b) + 2i \log \frac{L}{|b|} - \log \frac{1}{|b|} f^0(0);$$

where $f(x)$ is an arbitrary function supposed to be smooth and finite at $x = 0$.
