Abstract

The best fit line from minimizing the sum of the squared perpendicular error is given.

1 Introduction

With simple linear regression and data $(x_1, y_1), \dots, (x_n, y_n)$, we will minimize the sum of the squared vertical errors to find the "best-fit" line.

2 Minimizing Squared Perpendicular Errors

For a right triangle with legs a, b and hypotenuse c with h the distance from the intersection of the legs to the hypotenuse. From similar triangles $a=h=c=b$; so $h^2 = (ab)^2 = (a^2 + b^2)$. The sum of the squared perpendicular errors SSE_p for the fitted line $h(x) = b_0 + b_1x$ has

$$SSE_p(b_0, b_1) = \sum_{i=1}^n \frac{(y_i - b_0 - b_1x_i)^2 (x_i - (y_i - b_0) = -b_1)^2}{(y_i - b_0 - b_1x_i)^2 + (x_i - (y_i - b_0) = -b_1)^2} \quad (1)$$

with

$$\frac{\partial}{\partial b_0} SSE_p(b_0, b_1) = \frac{2}{b_1^2 + 1} \sum_{i=1}^n x_i + n b_0 \sum_{i=1}^n y_i \quad (2)$$

with root

$$b_0 = \bar{y} - b_1 \bar{x} \quad (3)$$

as in the simple linear regression case

Set $S_{xx} = \sum_{i=1}^n (x_i - \bar{x})^2$, $S_{yy} = \sum_{i=1}^n (y_i - \bar{y})^2$, $S_{xy} = \sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y})$.
 With b_0 from Equation 3,

$$SSE_p(b_1) = \frac{S_{yy} - 2b_1S_{xy} + b_1^2S_{xx}}{1 + b_1^2}; \quad (4)$$

and the equation for the slope b_1 is given by

$$\frac{\partial}{\partial b_1} SSE_p(b_1) = \frac{2 \left(\frac{1}{n} S_{xy} + b_1 (S_{xx} - S_{yy}) - S_{xy} \right)}{(1 + \frac{1}{n})^2} \quad (5)$$

with roots (provided $S_{xy} \neq 0$)

$$b_1 = \frac{S_{yy} - S_{xx}}{2S_{xy}} \pm \frac{\sqrt{(S_{yy} - S_{xx})^2 + 4S_{xy}^2}}{2S_{xy}} \quad (6)$$

If $S_{xy} \neq 0$; then there are two roots from Equation 6, one positive and one negative. If $S_{xy} > 0$, then the minimum of $SSE_p(b_1)$ is the positive root, and if $S_{xy} < 0$, the minimum is the negative root. This follows from the fact that there are two critical points for $\frac{\partial}{\partial b_1} SSE_p(b_1)$ one to the left of zero and one to the right of zero, and that the value at zero of $\frac{\partial}{\partial b_1} SSE_p(0) = -2S_{xy}$:

If $S_{xy} = 0$; the minimum of $SSE_p(b_1)$ is found from Equation 4 and (1) is S_{yy} with $b_1 = 0$ for $S_{yy} < S_{xx}$; (2) is S_{xx} with $b_1 = 1$ for $S_{xx} < S_{yy}$; and (3) is $S_{xx} = S_{yy}$ with any value of b_1 for $S_{xx} = S_{yy}$:

3 Example

For the data $f(0;0); (1;1); (1;0); (0;0)$ with $\bar{x} = 1; \bar{y} = 1; S_{xx} = 1; S_{yy} = 3; S_{xy} = 1$; $\bar{p} = 3$, the "best" straight line has $b_1 = 0.78078$ and $b_0 = 0.14039$.

4 Summary

We have investigated the fitted linear equation to data using as the criterion for the minimized sum of squares of the perpendicular errors.
