Septem ber, 2005

A bstract
In this expository paper we ilhustrate the generality of gam e theoretic probability protocols of Shafer and Vovk (2001) in nite-horizon discrete gam es. By restricting ourselves to nite-horizon discrete gam es, we can explicitly describe how discrete distributions w ith nite support and the discrete pricing form ulas, such as the $C$ ox-R oss $R$ ubinstein form ula, are naturally derived from gam e-theoretic probability protocols. C orresponding to any discrete distribution with nite support, we construct a nitehorizon discrete gam e, a replicating strategy of Skeptic, and a neutral forecasting strategy of Forecaster, such that the discrete distribution is derived from the gam e. Construction of a replicating strategy is the same as in the standard arbitrage argum ents of pricing European options in the binom ial tree m odels. H ow ever the gam e theoretic fram ew ork is advantageous because no a priori probabilistic assum ption is needed.

K eywords and phrases: binom ial distribution, $C$ ox-R oss $R$ ubinstein form ula, hypergeom etric distribution, low er price, P olya's distribution, probability protocol, replicating strategy, upper priae

## 1 Introduction

In the gam e theoretic probability of Shafer and Vovk (2001), probability distributions and probability m odels are not assum ed a priori but derived as logical consequences of certain protocol of a gam e betw een two players \Skeptic" and \R eality". In this gam e Skeptic tries to becom e rich by exploiting pattems in the m oves of Reality. In order to prevent Skeptic from becom ing rich, Reality is in a sense foroed to behave probabilistically. Therefore probability distributions are determ ined by the protocol of the gam e. This feature of the gam e theoretic probability is well ilhustrated by Shafer and V ovk (2001) in
their derivation of Skeptic's strategy forcing the strong law of large num bers (C hapter 3) and the derivation ofB lack-Scholes form ula (C hapter 9). A lso in Takeuchi's exposition of the gam e theoretic probability and nance (Takeuchi (2004)) this point is discussed w ith $m$ any interesting exam ples. Recently $K u m$ on and Takem ura (2005) gave a very sim ple strategy forcing the strong law of large num bers.

In the standard stochastic derivation of option pricing form ulas, em pirical probability is assum ed rst, but then by arbitrage argum ents, the em pirical probability is replaced by the risk neutral probability and the price of an option is given as the expected value w ith respect to the risk neutral probability. The risk neutral probability is often explained as a purely operational device usefiul in expressing the option price in a convenient form . On the other hand in the gam e theoretic probability the risk neutral probability is $m$ ore substantial, in the sense that Reality is foroed to behave according to the risk neutral probability to avoid arbitrage by Skeptic. W e should mention here that in Shafer and Vovk (2001) \forcing" is used only for in nite-horizon gam es. In this paper we som ew hat inform ally use the word to $m$ ean that Reality should avoid arbitrage by Skeptic in the setting of nite-horizon gam es.

A dditional exibility of gam e theoretic probability is gained by introducing the third player \Forecaster" into the gam e. At the beginning of each round Forecaster sets the price for R eality's m ove. By appropriately specifying the strategy of Forecaster, R eality's m oves can be forced to follow any prespeci ed distribution.

In this paper we dem onstrate the above features of the gam e theoretic probability in the setting of nitehorizon discrete gam es. For expository purposes we start with the sim plest setting of the coin-tossing gam e and derive binom ial distribution in Section 2 and give an analogous derivation of the CoxRossRubinstein form ula in Section 3. We discuss derivation of hypergeom etric distribution and Polya's distribution in Section 4 in order to illustrate the role of Forecaster. Then in Section 5 we discuss derivation of an arbitrary discrete distribution with nite support. M ultivariate extension is given in Section 6. Som e prelim inary $m$ aterial on gam e theoretic probability is given in A ppendix.

## 2 D erivation of binom ial distribution

C onsider the nite-horizon fair-coin gam e in Section 6.1 of Shafer and Vovk (2001). Its protocol is given as follow $s$.

Fair-Coin Game
Protocol:
$\mathrm{K}_{0}=$ : given
FOR n = 1;:::; N
Skeptic announces $M_{n} 2 R$.
Reality announces $x_{n} 2 f 1 ; 1 g$.
$K_{n}:=K_{n}+M_{n} X_{n}$.
END FOR
In this protocola gam e theoretic version of C hebyshev inequality is proved in (6.9) of

S\& V in the follow ing form :

$$
\underline{P} \quad \frac{S_{N}}{N} \quad 1 \quad \frac{1}{N^{2}} ;
$$

where $S_{N}=x_{1}+\quad \frac{1}{}$ and $\underline{P}$ denotes the low er probability. A ctually the equality of the upper probability and the low er probability

$$
\begin{equation*}
\underline{P} \quad \frac{S_{N}}{N} \quad=P \quad \frac{S_{N}}{N} \tag{1}
\end{equation*}
$$

holds here and this probability is given by binom ial distribution. A though this fact is contained in a m ore general statem ent of Proposition 8.5 of $S \& V$, we give a full proof of this fact em ploying standard arbitrage argum ents.

In order to treat success probability p $1=2$, let us consider the follow ing biased-ooin gam e.

B iased-C oin G ame
P rotocol:
$K_{0}=2 \mathrm{R} ; \mathrm{a} ; \mathrm{b}>0$ : gíven
FOR n = 1;:::; N
Skeptic announces $M_{n} 2 R$.
Reality announces $x_{n} 2$ fa; bg.
$K_{n}=K_{n}+M_{n} x_{n}$.
END FOR

As above we write $S_{n}=x_{1}+\quad$ 古.xLet $S_{0}=0$. C onsider a random variable $x()=\left(S_{N}\right)$ which depends only on $S_{N}$ (European option). Then we have the follow ing basic result.

Theorem 2.1 The upper and the lower expected values of $\left(S_{N}\right)$ coincide and given by

$$
\left.E\left(\left(S_{N}\right)\right)=\underline{E}\left(\left(S_{N}\right)\right)=\begin{array}{llllll}
X^{N} & N  \tag{2}\\
m=0
\end{array} p^{m}\left(\begin{array}{llll}
1 & p
\end{array}\right)^{N} \quad m \quad\left(\begin{array}{ll}
m & (N
\end{array} \quad m\right) b\right) ;
$$

where $\mathrm{p}=\mathrm{b}=(\mathrm{a}+\mathrm{b})$ is the risk neutral probability.

P roof: The rst step of our proof consists of de ning a \candidate" price of the European option. In the second step we verify that the candidate price is actually the precise price, by constructing a replicating strategy.

Let $\left(n ; S_{n}\right), S_{n}=n b ;(n \quad 1) b+a ;::$ na, denote the price of $\left(S_{N}\right)$ at timen. We require $\left(n ; S_{n}\right)$ to satisfy the follow ing \partial di erence equation"

$$
\begin{equation*}
\left(\mathrm{n} ; \mathrm{S}_{\mathrm{n}}\right)=\mathrm{p}\left(\mathrm{n}+1 ; \mathrm{S}_{\mathrm{n}}+\mathrm{a}\right)+\mathrm{q}\left(\mathrm{n}+1 ; \mathrm{S}_{\mathrm{n}} \quad \mathrm{~b}\right) ; \quad 0 \quad \mathrm{n}<\mathrm{N} ; \tag{3}
\end{equation*}
$$

where $q=1 \quad p . N$ ote that (3) $w$ ith $p=1=2$ is a discrete version of the heat equation. $T$ he term inal condition for $\left(n ; S_{n}\right)$ is given by

$$
\begin{equation*}
\left(\mathbb{N} ; S_{N}\right)=\left(S_{N}\right) ; \quad S_{N}=m a \quad(\mathbb{N} \quad m) b ; m=0 ;::: ; \mathbb{N}: \tag{4}
\end{equation*}
$$

Starting w th the term inal condition (4) we can solve for ( $n ; S_{n}$ ) in (3) by backward induction $n=N \quad 1 ; N \quad 2 ;::: ; 0$. Then the intial value $(0 ; 0)$ is easily calculated as

$$
\begin{aligned}
& (0 ; 0)=p(1 ; a)+q(1 ; b) \\
& =p(p(2 ; 2 a)+q(2 ; a \quad b))+q(p(2 ; a \quad b)+q(2 ; 2 b)) \\
& =\mathrm{p}^{2}(2 ; 2 \mathrm{a})+2 \mathrm{pq}(2 ; \mathrm{a} \quad \mathrm{~b})+\mathrm{q}^{2}(2 ; 2 \mathrm{~b}) \\
& =\quad:: \text { : }
\end{aligned}
$$

N ow we describe a replicating strategy for ( $\mathrm{S}_{\mathrm{N}}$ ) w ith the the replicating initialcapital (0;0). Forn = 1;:::; N , let

$$
\begin{equation*}
M_{n}=\frac{\left(n ; S_{n 1}+a\right)\left(n ; S_{n 1} \quad b\right)}{a+b}: \tag{5}
\end{equation*}
$$

$N$ ote that $a+b$ can be w ritten as

$$
a+b=\left(\begin{array}{lll}
S_{n} 1
\end{array}+a\right)\left(\begin{array}{lll}
\left(S_{n}\right. & 1 & b
\end{array}\right):
$$

Therefore $M_{n}$ is the ratio of the increm ents of $\left(n ; S_{n}\right)$ and $S_{n}$ and is called the \delta hedge". W e now chedk that this $M_{n}$ gives a replicating strategy $P$. This can be con $m$ ed by forward induction. At the end of the rst round $n=1$,

$$
\begin{aligned}
(0 ; 0)+\mathrm{K}_{1}^{\mathrm{P}} & =(0 ; 0)+\mathrm{M}_{1} \mathrm{x}_{1} \\
& =(0 ; 0)+\frac{(1 ; \mathrm{a})(1 ; \mathrm{b})}{\mathrm{a}+\mathrm{b}} \mathrm{x}_{1} \\
& =\left(\begin{array}{l}
(0 ; 0)+\mathrm{q}((1 ; \mathrm{a}) \quad(1 ; \mathrm{b})) ; \text { if } \mathrm{x}_{1}=\mathrm{a} ; \\
(0 ; 0) \mathrm{p}((1 ; \mathrm{a}) \quad(1 ; \mathrm{b})) ; \text { if } \mathrm{x}_{1}=\mathrm{b}
\end{array}\right. \\
& =\left(\begin{array}{l}
(1 ; \mathrm{a}) ; \text { if } \mathrm{x}_{1}=\mathrm{a} ; \\
(1 ; \mathrm{b}) ; \text { if } \mathrm{x}_{1}=\mathrm{b} ;
\end{array}\right. \\
& =\left(1 ; \mathrm{S}_{1}\right):
\end{aligned}
$$

Sim ilarly at the end of round $n=2$, we have

$$
\begin{aligned}
(0 ; 0)+K_{2}^{P} & =\begin{aligned}
\left(2 ; S_{1}+a\right) ; & \text { if } x_{2}=a ; \\
\left(2 ; \mathrm{S}_{1} \quad \mathrm{~b}\right) ; & \text { if } \mathrm{x}_{2}=\mathrm{b} ; \\
& =\left(2 ; \mathrm{S}_{2}\right):
\end{aligned}
\end{aligned}
$$

Now by induction we arrive at

$$
(0 ; 0)+K_{N}^{P}=\left(\mathbb{N} ; S_{N}\right)=\left(S_{N}\right):
$$

W e have con $m$ ed that $M_{n}$ in (5) w ith the replicating initial capital (2) gives a replicating strategy for $\left(S_{N}\right)$. H ence the theorem holds by Proposition A. 1 in A ppendix.

In particular if we take

$$
\left(\mathrm{S}_{\mathrm{N}}\right)=\begin{array}{ll}
1 ; & \text { if } \mathrm{S}_{\mathrm{N}} \dot{\mathcal{F}} \mathrm{~N} \\
0 ; & \text { otherw ise; }
\end{array}
$$

we see that the equality holds in (1) and the probability is given by binom ialdistribution.
In this section we took Reality's m ove space as fa; bg. This is convenient in comparing $T$ heorem 2.1] w ith the $C$ ox $R$ oss $R$ ubinstein form ula in the next section. H ow ever for generalization of binom ial distribution to hypergeom etric distribution in Section 4, it is $m$ ore convenient to rescale $R$ eality's $m$ ove space to $f 0 ; 1 \mathrm{~g}$. Then we need to introduce the price $p$ for the \tidket" $x_{n}$. T he rescaled protocol is w ritten as follow $s$.
Rescaled B iased-C oin G ame
Protocol:
$K_{0}=; 0<p<1:$ given
FOR n = 1;:::; N
Skeptic announces $M_{n} 2 R$.
Reality announces $\mathrm{x}_{\mathrm{n}} 2 \mathrm{f0}$; 1 g .

$$
\mathrm{K}_{\mathrm{n}}:=\mathrm{K}_{\mathrm{n} 1}+\mathrm{M}_{\mathrm{n}}\left(\mathrm{x}_{\mathrm{n}} \quad \mathrm{p}\right) .
$$

END FOR

It is clear that the biased-ooin gam e and the rescaled biased-ooin game is equivalent by the a ne correspondence $x_{n} \$(a+b)\left(x_{n} \quad p\right) ; p=b=(a+b)$. In the rescaled version the expected value in (2) is sim ply w ritten as

$$
E\left(\left(S_{N}\right)\right)=\underline{E}\left(\left(S_{N}\right)\right)=X_{m=0}^{X^{N}} \quad \begin{align*}
& N  \tag{6}\\
& m
\end{align*} p^{m}(1 \quad p)^{N} m \quad(m):
$$

Furthem ore, since the increm ent of $S_{n}$ is nom alized to be 1, the replicating strategy in (5) is sim ply w ritten as

$$
\begin{equation*}
M_{n}=\left(n ; S_{n 1}+1\right) \quad\left(n ; S_{n 1}\right): \tag{7}
\end{equation*}
$$

It is also conceptually very im portant to consider the single step gam e i.e. the gam e w ith $\mathrm{N}=1$. N ote that each round n of the N step biased-oin game can be viewed as a single step gam e. In the single step gam e binom ial distribution reduces to a Bemoulli trial. This im plies that given the prioe $p$, R eality'sm ove $x_{n}$ for each round $n$ is exactly the sam e as a single B emoulli trialw ith success probability p. Furtherm ore this behavior of Reality is dictated solely by the value ofp, independently from the past moves $x_{1} ;::: ; x_{n} 1$ of $R$ eality. Therefore in the $R$ escaled $B$ iased-C oin $G$ am $e, R$ eality's $m$ oves $x_{1} ;::: ; x_{N}$ are independent Bemoullitrials.

## 3 D erivation of the $C$ ox $R$ oss $R$ ubinstein form ula

H ere we present a gam e theoretic form ulation and derivation of the $C$ ox $R$ oss $R$ ubinstein form ula ( C ox, R oss and R ubinstein (1979)), which is fully discussed in $m$ any introductory textbooks on option pricing (e.g., Shreve (2004), C hapter 2 of B axter and Rennie (1996), C hapter 8 ofC apinskiand Zastaw niak (2003)). O nce an appropriate gam e is form ulated, the rest of the argum ent is the sam e as in the previous section.

O ur protocol for $C$ ox $R$ oss $R$ ubinstein gam $e$ is as follow $s$.
Cox-Ross-Rubinstein Game
P rotocol:
So > 0;u> r>d>0: given
FOR $n=1 ;::: ; \mathrm{N}$
Skeptic announces $M_{n} 2 R$.
Reality announces $\mathrm{x}_{\mathrm{n}} 2 \mathrm{fu} ; \mathrm{dg}$.

$$
\begin{aligned}
& S_{n}:=S_{n} 1 \quad X_{n} . \\
& K_{n}:=K_{n}+M_{n}\left(\begin{array}{lll}
S_{n} & S_{n} & 1
\end{array}\right)+\left(\begin{array}{ll}
\mathrm{r} & 1
\end{array}\right)\left(\begin{array}{llll}
K_{n} & 1 & M_{n} S_{n} & 1
\end{array}\right) .
\end{aligned}
$$

END FOR

Here $K_{n} \quad M_{n} S_{n} 1$ is the am ount of risk less bond held by Skeptic for the round $n$ and $r 1$ is the xed riskless interest rate. A though by appropriate discounting we $m$ ay put $r=1$ w thout essential loss of generality (Section 12.1 of $S \& V$ ), here we leave the interest rate $r$ as in standard derivation of the $C$ ox $R$ oss $R$ ubinstein form ula. $p=\left(\begin{array}{ll}r & d\end{array}\right)=\left(\begin{array}{ll}u & d\end{array}\right)$ is called the risk neutral probability.

Let $\left(S_{N}\right)$ denote a payo function of a European option depending on $S_{N}$. C orresponding to $T$ heorem 2.1 we have the follow ing result.

Theorem 3.1 (the Cox-RossRubinstein form ula) $T$ he upper and the lower expected values of ( $\mathrm{S}_{\mathrm{N}}$ ) coincide and given by

$$
\begin{equation*}
E\left(\left(S_{N}\right)\right)=\underline{E}\left(\left(S_{N}\right)\right)={\frac{1}{r^{N}}}_{m=0}^{X^{N}} \sum^{N} p^{m}(1 \quad p)^{N} \quad m \quad\left(u^{m} d^{N} m^{m} S_{0}\right) ; \tag{8}
\end{equation*}
$$

where $p=\left(\begin{array}{ll}r & d\end{array}\right)=\left(\begin{array}{ll}u & d\end{array}\right)$ is the risk neutral probability.
Proof: As in the previous section we de ne $\left(n ; S_{n}\right)$ by backward induction. Put $\left(\mathbb{N} ; \mathrm{S}_{\mathrm{N}}\right)=\left(\mathrm{S}_{\mathrm{N}}\right)$ and forn $=\mathrm{N} \quad 1 ;::: ; 0$, de ne

$$
\left(n ; S_{n}\right)=\frac{1}{r} p\left(n+1 ; u S_{n}\right)+\left(\begin{array}{ll}
1 & p
\end{array}\right)\left(n+1 ; d S_{n}\right)
$$

Then the initial value $\left(0 ; S_{0}\right)$ is easily calculated as

$$
\left(0 ; S_{0}\right)={\frac{1}{r^{N}}}_{m=0}^{X^{N}}{ }^{N} \quad p^{m}(1 \quad p)^{N} \quad m \quad\left(u^{m} d^{N} \quad{ }^{m} S_{0}\right):
$$

This becom es the replicating initial capital of the follow ing replicating strategy:

$$
M_{n}=\frac{\left(n ; u S_{n-1}\right)\left(n ; d S_{n-1}\right)}{(u d) S_{n}}:
$$

Since the gam e is coherent by the requirem ent $u>r>d$, the theorem follow from P roposition $\mathbb{A} .1$.

## 4 H ypergeom etric distribution and P olya's distribution

In the rescaled biased-coin gam e of Section 2, the price $p$ of the tidket $x_{n}$ was a constant. $T$ herefore the third player \Forecaster" did not enter the protocol. $N$ ow we introduce Forecaster, who sets the price of the tidket at the beginning of each round in the rescaled biased-coin gam e. W e illustrate the role of Forecaster below by deriving the hypergeo$m$ etric distribution. W e also derive Polya's distribution.
Rescaled B iased-Coin Game W ith Forecaster
P rotocol:
$K_{0}=$ : given
FOR $\mathrm{n}=1$;:::; N
Forecaster announces $p_{n} 2 R$.
Skeptic announces $M_{n} 2 R$.
Reality announces $\mathrm{x}_{\mathrm{n}} 2 \mathrm{f0} ; 1 \mathrm{~g}$.
$K_{n}:=K_{n}+M_{n}\left(x_{n} \quad p_{n}\right)$.
END FOR
$N$ ote that ifForecaster announces $p_{n}>1$ or $p_{n}<0$, then Skeptic can becom e in nitely rich im $m$ ediately by taking $M_{n}$ jarbitrarily large. T herefore we can restrict them ove space ofForecaster to be $[0 ; 1]$. Furthem ore if $p_{n}=0$, Skeptic can stilltake $M_{n}$ arbitrarily large, which foroes R eality to choose $\mathrm{x}_{\mathrm{n}}=0$. Sim ilarly if $\mathrm{p}_{\mathrm{n}}=1$, then $R$ eality is forced to choose $\mathrm{x}_{\mathrm{n}}=1$.

N ow consider a strategy of Forecaster. A strategy ofForecaster is called neutral (Section 82 of $S \& V$ ) if $p_{n}$ is detem ined by the past $m$ oves ofR eality $x_{1}::: x_{n} 1$. From now on we only consider neutral strategies for Forecaster. Furthem ore for sim plicity we consider neutral strategy depending on $S_{n 1}=x_{1}+\quad$ it $x$ and write $p_{n}=p_{n}\left(S_{n} 1\right)$, which we $m$ ay call \M arkovian neutral strategy". In M arkovian neutral strategy Forecaster only needs to keep $S_{n} 1$ in $m$ em ory to choose his $m$ ove.

C onsider an um with 1 red balls and 2 black balls, where $1_{1}+2 \quad N$. Let $x_{n}=1$ correspond to draw ing a red ball and let $x_{n}=0$ correspond to draw ing a black ball from the um by R eality. Let $p_{n}$ be the ratio of red balls in the um at the $n$-th round. Then

$$
p_{n}=p_{n}\left(S_{n}\right)=\frac{\max \left(0 ; 1 \quad S_{n} 1\right)}{1+2(n \quad 1)}:
$$

A ctually here we do need to take the positive part of ${ }_{1} S_{n}$, , because as rem arked above once the boundary $S_{n}=1$ is attained, then $0=p_{n}=p_{n+1}=::$ : and Reality is forced to choose $0=x_{n}=x_{n+1}=:::$, which results in ${ }_{1}=S_{n}=S_{n+1}=:::$. N ow we w rite out a gam e of sam pling w thout replacem ent from an um.

Game of Sampling $W$ ithout Replacement From An Urn P rotocol:
$\mathrm{K}_{0}=;{ }_{1}>0 \boldsymbol{i}_{2}>0 \boldsymbol{i}_{1}+{ }_{2} \mathrm{~N}, \mathrm{~S}_{0}=0$ : given
FOR n = 1;:::; N
Forecaster announces $p_{n}=\left(\begin{array}{ll}1 & S_{n}\end{array}\right)=\left({ }_{1}+2 n+1\right)$
Skeptic announces $M_{n} 2 R$.
Reality announces $\mathrm{x}_{\mathrm{n}} 2 \mathrm{f0}$; 1 g .
$K_{n}=K_{n 1}+M_{n}\left(\mathrm{x}_{\mathrm{n}} \quad \mathrm{p}_{\mathrm{n}}\right)$.
$\mathrm{S}_{\mathrm{n}}:=\mathrm{S}_{\mathrm{n} 1}+\mathrm{x}_{\mathrm{n}}$.
END FOR
For this gam e the upper and the lower values of the payo ( $\mathrm{S}_{\mathrm{N}}$ ) coincide and are given by the expected value w ith respect to the hypergeom etric distribution:

$$
\begin{equation*}
E\left(\left(S_{N}\right)\right)=\underline{E}\left(\left(S_{N}\right)\right)=\operatorname{ming}(1 ; N)_{m=\max (0 ; N \quad 2)}^{(m) \frac{m^{1} N^{2}}{N_{N}^{1+2}}: ~} \tag{9}
\end{equation*}
$$

This result is actually alm ost obvious from the discussion at the end ofSection 2, nam ely, at each round $n$ Reality's $m$ ove $x_{n}$ is like draw ing a ball from an um $w$ ith $l_{1} S_{n}$ red balls and 2 (n 1 $\quad S_{n} 1$ ) black balls. H ow ever it is instructive to look at a form al proof of (9).

De ne a candidate price of $\left(\mathrm{S}_{\mathrm{N}}\right)$ at tim en by backw ard induction:

$$
\left(n ; S_{n}\right)=p_{n+1}\left(S_{n}\right)\left(n+1 ; S_{n}+1\right)+\left(1 \quad p_{n+1}\left(S_{n}\right)\right)\left(n+1 ; S_{n}\right) ; n=N \quad 1 ;::: ; 0 ;
$$

w ith the term inal condition $\quad\left(\mathbb{N} ; \mathrm{S}_{\mathrm{N}}\right)=\left(\mathrm{S}_{\mathrm{N}}\right)$. Then by fully expanding the recurrence relation we have

$$
\begin{aligned}
& \left.\left.(0 ; 0)=\quad \begin{array}{llllll}
\mathrm{X} & \mathrm{Y}_{\mathrm{N}}\left(\mathrm{~S}_{\mathrm{n}} 1\right.
\end{array}\right)^{\mathrm{X}_{\mathrm{n}}}\left(\begin{array}{llll}
1 & \mathrm{p}_{\mathrm{n}}\left(\mathrm{~S}_{\mathrm{n}}\right. & 1
\end{array}\right)\right)^{1} \begin{array}{l}
\mathrm{x}_{\mathrm{n}}
\end{array} \quad\left(\mathrm{~S}_{\mathrm{N}}\right): \\
& \begin{array}{c}
\left(\mathrm{x}_{1} ;::: ; \mathrm{x}_{\mathrm{N}}\right) 2 \mathrm{f0;1g}^{\mathrm{N}} \quad \mathrm{n}=1 \\
\max (0 ; \mathrm{N} \\
2)
\end{array}
\end{aligned}
$$

A ctually we dg not need the restriction m ax $\left(0 ; \mathrm{N} \quad{ }_{2}\right) \quad \mathrm{S}_{\mathrm{N}} \quad \mathrm{m}$ in $\left({ }_{1} ; \mathrm{N}\right)$ in the sum m ation, because ${ }_{n=1}^{N} p_{n}\left(S_{n} 1\right)^{x_{n}}\left(1 \quad p_{n}\left(S_{n} 1\right)\right)^{1} x_{n}=0$ for $S_{N}$ outside of this range. $N$ ow
it is easily seen that

$$
\begin{aligned}
& Y^{N} \\
& \mathrm{p}_{\mathrm{n}}\left(\mathrm{~S}_{\mathrm{n}} \quad 1\right)^{\mathrm{x}_{\mathrm{n}}}\left(1 \quad \mathrm{p}_{\mathrm{n}}\left(\mathrm{~S}_{\mathrm{n}} \quad 1\right)\right)^{1} \mathrm{x}_{\mathrm{n}} \\
& \mathrm{n}=1
\end{aligned}
$$

$$
\begin{aligned}
& =\frac{\frac{1!}{\left(1 S_{\mathrm{N}}\right)!(2(\mathbb{N})} \frac{(1+2)!}{(1+2 \mathrm{~N})!}}{\frac{(1+2)!}{(1)}}:
\end{aligned}
$$

Therefore
$N$ ow for a given value of $S_{N}$, the sum $m$ ation just counts the num ber of $w$ ays of choosing $S_{N} 1$ 's am ong $x_{1} ;::: ; x_{N}$. It follow $s$ that
which proves (9).
The above argum ent can be im m ediately applied to Polya's um m odel (Section V 2 of Feller (1968)). In this schem e, when a ball is drawn from an um, it is replaced and, $m$ oreover, $c$ balls of the sam e color are added. Then the gam e corresponding to Polya's um $m$ odeldi ers from the gam e of sam pling w thout replacem ent only in the speci cation of Forecaster's neutral strategy. In P olya's um m odel

$$
p_{\mathrm{n}}=\mathrm{p}_{\mathrm{n}}\left(\mathrm{~S}_{\mathrm{n}} 1\right)=\frac{1+\mathrm{CS} \mathrm{~S}_{\mathrm{n}} 1}{1+2+(\mathrm{n} 1) \mathrm{c}}:
$$

Then as in (2.4) of Section V 2 offeller (1968), the expected value of ( $\mathrm{S}_{\mathrm{N}}$ ) in this gam e is $w$ ritten as
where the binom ial coe cient $\underset{n}{r}$ for a realr and nonnegative integer $k$ denotes

$$
\begin{align*}
& \mathrm{r}  \tag{12}\\
& \mathrm{k}
\end{align*}=\frac{\mathrm{r}\left(\begin{array}{ll}
\mathrm{r} & 1
\end{array}\right) \quad\left(\begin{array}{ll}
\mathrm{r} & \mathrm{k}+1) \\
\mathrm{k}!
\end{array}{ }^{1}\right)}{}
$$

$N$ ote that (6) and (9) are special cases of (11) $w$ th $c=0$ and $c=1$, respectively. In (9) the range of sum $m$ ation can be taken as $m=0 ;::: ; N$, $w$ ith the convention (12).

## 5 A rbitrary discrete distribution w ith $n$ ite support

So far we have discussed how to derive som e classical distributions. W e now show that given any distribution on f0; :: :; N g, we can specify a neutralstrategy offorecaster in a gam e w ith N rounds such that $R$ eality follow s the distribution.

Let $q_{n} 0 ; m=0 ;::: ; N, \quad \stackrel{N}{m=0} q_{n}=1$, denote an arbitrary probability distribution on f0;:::; N g. By decreasing N if necessary, we assum e $\mathrm{q}_{\mathrm{v}}>0$. De ne

$$
q_{n}=\frac{q_{m}+\frac{\Delta}{} q_{m}+q_{n}+\quad m=1 ;::: ; N: ~}{N} ;
$$

Then

$$
\begin{equation*}
q_{n}=q_{1} \quad m\left(\Phi_{1} \quad q_{n+1}\right) ; \quad m=1 ;::: ; N ; q_{N+1}=0: \tag{13}
\end{equation*}
$$

Let

$$
\mathrm{p}_{\mathrm{n}}=\begin{array}{ll}
\left(\mathrm{q}_{\mathrm{n}} ;\right. & \text { if } \mathrm{S}_{\mathrm{n}} 1=\mathrm{n} \\
0 ; & \text { otherw ise: }
\end{array}
$$

The idea here is to let R eality increase $S_{n} \quad$ by 1 with probability $q_{1} 1$ if $S_{n}=n \quad 1$ or otherw ise let him stop at the current level for the rest of the rounds. N ote that $\mathrm{p}_{\mathrm{n}}=\mathrm{p}_{\mathrm{n}}\left(\mathrm{S}_{\mathrm{n}} \mathrm{I}_{1}\right)$ is indeed a function of $\mathrm{S}_{\mathrm{n}}$ 1, because it is written as

$$
p_{n}=q_{n} \quad I\left(S_{n} \quad=n \quad 1\right) ;
$$

where $I($ ) is the indicator function.
B iased-Coin Game W ith Forecaster For A rbitrary D istribution
P rotocol:

$$
\begin{aligned}
& K_{0}=, S_{0}=0, q_{n} 0 ; m=0 ;::: ; N, \quad{ }_{m}^{N}{ }_{m=0}^{N} q_{m}=1: \text { given } \\
& \text { FOR n = 1;:::;N } \\
& \text { Forecaster announces } p_{n}=q_{h} \quad I\left(S_{n} \quad=n \quad 1\right) \text {. } \\
& \text { Skeptic announces } M_{n} 2 R \text {. } \\
& \text { Reality announces } x_{n} 2 \text { f0;1g. } \\
& K_{n}: K_{n 1}+M_{n}\left(x_{n} \quad p_{n}\right) \text {. } \\
& S_{n}: S_{n 1}+x_{n} \text {. } \\
& \text { END FOR }
\end{aligned}
$$

The tree of this gam $e$ is illustrated in $F$ igure 1. For this gam e we have the follow ing result.

T heorem 5.1 The upper and the lower expected values of $\left(\mathrm{S}_{\mathrm{N}}\right)$ coincide and given by

$$
\begin{equation*}
\left.E\left(\left(S_{N}\right)\right)=\underline{E}\left(\left(S_{N}\right)\right)\right)^{X^{N}} \quad(m) \mathscr{I}_{m}: \tag{14}
\end{equation*}
$$

Figure 1: Tree of the gam e for arbitrary distribution

Proof: A s in the case of hypergeom etric distribution

$$
\begin{aligned}
& \mathrm{X} \quad \mathrm{Y}^{\mathrm{N}} \\
& (0 ; 0)=\quad \mathrm{p}_{\mathrm{n}}\left(\mathrm{~S}_{\mathrm{n}} 1\right)^{\mathrm{x}_{\mathrm{n}}}\left(1 \quad \mathrm{p}_{\mathrm{n}}\left(\mathrm{~S}_{\mathrm{n}} 1\right)\right)^{1 \mathrm{x}_{\mathrm{n}}}\left(\mathrm{~S}_{\mathrm{N}}\right): \\
& \left(\mathrm{x}_{1} ;:: ; \mathrm{x}_{\mathrm{N}}\right) 2 \text { for } 1 \mathrm{~g}^{\mathrm{N}} \mathrm{n}=1
\end{aligned}
$$

In this gam $e$, the path leading to $S_{m}$ is uniquely determ ined as

$$
x_{1}::: x_{N}=1::: 10::: 0
$$

$w$ th $m$ initial 1's. $B y$ (13), for this path $Q_{n=1}^{N} p_{n}\left(S_{n} 1\right)^{x_{n}}\left(1 \quad p_{n}\left(S_{n} 1\right)\right)^{1} x_{n}=q_{n}$. Therefore $(0 ; 0)=\underset{m=0}{N}(m) q_{m}$. The replicating strategy con $m$ ing this candidate price is given as

In $T$ heorem 5.1] we have considered a discrete distribution $w$ th the support $f 0 ;::: ; \mathrm{N} g$. $W$ e can dealw th the support of the form fa; $a+1 ;::: ; b g$, by letting $N=b$ a and setting the initial value $S_{0}=a$.

In Section 8.3 of their book, Shafer and Vovk discuss \adding tidkets" to make the upper expected value and the lower expected value to coincide. N ote that if Reality's $m$ ove space has $m$ ore than two elem ents in a single step gam $e$, then the upper expected value is generally larger than the low er expected value. Theorem 5.1 show $s$ that ifwe add su cient num ber of steps to a single step gam e, the equally of the upper and the low er prioes is achieved.

## 6 M ultivariate extension

In the previous sections we have considered univariate random variable $S_{N}$. In this section we give a straightforw ard $m$ ultivariate extension of the results of the previous sections. We
em ploy the m ulti-label classi cation protocoldiscussed in Vovk, N ouretdinov, Takem ura and Shafer (2005).

O ur extension corresponds to generalizing B inom ialdistribution to $m$ ultinom ialdistribution. Let $S_{N}=\left(S_{N}^{1} ;::: ; S_{N}^{d}\right)$ be a d-dim ensionalvector. A $s$ in $m$ ultinom ialdistribution, for the sake of sym $m$ etry, we leave one-dim ensional redundancy $N=S_{N}^{1}+\quad \frac{f}{N} \mathrm{Sn}$ the com ponents of $S_{N}$. Therefore $x_{n}$ in Rescaled B iased-C oin $G$ am e now corresponds to a 2 -dim ensional vector ( $x_{n} ; 1 \quad x_{n}$ ). For the generald-dim ensional case the $m$ ove space of Reality

$$
\mathrm{X}=\mathrm{fe} ; 1::: ; \mathrm{e}_{\mathrm{d}} \mathrm{~g}=\mathrm{f}(1 ; 0 ;::: ; 0) ;(0 ; 1 ; 0 ;::: ; 0) ;::: ;(0 ;::: ; 0 ; 1) \mathrm{l}
$$

consists of d standard coordinate vectors.
M ultilabel C lassification Game W ith Neutral Forecasting Strategy P rotocol:
$\mathrm{K}_{0}=, \mathrm{S}_{0}=0$ : given
FOR n = 1;:::; N
Forecaster announces $p_{n}=p_{n}\left(S_{n} \quad 1\right) 2 R^{d}$.
Skeptic announces $M_{n} 2 R^{d}$.
Reality announces $x_{n} 2 X$.
$K_{n}=K_{n} 1+M_{n} \quad\left(\begin{array}{ll}x & p_{n}\end{array}\right)$.
$\mathrm{S}_{\mathrm{n}}:=\mathrm{S}_{\mathrm{n} 1}+\mathrm{x}_{\mathrm{n}}$.
END FOR
Here \" denotes the standard inner product of R .
In the above protocolwe took the whole $R^{d}$ as the $m$ ove space of Forecaster. Let

$$
(X)=f\left(p^{1} ;::: ; p^{d}\right) j p^{i} \quad 0 ;{ }_{i=1}^{X^{d}} p^{i}=1 g
$$

denote the probability sim plex spanned by the standard coordinate vectors. IfForecaster announces $\mathrm{p}_{\mathrm{n}} \bar{Z}(\mathrm{X})$, then by the hyperplane separation theorem Skeptic can choose $M_{n} 2 R^{d}$ such that he becom es in nitely rich im $m$ ediately, no $m$ atter what $m$ ove Reality chooses. Se Vovk, N ouretdinov, Takem ura and Shafer (2005) for a discussion of this point. Therefore we can restrict Forecaster'sm ove space to the probability sim plex (X). A lso if $p_{n}^{i}=0$ for some i, Skeptic can choose $M{ }_{n}^{i}$ arbitrarily large and $R$ eality is forced to choose $x_{n}^{i}=0$.

W e also note that there is a redundancy in the $m$ ove space of Skeptic, once $p_{n}$ is restricted to lie in (X). $M_{n}+C(1 ;::: ; 1)$ for any $c 2 R$ leads to the same increm ent of the capital process $\mathrm{K}_{\mathrm{n}}$. H ow ever it is often convenient to ignore this redundancy in specifying Reality's m ove $M_{n}$.

For notational sim plicity w rite

$$
\left.p_{n}^{x_{n}}=\left(p_{n}^{1}\right)^{x_{n}^{1}} \quad \begin{array}{l}
d \\
n
\end{array}\right)\left(p_{0}^{d}=p_{n}^{i} \quad \text { for } x_{n}=e_{i}:\right.
$$

A sa straightforw ard generalization of results in the previous sections w e have the follow ing theorem.

Theorem 6.1 The upper and the lower expected values of $\left(S_{N}\right)$ coincide and given by

$$
E\left(\left(S_{N}\right)\right)=\underline{E}\left(\left(S_{N}\right)\right)=\sum_{\left(x_{1} ;:: ; X_{N}\right) 2 x^{N} n=1}^{X} Y_{n}^{N}\left(S_{n} 1\right)^{x_{n}}\left(S_{N}\right):
$$

The line of the proof is the sam e as in the previous theorem s and we om it the details. The price $\left(\mathrm{n} ; \mathrm{S}_{\mathrm{n}}\right)$ at timen is de ned recursively by

$$
\left(n ; S_{n}\right)=X_{i=1}^{X^{d}} p_{n+1}^{i}\left(S_{n}\right) \quad\left(n+1 ; S_{n}+e_{i}\right)
$$

and the replicating strategy $M{ }_{n}^{i}$ is sim ply given by

$$
M_{n}^{i}=\left(n ; S_{n} 1+e_{i}\right):
$$

From Theorem 6.1 we can easily derive multinom ial distribution, m ultivariate hypergeo$m$ etric distribution as well as $m$ ultivariate $P$ olya's distribution.

A generalization of $T$ heorem 5.1 to an arbitrary ( $d \quad 1$ )-dim ensional discrete distribution of ( $S_{N}^{1} ;:::: S_{N}^{d}{ }^{1}$ ) w ith nite support can be explained as follows. $W$ e rst use Theorem 5.1 on the rst com ponent $S_{n}^{1}$ to derive the one-dim ensionalm arginal distribution of $S_{N}^{1}$. Then, given the realization of the rst com ponent, we derive the conditional distribution of $S_{N}^{2}$ given $S_{N}^{1}$ by another application of $T$ heorem 5.1 to the second com ponent. W e can continue this process up to the ( d 1 )th com ponent. T he last com ponent $S_{n}^{d}$ is used as a slack variable.

Finally as an illustration of $T$ heorem 6.1 we show how the $C$ ox $R$ oss $R$ ubinstein form ula of Section 3 is reduced to our multivariate fram ew ork. De ne

$$
x_{n} \quad \frac{S_{n} \quad r S_{n} 1}{r^{n}}:
$$

Furtherm ore by discounting de ne

$$
K_{n} \quad \frac{K_{n}}{r^{n}}:
$$

Then the recurrence relation of the $C$ ox $R$ oss $R$ ubinstein gam e

$$
\begin{aligned}
K_{\mathrm{n}} & =K_{\mathrm{n} 1}+\mathrm{M}_{\mathrm{n}}\left(\mathrm{~S}_{\mathrm{n}} \mathrm{~S}_{\mathrm{n} 1}\right)+\left(\begin{array}{lll}
\mathrm{r} & 1
\end{array}\right)\left(\begin{array}{lll}
\mathrm{K}_{\mathrm{n}}^{1} & M_{\mathrm{n}} \mathrm{~S}_{\mathrm{n}} 1
\end{array}\right) \\
& =r K_{\mathrm{n} 1}+\left(\begin{array}{l}
S_{\mathrm{n}} \quad r S_{\mathrm{n}} 1
\end{array}\right) M_{\mathrm{n}}
\end{aligned}
$$

is w ritten as

$$
\mathrm{K}_{\mathrm{n}}=\mathrm{K}_{\mathrm{n} 1}+\mathrm{M}_{\mathrm{n}} \mathrm{x}_{\mathrm{n}}:
$$

Here $x_{n}$ can take two values

$$
\left.\left(x_{n}^{1} ; x_{n}^{2}\right)=\frac{S_{n 1}(u \quad r)}{r^{n}} ; \frac{S_{n} 1(d r}{r^{n}}\right):
$$

Rescaling the values we de ne $d=2, x_{n} 2 f e_{1} ; e_{2} g=f(1 ; 0) ;(0 ; 1) g$ and

$$
\begin{aligned}
M_{n} & =\left(x_{n}^{1} ; x_{n}^{2}\right) ; \\
\mathrm{p}_{\mathrm{n}} & =\frac{x_{n}^{2}}{x_{n}^{1} x_{n}^{2}} ; \frac{x_{n}^{1}}{x_{n}^{1} \quad x_{n}^{2}} ;
\end{aligned}
$$

$T$ hen $M_{n} x_{n}$ is written as

$$
M_{n} x_{n}=M_{n} \quad\left(\begin{array}{ll}
\mathrm{X} & \left.p_{n}\right):
\end{array}\right.
$$

$T$ herefore the iteration part of the the $C$ ox $R$ oss $R$ ubinstein gam $e$ is w ritten as
FOR n = 1;:::; N
Skeptic announces $M_{n} 2 R^{2}$.
Reality announces $x_{n} 2 f e_{1} ; e_{2} g$.

$$
K_{n}=K_{n 1}+M_{n} \quad\left(\mathrm{x} \quad \mathrm{p}_{\mathrm{n}}\right)
$$

END FOR
This show sthat the C ox R ossR ubinstein form ula is also a special case of our multivariate extension.

## A Prelim inaries on gam e theoretic probability

H ere we sum $m$ arize prelim inary $m$ aterial (C hapter 1 ofS\& $V$ ) of the gam e theoretic probability. We also state a basic proposition on the existence of a replicating strategy and the existence of the gam e theoretic expectation in a coherent gam e.

In this paper all the gam es are nitehorizon gam es $w$ th $N$ rounds. Therefore a path of the game is a nite sequence $=x_{1}::: x_{N}$ of $R$ eality's $m$ oves. A random variable $\mathrm{x}($ ) denotes a payo to Skeptic, when R eality chooses the path. $G$ iven a strategy $P$ of Skeptic, $K^{P}$ denotes the capital process ofP w ith zero initialcapital. Furtherm ore in this paper we only consider sym $m$ etric gam es, in the sense that if $P$ is a strategy of Skeptic, then $P$ is also a strategy of Skeptic and

$$
K^{\mathrm{P}}=\mathrm{K}^{\mathrm{P}}:
$$

The upper expected value Ex and the lower expected value Ex of x is de ned as

$$
\begin{aligned}
& \text { Ex }=\text { inff } j 9 P ; 8 ; K_{N}^{P}() \quad x() \quad g ; \\
& \underline{E}=\operatorname{supf} j 9 P ; 8 ; K_{N}^{P}() \quad x() g:
\end{aligned}
$$

In a sym $m$ etric gam e Ex can also be written as

$$
\begin{equation*}
\underline{E} x=\operatorname{supf} j 9 P ; 8 ;+K{ }_{N}^{P}() \quad x() g: \tag{16}
\end{equation*}
$$

A gam e is coherent if Skeptic is not allowed to $m$ ake $m$ oney for certain, i.e.,

$$
8 P ; 9 ; K_{N}^{P}()<0:
$$

If a gam e is coherent, then Ex Ex for every random variable $x$ (Proposition 72 of S\& V).

We calle a replicating strategy for x w ith the replicating initial capital 2 R if

$$
+\mathrm{K}_{\mathrm{N}}^{\mathrm{P}}(\mathrm{)}=\mathrm{x}(\mathrm{)}) 8 \text { : }
$$

W e now state the follow ing basic fact.
P roposition A. 1 In a coherent sym $m$ etric gam e, suppose that P is a replicating strategy for x w ith the replicating in itial capital. Then

$$
E x=\underline{E} x=:
$$

Proof: By de nition of Ex we have Ex . Furtherm ore in a sym m etric game Ex follows from (16). Therefore Ex Ex. C ombining this w ith the inequality Ex Ex we obtain the proposition.

We should note that the proof of the inequality Ex Ex in S\& V and the above proof are standard arbitrage argum ents.

A cknow ledgm ent. W e are grateful for insightful com $m$ ents by $V$ ladim ir $V$ ovk, $G$ lenn Shafer, $K$ ei Takeuchi and M asayukiK um on on earlier drafts of this paper.
