Vacuum structure of CP^N sigm a models at =

M . A sorey and F. Falceto Departamento de F sica Teorica. Facultad de Ciencias Universidad de Zaragoza. 50009 Zaragoza. Spain

Abstract

We show that parity symmetry is not spontaneously broken in the \mathbb{CP}^N sigm a model for any value of N when the coe cient of the {term becomes = (mod. 2). The result follows from a non-perturbative analysis of the nodal structure of the vacuum functional $_0(z)$. The dynamical role of sphalerons turns out to be very important for the argument. The result introduces severe constraints on the possible critical behavior of the models at = (mod. 2).

Typeset using REVT_EX

The e ect of a CP-violating -term interaction on the infrared behavior of quantum eld theories generates substantial changes in the low energy spectrum [1]. For this reason, phenom elogical requirements in pose severe bounds on the actual value of the -parameter. The analysis of the response of the system s to such a topological perturbation is, however, a very rich source of information on the vacuum structure of the quantum system s at = 0 [2]. This structure is very hard to analyze by direct methods because it entirely dwells on the strong coupling regime and involves deep non-perturbative behaviors. The most relevant changes appears at = (m od 2). In this case the classical lagrangian is also CP invariant as in absence of the {term, $= 0 \pmod{2}$, but the behavior of the system is completely di erent in these two regimes.

QCD, the archetype of such systems, is still inaccessible for analytic studies of its prominent physical elects: con nem ent and chiral symmetry breaking. CP^N sigma models share many similar features like dynamical mass generation, con nem ent and asymptotic freedom, but they are simpler to analyze. In particular for some of those models there is exact analytic information on their quantum spectrum. It is, therefore, interesting to analyze the {vacuum elects in those systems in order to gain some insights into the similar elects in QCD_{3+1} .

The simplest model, $\mathbb{C}P^1$, is integrable for = 0 and =, the only two values of for which the system is classically CP invariant. However, the behavior of the system is very di erent in those cases. At = 0 the system is con ning and exhibits a mass gap; at = the model is massless and its critical exponents are those of SU (2) W ess-Zum ino-W itten conform al invariant model at level 1 [3,4]. In both cases the CP symmetry is not spontaneously broken. In the second case this can be rigorously shown in a discrete regularization of the model where it turns out to be equivalent to a spin $\frac{1}{2}$ chain by H aldane transform ation [5]; for those chains the Lieb-Schulz-M attis theorem [6] establishes that there are only two possibilities: either parity is spontaneously broken and there is a mass gap or the theory is gapless and parity is not spontaneously broken. Since it is known that the mass gap is zero for = [3][[5] [7], then parity is not spontaneously broken.

For higher values of N the integrability of the $\mathbb{C}P^N$ model is lost and the only nonperturbative information comes either from large N [8] and strong coupling expansions [9] or M onte C arb numerical simulations [10]{ [14]. Strong coupling expansions indicate at leading order the existence of rst order phase transition at = accompanied by a spontaneous symmetry breaking of parity. Large N expansions show that there is a non-vanishing mass gap at = and at leading order also foresee a similar critical behavior. A lthough large N and strong coupling limits do not commute [15] the scenarios emerging from both approximations are compatible. Moreover, it has been conjectured that this kind of critical behavior holds for all models with n > 1. Numerical M onte C arbo calculations pointed out the appearance of another unexpected rst order transition for lower values of < in the CP³ model [11]. However, the interpretation of the calculations is not completely clear because of the existence of large errors in the region near = which make M onte C arbo results not very reliable [14].

The aim of this letter is to shed some new light into the behavior of $\mathbb{C}P^{\mathbb{N}}$ models at = by a novel method which was successfully introduced for a similar problem in QCD. The method is based on the analysis of the nodal structure of the vacuum functional of the theory. In QCD ₃₊₁ and QED ₁₊₁ (with an external gauge invariant perturbation) those nodes appear for = at some classical gauge con gurations which include sphalerons [16] [17]. In both cases parity is not spontaneously broken [16] [17]. In QCD_{2+1} with a Chem-Sim ons m assive perturbation nodes also appear at con gurations with m agnetic charge [18]. It has been conjectured that those nodal con gurations play a relevant role for the con nem ent m echanism of those theories in absence of the topological perturbations. The generalization of those m ethods for the CP^Nm odels is quite straightforward but requires a detailed analysis.

The basic { eld variable is a complex eld z(x) with values in d^{N+1} constrained by the condition $z^{y}z = 1$. In the tem poral gauge, $A_{0} = \frac{i}{2}[z^{y}@_{0}z \quad (@_{0}z^{y})z] = 0$, the dynamics of the theory is governed by the quantum H am iltonian, which in Schrödinger representation reads

$$H = \frac{g^2}{2} \frac{Z}{z} \frac{dx}{z} \frac{1}{z^y(x)} \frac{i}{2} e^z \frac{1}{z(x)} + \frac{i}{2} e^z z^y + \frac{1}{2g^2} dx (D z)^y D z; \qquad (1)$$

where $0 = 0_x$ and D = 0 $[z^y 0 z (0 z^y) z]=2$. Physical states must satisfy the Gauss law constraint

$$z_{-x} = z_{-x}^{y} = z_{-x}^{y}$$
 ph (z) = 0: (2)

This means that $_{\rm ph}(z) = _{\rm ph}(z)$ for any U (1) gauge transformation z(x) = z(x)(x), with $= e^{i'(x)}$, i.e. physical states must be invariant under U (1) gauge transformations. Therefore, they can be identified with functionals on the quotient space P = =G of the space of 1-dimensional - elds by the group G of U (1) gauge transformations.

The quantum theory presents ultraviolet divergences which require renorm alization of the – elds z and the coupling constant g. It is, therefore, necessary to introduce an ultraviolet regularization in the H am iltonian (1). We shall consider the regularization [19]

$$H^{reg} = \frac{g^2}{2} \frac{Z}{dx} \frac{1}{z^y(x)} \frac{i}{2} e^{iz}$$

$$I \frac{D^2}{z^2} \frac{\pi}{z(x)} + \frac{i}{2} e^{iz}$$

$$+ \frac{1}{2g^2} \frac{dx}{dx} (Dz)^y Dz;$$
(3)

which preserves most of the symmetries of the model and is similar to that introduced for gauge theories in Ref. [20]. In both cases the Schrödinger formalism of the the quantum theory remains ultraviolet nite.

The non-trivial e ect of the {term is due to the non-simply connected character of the orbit space $_1(\mathbb{P}) = \mathbb{Z}$ or what is equivalent the non-connected character of the group of gauge transformations $_0(G) = \mathbb{Z}$. The regularized H am iltonian can be written as

$$H^{reg} = \frac{g^2}{2}^{Z} dx D_{z^{y}} I + \frac{D^2}{2}^{n} D^{z} + \frac{1}{2g^2}^{Z} dx (D z)^{y} D z;$$

where

$$D_{z} = \frac{1}{z} + \frac{1}{2} \partial z^{y} \qquad D_{z^{y}} = \frac{1}{z^{y}} - \frac{1}{2} \partial z; \qquad (4)$$

is a functional covariant derivative with respect to the U(1) ultra-gauge eld de ned over the space of sigm a elds by the ultra-gauge at vector potential

$$z = \frac{1}{2} \Theta z^{y} \qquad z^{y} = \frac{1}{2} \Theta z^{z}$$
(5)

The projections of the action of the operators D_{z^y} and D_z on gauge invariant functionals become covariant derivatives over P with respect the non-trivial at connection dened by the projection of on P. Now since the space of gauge orbits of eld congurations P is not simply connected, the elect of the {term becomes non-trivial because it cannot be removed by any smooth gauge transformation for any value of € 2 n. This happens because the projection of the potential (1=) is a generating form of the non-trivial rst cohomology group H¹(P;Z) = Z of P. In this sense the phenomenon is very similar to the A haranov-Bohm elect [20].

It is, however, possible to remove the dependence of the Ham iltonian by means of a singular gauge transformation $(z) = e^{\frac{i}{2}W(z)} p_h(z); w$ ith

$$W(z) = \frac{1}{2}^{Z} dx z^{y} @z:$$
 (6)

The transform ation yields a {independent H am iltonian $\mathbf{ff}^{\text{reg}} = e^{\frac{i}{2} W(z)} H^{\text{reg}} e^{\frac{i}{2} W(z)} = H_0^{\text{reg}}$; but it does not preserves G auss law because W is not invariant under large gauge transformations with non-trivial winding number (), W (z) = W (z) + 2 (). In other words,

is not globally de ned on P. It is, however, possible to gauge x the symmetry under global gauge transformations and nd an open domain $_0 = fz 2$; < W(z) < +)g in the space of eld con gurations such that any other eld con guration z(x) is gauge equivalent to one which lies in the topological closure $_0$ of $_0$. is uniquely de ned in $_0$ and only breaks global gauge invariance at the boundaries (0) = fz 2; W(z) = g, because for any pair of elds z 2 (0 and $z_+ 2$ (0_+ 0 which are gauge equivalent $z_+ = z$

by a gauge transform ation with winding number () = 1, e.g. $_{1}(x) = e^{2i \arctan (x=2a)}$. The dependence of the systems is now encoded by the non-trivial boundary conditions that physical states have to verify at the boundaries e_{0} and e_{+0} of $_{0}$,

In this sense the transform ation is trading the {dependence of the H am iltonian by non-trivial boundary conditions on Q_+_0 . The projection of the boundaries Q_-_0 into P de ne a codim ension one submanifold N which intersects any non-contractible loop of P. This explains why within this gauge xing fram ework it is possible to remove the {dependence of the system.

C lassical constant vacua con gurations $z_{vac}(x) = z_0$ belong to the dom ain $_0$, and are gauge equivalent to any other vacua classical con guration $z_{vac}^0 = z_0$ (x). In the boundary of $_0$ there are sphalerons z_{sph} and anti-sphalerons e_{sph} , which are quasi-stable static solutions of the classical motion equations with only one unstable direction. They can exist only for nite volum es. The explicit expression for the rst sphaleron on a nite circle S¹ is given by the sigm a eld con guration induced by the 2-dimensional instanton on the circle centered at the center of the instanton [21] and with radius a equal to the size of the instanton [22]

. In stereographic projection of polar coordinates it reads $z_{sph}(x) = (u + ve^{2i\arctan(x=2a)}) = \frac{p}{2}$ for any pair u and v of orthogonal unit vectors of \mathbb{C}^{N+1} , i.e. $u^{y}u = v^{y}v = 1$ and $u^{y}v = 0$. The unstable m ode corresponds to the radial dilation generated by the ow of the instanton. For in nite volume those con gurations are not anymore saddle points of the potential term

$$V(z) = \frac{1}{2q^2} \int dx (D z)^{y} D z:$$
 (7)

However, the other relevant property of sphalerons, W $(z_{sph}) = (z_{sph} \ 2 \ 0_{+} \ 0)$, remains independent of the space volume because the W (z) functional is metric independent. In particular, this means that $z_{sph} \ 2 \ 0_{+} \ p^{0}$. The conguration generated by the anti-instanton ow e_{sph} (x) = $(u + ve^{2iarctan(x=2a)}) = \overline{2}$ in $0 \ 0$ also exhibits similar properties.

There is another interesting feature of these two con gurations. The U (N+1) transform ation S_u^v which rotates on the plane de ned by u and v and interchanges u and v, transforms the anti-sphaleron \mathbf{e}_{sph} into a con guration which is gauge equivalent to the sphaleron, $S_u^v \mathbf{e}_{sph} = z_{sph}^{-1}$ by a gauge transform ation $_1(\mathbf{x}) = e^{2i \arctan(\mathbf{x}=2a)}$ with winding number ($_1$) = 1. The non-trivial boundary conditions induced by the singular gauge transform ation into physical states in ply that $(z_{sph}) = e^{-i}$ ($S_u^v \mathbf{e}_{sph}$) for any sphaleron conguration.

The theory is form ally CP invariant only for = 0 and = (m od 2). This can be seen from the behavior of the boundary condition under CP which reverses the sign of because the W (z) functional is CP odd. At = the boundary condition, how ever, becomes an antiperiodic boundary condition, $(z_{+}) = (z)$ which is CP invariant. Because of U (N+1) invariance the same property holds for the idem potent transform ation $P_s = S_u^v P$.

The behavior of sphalerons and classical vacuum con gurations under the P_s symmetry is rather di erent. The constant classical vacuum $z_{vac} = z_0 = cte$ is P invariant $(z_{vac}^{P} = z_{vac})$, but transforms under P_s into another classical vacuum con guration $z_{vac}^{P_s} = S_u^v z_{vac}$. The sphaleron is not parity invariant, but it is transformed by P_s into a gauge equivalent con guration, i.e. $z_{sph}^{P_s} = S_u^v e_{sph} = z_{sph}^{-1}$, with (1) = 1. In fact, the whole submanifold N 2 P is P_s invariant, but the sphaleron has an additional peculiarity, it is quasi-invariant under this transform ation.

In the full H ibert space H of all physical states which satisfy the anti-periodic boundary condition, there is always a complete basis of stationary wave functionals with a denite P_s symmetry. If an energy level is not degenerate the corresponding physical state (z) has to be P_s even or P_s odd. In the degenerate case, if U (P_s) (z) is not on the same ray that (z), the stationary functionals (z) = (z) U (P_s) (z) are P_s even/odd, respectively. If P_s is spontaneously broken the quantum vacua $_0$ (z) will not have a denite P_s parity ($_0 \in$) in the dimensional phases and the H ibert space will split into superselection sectors not connected by local observables.

Now, it is easy to show that anti-periodic boundary conditions in ply the existence of nodes in physical states with a de nite P_s parity. A ctually, since $U(P_s)_0(z_{sph}) = 0$ (e_{sph}) = $0(z_{sph})$; if the vacuum state is P_s even this is possible only if 0 vanishes for sphaleron con gurations, $0(z_{sph}) = 0$. Odd functionals with respect to P_s parity change sign from z_0 to $P_s z_0$, because $U(P_s)_0(z_0) = (z_0^{P_s}) = (z_0)$. Therefore, by continuity, they have to vanish for some constant classical vacua. If a quantum vacuum is odd this means that it vanishes for all classical vacua because of the U(N+1) invariance in plied by the

Colem an Merm in Wagner theorem. Now the potential term of the Hamiltonian V (z) gives a nite positive contribution to the energy of stationary states. The variation of V along the trajectory of classical con gurations de ned by the ow of an instanton which interpolates between the sphaleron = a and the classical vacua = 0 or = 1, given by

V (z) =
$$\frac{a^2}{2q^2} \frac{a^2}{(a^2 + a^2)^2}$$

indicates that the P_s even ground states which vanish at sphalerons cannot have the same energy as P_s odd states which vanish at classical vacuum con gurations where the potential term s attains its minimal value. Specially because the result holds for any value, weak or strong, of the coupling constant g^2 . Notice that in the regularized theory there is no running of the coupling constant and, then, the potential term of the H am iltonian is not suppressed in the infrared.

This feature implies that the quantum vacuum state $_0(z)$ has to be even under P_s parity, it has to vanish at sphaleron con gurations, ($_0(z_{sph}) = 0$), and the P_s symmetry is not spontaneously broken in the regularized theory.

On the other hand because of U (N + 1) invariance the vacuum functional $_0$ can never be odd under S_u^v parity. As a consequence $_0$ has to be even under P parity. The argument for P_s odd states applies also for the theory at = 0 and show s why parity is not spontaneously broken in that case too, where the quantum ground state is expected to have no nodes.

The vanishing of the quantum vacuum functional $_0$ for sphalerons, is basically based on two properties of those con gurations: its quasi-invariance under P_s parity and the special value that W functional reaches at them, W (z_{sph}) = . The arguments can be extended for any gauge eld satisfying the same properties. The in nitesimal perturbations $z = z_{sph} + + 0$ (2) of z_{sph} given by (x) = S_u^v ! (x) + ! $_1$ (x) + i z_{sph} (x)' (x) preserve both properties, for any perturbation of the { elds ! and any in nitesimal gauge transform ation '. Therefore they generate an in nite subspace of nodal con gurations for $_0$ in $Q_+ _0$. The same con gurations are also nodes of any higher energy stationary states with even P_s { parity $_{even}(z_{sph}) = 0$. In a similar way it can be shown that the nodal con gurations of P_s { parity odd excited states contain classical vacuum con gurations $_{odd}(z_{vac}) = 0$. The same results are obtained by a path integral analysis along the lines developed in R ef. [16].

The existence of those nodes for any value of the ultraviolet regulator and the coupling constant g, in plies that they also hold in the renormalized theory. The absence of spontaneous breaking of the sym metry also persists in the renormalized theory because the phenomenon is always related to the infrared properties of the theory which are the same for the regularized and renormalized theories. A ctually, the regularization of the kinetic term always enhances the role of smooth congurations and then the appearance of rst order transitions, and since they do not appear at = in the regularized theory, the cannot reappear when the ultraviolet regulator is removed. For the CP^1 model this is in perfect agreement with the exact results [3]{ [7], which also show that CP is not broken and there is no rst order transition. This behavior is also con rm ed by M onte C arlo simulations [10]. However, the main interest of the results resides in their application for N > 1 m odels where the predictions were not form erly known, although they are compatible with some recent M onte C arlo simulations [14]. In particular, they suggests that the observed smoothing of the free energy at = is not entirely due to the nite volume e ects but to the nite

coupling e ects of the potential as has been observed in 2-dimensional QED in the presence of an external perturbation [17]. This e ect can also be understood in the strong coupling expansion [9]. The cusp due to the level crossing of lowest energy states is removed by the level repulsion generated by the potential term at rst order in the strong coupling expansion in terms of degenerated perturbation theory [17].

All the above arguments conm that CP symmetry is preserved at = and exclude the existence of a rst order phase transition at = . However, the analysis does not give any clue on the existence or not of a second order phase transition at = . There are two possibilities: i) Non-existence of phase transition and only a crossover phenomena from around = ii) Existence of a second order phase transition. The later e ect is what actually occurs in the case $\mathbb{C}P^1$. One very plausible conjecture is that there is critical N = N_c (N_c=1?) such that the $\mathbb{C}P^N$ system undergoes a second order phase transition at = for N N_c and no transition for N > N_c where there is nite mass gap. Further numerical investigations of this a problem would be very interesting to clarify the behavior of the di erent regimes of the $\mathbb{C}P^N$ models around = .

W e thank K.G aw edzki and G.Sierra for discussions. This work was partially supported by CICyT grant AEN 96-1670.
