

NOWHERE WEAK DIFFERENTIABILITY OF THE PETTIS INTEGRAL

S.J. DILWORTH AND MARIA GIRARDI

Final Version: 31 October 1994

to appear: Quaestiones Mathematicae

ABSTRACT. For an arbitrary infinite-dimensional Banach space $\mathfrak{X}$, we construct examples of strongly-measurable $\mathfrak{X}$ -valued Pettis integrable functions whose indefinite Pettis integrals are nowhere weakly differentiable; thus, for these functions the Lebesgue Differentiation Theorem fails rather spectacularly. We also relate the degree of nondifferentiability of the indefinite Pettis integral to the cotype of $\mathfrak{X}$, from which it follows that our examples are reasonably sharp.

There are several generalizations of the space $L_1(\mathbf{R})$ of Lebesgue integrable functions taking values in the real numbers $\mathbf{R}$ (and defined on the usual Lebesgue measure space (Ω, Σ, μ) on $[0, 1]$) to a space of strongly-measurable “integrable” (suitably formulated) functions taking values in a Banach space $\mathfrak{X}$.

The most common generalization is the space $L_1(\mathfrak{X})$ of Bochner-Lebesgue integrable functions. Using the fact [P1, Theorem 1.1] that a strongly-measurable function is essentially separably-valued, one can easily extend Lebesgue’s Differentiation Theorem from $L_1(\mathbf{R})$ to $L_1(\mathfrak{X})$. Specifically [B; cf. DU, Theorem II.2.9], if $f \in L_1(\mathfrak{X})$, then

$$\lim_{h \rightarrow 0} \frac{1}{h} \int_t^{t+h} \|f(\omega) - f(t)\| d\mu(\omega) = 0$$

and so

$$\lim_{h \rightarrow 0} \frac{1}{h} \int_t^{t+h} f(\omega) d\mu(\omega) = f(t)$$

for almost all t in Ω .

Another generalization of $L_1(\mathbf{R})$ is the space $\mathcal{P}_1(\mathfrak{X})$ of strongly-measurable Pettis integrable functions. A function $f : \Omega \rightarrow \mathfrak{X}$ is Pettis integrable if for each $E \in \Sigma$ there is an element $x_E \in \mathfrak{X}$ satisfying

$$x^*(x_E) = \int_E x^* f d\mu$$

1991 *Mathematics Subject Classification.* 28A15, 46E40, 46G05.

for each x^* in the dual space $\mathfrak{X}^*$ of $\mathfrak{X}$. The element x_E is called the Pettis integral of f over E and we write

$$\mathcal{P} - \int_E f d\mu = x_E .$$

It is clear that $L_1(\mathfrak{X}) \subset \mathcal{P}_1(\mathfrak{X})$, while the reverse inclusion holds if and only if $\mathfrak{X}$ is finite dimensional (see e.g. [DG]).

If $f \in \mathcal{P}_1(\mathfrak{X})$, then for each $x^* \in \mathfrak{X}^*$ the function $x^*f \in L_1(\mathbf{R})$ and so there exists a set A (which depends on x^*) of full measure such that

$$\lim_{h \rightarrow 0} \frac{1}{h} \int_t^{t+h} x^*f(\omega) d\mu(\omega) = x^*f(t)$$

for each $t \in A$. In his paper [P1] introducing the Pettis integral, Pettis phrased this by saying that the Pettis integral of a function in $\mathcal{P}_1(\mathfrak{X})$ is *pseudo-differentiable*. He closed his paper by asking whether the Pettis integral of a function f in $\mathcal{P}_1(\mathfrak{X})$ enjoys the stronger property of being *a.e. weakly differentiable*; that is, does there necessarily exist a set A (*independent* of x^*) of full measure such that

$$\lim_{h \rightarrow 0} \frac{1}{h} \int_t^{t+h} x^*f(\omega) d\mu(\omega) = x^*f(t)$$

for each $t \in A$ and $x^* \in \mathfrak{X}^*$, or such that (which is the same thing of course)

$$\text{weak} - \lim_{h \rightarrow 0} \frac{1}{h} \mathcal{P} - \int_t^{t+h} f(\omega) d\mu(\omega) = f(t)$$

for each $t \in A$.

If $\mathfrak{X}$ is finite dimensional, then the Pettis integral of a function in $\mathcal{P}_1(\mathfrak{X})$ is a.e. weakly differentiable. R.S. Phillips [Ph] (for $\mathfrak{X} = \ell_2$) and M.E. Munroe [M] (for $\mathfrak{X} = C[0, 1]$) each constructed an example of a function in $\mathcal{P}_1(\mathfrak{X})$ whose Pettis integral is not a.e. weakly differentiable. G.E.F. Thomas [T, p. 131] conjectured that such a function in $\mathcal{P}_1(\mathfrak{X})$ exists for every infinite-dimensional Banach space $\mathfrak{X}$.

At the recent May 1993 Kent State University Functional Analysis Conference, Joe Diestel requested a further investigation into Pettis's question. Independently, V. Kadets [K] recently constructed, for each infinite-dimensional Banach space $\mathfrak{X}$, a function in $\mathcal{P}_1(\mathfrak{X})$ whose Pettis integral fails to be a.e. weakly differentiable; specifically, it fails to be weakly differentiable on a set of positive, but not full, measure.

The main theorem of this paper constructs, for each infinite-dimensional Banach space $\mathfrak{X}$, a function in $\mathcal{P}_1(\mathfrak{X})$ whose Pettis integral is *nowhere* weakly differentiable. This theorem also addresses the degree of nondifferentiability of the Pettis integral. Our second theorem shows, for *arbitrary* Banach spaces, that the functions which we construct are close to being optimal with respect to their degree of nondifferentiability. From these two theorems it follows (Corollaries 3 and 4) that the cotype of a space is closely tied to the degree of nondifferentiability of the Pettis integral.

Theorem 2 was shown to us by Nigel Kalton in answer to a question posed in a preliminary version of this paper. We are grateful to him for permission to include this result here.

To state our main result we introduce the collection Ψ of all increasing functions $\psi: [0, \infty) \rightarrow [0, \infty)$ satisfying the growth condition

$$\sum_{n=1}^{\infty} \psi(2^{-p_{n-1}}) \sqrt{2^{p_n}} < \infty, \quad (\dagger)$$

for some increasing sequence $\{p_n\}_{n=0}^{\infty}$ of integers. Examples of functions in Ψ are

$$\psi(s) = s^{\frac{1}{2}+\epsilon},$$

$$\psi(s) = s^{\frac{1}{2}} \left[\frac{1}{\log(1/s)} \right]^{1+\epsilon} \quad \text{and} \quad \psi(s) = s^{\frac{1}{2}} \left[\frac{1}{\log(1/s)} \right] \left[\frac{1}{\log \log(1/s)} \right]^{1+\epsilon}$$

for $p_n = n$ and any $\epsilon > 0$.

Theorem 1. *Let $\mathfrak{X}$ be an infinite-dimensional Banach space. For each $\psi \in \Psi$, there exists $f \in \mathcal{P}_1(\mathfrak{X})$ such that*

$$\left\| \mathcal{P} - \int_I f d\mu \right\|_{\mathfrak{X}} \geq \psi(\mu(I)) \quad (\ddagger)$$

for each interval I contained in $[0, 1]$.

Remark. Taking $\psi(t) = t^{\frac{3}{4}}$ gives a Pettis integrable function f such that for each $t \in \Omega$,

$$\lim_{h \rightarrow 0} \left\| \frac{1}{h} \mathcal{P} - \int_t^{t+h} f(\omega) d\mu(\omega) \right\|_{\mathfrak{X}} = \infty.$$

If the Pettis integral of this f were weakly differentiable at t , then the above limit would be finite.

Proof. Let $\{I_k^n : n = 0, 1, \dots; k = 1, \dots, 2^n\}$ be the dyadic intervals on $[0, 1]$, i.e.

$$I_k^n = \left[\frac{k-1}{2^n}, \frac{k}{2^n} \right).$$

Define inductively a collection $\{A_k^n : n = 0, 1, \dots; k = 1, \dots, 2^n\}$ of disjoint sets of strictly positive measure such that $A_k^n \subset I_k^n$ (e.g. appropriately chosen “fat Cantor” sets).

Fix $K > 1$. By a theorem of Mazur there is a basic sequence $\{x_n\}$ in $\mathfrak{X}$ with basis constant at most K . Take a blocking $\{F_n\}$ of the basis with each subspace F_n of large enough dimension to find (using the finite-dimensional version of Dvoretzky’s Theorem [D]) a 2^n -dimensional subspace E_n of F_n such that the Banach-Mazur distance between E_n and $\ell_2^{2^n}$ is less than 2. Note that $\{E_n\}$ forms a finite-dimensional decomposition. Next find operators $T_n: \ell_2^{2^n} \rightarrow E_n$ such that

$\|T_n\| \leq 2$ and $\|T_n^{-1}\| = 1$. Let $\{u_k^n : k = 1, \dots, 2^n\}$ be the standard unit vectors of $\ell_2^{2^n}$ and let $e_k^n \equiv T_n u_k^n$.

By the growth condition $(\dagger)$ on ψ , there is an increasing sequence $\{p_n\}_{n=0}^\infty$ of integers, with $p_0 = 0$, satisfying

$$\sum_{n=1}^{\infty} \psi(4 \cdot 2^{-p_{n-1}}) \sqrt{2^{p_n}} < \infty.$$

Define $f: [0, 1] \rightarrow \mathfrak{X}$ by

$$f(\omega) = \sum_{n=1}^{\infty} \sum_{k=1}^{2^n} c_n \frac{1_{A_k^n}(\omega)}{\mu(A_k^n)} e_k^n,$$

where

$$c_m = 2K [\psi(4 \cdot 2^{-p_{n-1}})] \cdot \delta_{m, p_n},$$

(here $\delta_{j,k}$ is the usual Kronecker delta symbol). Clearly, f is strongly measurable.

The Pettis integral of f is easily computable; namely,

$$\mathcal{P} - \int_E f d\mu = \sum_{n=1}^{\infty} \sum_{k=1}^{2^n} c_n \left(\int_E \frac{1_{A_k^n}}{\mu(A_k^n)} d\mu \right) e_k^n. \quad (*)$$

To see this, first note that the growth condition on ψ guarantees that the above series does indeed converge to an element of $\mathfrak{X}$, since

$$\begin{aligned} \left\| \sum_{n=p}^q \sum_{k=1}^{2^n} c_n \left(\int_E \frac{1_{A_k^n}}{\mu(A_k^n)} d\mu \right) e_k^n \right\|_{\mathfrak{X}} &= \left\| \sum_{n=p}^q \sum_{k=1}^{2^n} c_n \left(\int_E \frac{1_{A_k^n}}{\mu(A_k^n)} d\mu \right) T_n u_k^n \right\|_{\mathfrak{X}} \\ &\leq 2 \sum_{n=p}^q c_n \left\| \sum_{k=1}^{2^n} \left(\int_E \frac{1_{A_k^n}}{\mu(A_k^n)} d\mu \right) u_k^n \right\|_{\ell_2^{2^n}} \\ &= 2 \sum_{n=p}^q c_n \left[\sum_{k=1}^{2^n} \left| \int_E \frac{1_{A_k^n}}{\mu(A_k^n)} d\mu \right|^2 \right]^{\frac{1}{2}} \\ &\leq 2 \sum_{n=p}^q c_n \sqrt{2^n}, \end{aligned}$$

which approaches zero as $p, q \rightarrow \infty$. Now fix $E \in \Sigma$ and $x^* \in \mathfrak{X}^*$ and let $\epsilon_k^n = \text{sign}(x^* e_k^n)$. Then

$$\sum_{k=1}^{2^n} |x^* e_k^n| = \left| \sum_{k=1}^{2^n} \epsilon_k^n x^* T_n u_k^n \right| \leq \|T_n^*\| \|x^*\| \left\| \sum_{k=1}^{2^n} \epsilon_k^n u_k^n \right\|_{\ell_2^{2^n}} \leq 2 \|x^*\| (\sqrt{2^n}),$$

and so

$$\int_E \sum_{n=1}^{\infty} \left| \sum_{k=1}^{2^n} c_n \frac{1_{A_k^n}}{\mu(A_k^n)} x^*(e_k^n) \right| d\mu = \sum_{n=1}^{\infty} \int_E \left| \sum_{k=1}^{2^n} c_n \frac{1_{A_k^n}}{\mu(A_k^n)} x^*(e_k^n) \right| d\mu$$

$$\begin{aligned}
&\leq \sum_{n=1}^{\infty} \sum_{k=1}^{2^n} c_n \left(\int_E \frac{1_{A_k^n}}{\mu(A_k^n)} d\mu \right) |x^* e_k^n| \\
&\leq \sum_{n=1}^{\infty} \sum_{k=1}^{2^n} c_n |x^* e_k^n| \\
&\leq 2 \|x^*\| \sum_{n=1}^{\infty} c_n \left(\sqrt{2^n} \right) < \infty .
\end{aligned}$$

Thus we may interchange the integral and summation below to see that

$$\begin{aligned}
\int_E x^* f d\mu &= \int_E \sum_{n=1}^{\infty} \sum_{k=1}^{2^n} c_n \frac{1_{A_k^n}}{\mu(A_k^n)} x^*(e_k^n) d\mu \\
&= \sum_{n=1}^{\infty} \int_E \sum_{k=1}^{2^n} c_n \frac{1_{A_k^n}}{\mu(A_k^n)} x^*(e_k^n) d\mu = x^* \left(\sum_{n=1}^{\infty} \sum_{k=1}^{2^n} c_n \left(\int_E \frac{1_{A_k^n}}{\mu(A_k^n)} d\mu \right) e_k^n \right) , \blacksquare
\end{aligned}$$

as needed for (*).

Fix an interval $I \in \Sigma$. Find a dyadic interval $I_j^m \subset I$ such that $4 \mu(I_j^m) \geq \mu(I)$ and then find n such that $p_{n-1} \leq m < p_n$. Let P be the natural projection from $\sum \oplus E_j$ onto E_{p_n} . Since $\|P\| \leq 2K$,

$$\begin{aligned}
2K \left\| \mathcal{P} - \int_I f d\mu \right\|_{\mathfrak{X}} &\geq \left\| P \left(\mathcal{P} - \int_I f d\mu \right) \right\|_{\mathfrak{X}} \\
&= c_{p_n} \left\| \sum_{k=1}^{2^{p_n}} \left(\int_I \frac{1_{A_k^{p_n}}}{\mu(A_k^{p_n})} d\mu \right) e_k^{p_n} \right\|_{\mathfrak{X}} \\
&\geq c_{p_n} \left\| \sum_{k=1}^{2^{p_n}} \left(\int_I \frac{1_{A_k^{p_n}}}{\mu(A_k^{p_n})} d\mu \right) u_k^{p_n} \right\|_{\ell_2^{2^{p_n}}} \\
&= c_{p_n} \left[\sum_{k=1}^{2^{p_n}} \left| \int_I \frac{1_{A_k^{p_n}}}{\mu(A_k^{p_n})} d\mu \right|^2 \right]^{\frac{1}{2}} ,
\end{aligned}$$

and so since $A_k^{p_n} \subset I_k^{p_n} \subset I_j^m \subset I$ for some k ,

$$2K \left\| \mathcal{P} - \int_I f d\mu \right\|_{\mathfrak{X}} \geq c_{p_n} = 2K \psi(4 \cdot 2^{-p_{n-1}}) .$$

But ψ is increasing and $4 \cdot 2^{-p_{n-1}} \geq 4 \cdot 2^{-m} \geq \mu(I)$ and so

$$\left\| \mathcal{P} - \int_I f d\mu \right\|_{\mathfrak{X}} \geq \psi(\mu(I)) .$$

Thus f satisfies the statement of the theorem. ■

The functions in Ψ can be viewed as indicators of the degree of nondifferentiability (i.e. the poor “averaging behavior”) of the indefinite Pettis integral. For instance, taking

$$\psi(s) = s^{\frac{1}{2}} \left[\frac{1}{\log(1/s)} \right]^{1+\epsilon} ,$$

we deduce from Theorem 1 that there exists $f \in \mathcal{P}_1(\mathfrak{X})$ such that, not only do we have

$$\lim_{h \rightarrow 0} \left\| \frac{1}{h} \mathcal{P} - \int_t^{t+h} f(\omega) d\mu(\omega) \right\|_{\mathfrak{X}} = \infty ,$$

but even worse,

$$\lim_{h \rightarrow 0} h^{\frac{1}{2}} \cdot \left[\log \left(\frac{1}{h} \right) \right]^{1+\epsilon} \left\| \frac{1}{h} \mathcal{P} - \int_t^{t+h} f(\omega) d\mu(\omega) \right\|_{\mathfrak{X}} = \infty$$

for all $t \in \Omega$.

The next theorem shows that Theorem 1 comes close to describing the *worst* type of averaging behavior of the Pettis integral that can occur in an *arbitrary* infinite-dimensional Banach space. In particular, it shows that, for spaces on which the identity operator is $(2, 1)$ -summing (i.e., spaces with the Orlicz property), Theorem 1 fails to hold for the function $\psi(s) = s^{\frac{1}{2}}$. Thus, the growth condition $(\dagger)$ on $\psi \in \Psi$ can *not* be replaced by $\psi(s) = O(s^{\frac{1}{2}})$ as $s \rightarrow 0$. We do not know, however, whether it can be replaced by $\psi(s) = o(s^{\frac{1}{2}})$ as $s \rightarrow 0$.

Theorem 2. *If the identity operator on an infinite-dimensional Banach space $\mathfrak{X}$ is $(q, 1)$ -summing for some $2 \leq q < \infty$, then, for every $f \in \mathcal{P}_1(\mathfrak{X})$,*

$$\left\| \mathcal{P} - \int_t^{t+h} f d\mu \right\|_{\mathfrak{X}} = o\left(h^{\frac{1}{q}}\right)$$

as $h \rightarrow 0^+$ for μ -a.e. t .

The proof below, which uses a factorization theorem of Pisier [P], was pointed out to us by Nigel Kalton.

Proof. Fix $f \in \mathcal{P}_1(\mathfrak{X})$ for an infinite-dimensional Banach space $\mathfrak{X}$. Consider the operator $K: L_\infty \rightarrow \mathfrak{X}$ given by

$$K(g) = \mathcal{P} - \int_\Omega g(\omega) f(\omega) d\mu(\omega) .$$

We need to show that

$$\|K(1_{[0, t+h]}) - K(1_{[0, t]})\|_{\mathfrak{X}} = o\left(h^{\frac{1}{q}}\right)$$

as $h \rightarrow 0^+$ for μ -a.e. t . Fix $\epsilon > 0$.

Since K is compact and since the dual of L_∞ has the approximation property, there is [e.g. DU, Thm. VIII.3.6] a decomposition $K = K_1 + K_2$, with $K_i \in \mathcal{L}(L_\infty, \mathfrak{X})$, such that K_1 has finite rank and K_2 has norm at most ϵ^2 . It is enough to show that there is some constant A , which depends only on $\mathfrak{X}$ and q , such that for each i ,

$$\limsup_{h \rightarrow 0^+} h^{-\frac{1}{q}} \|K_i(1_{[0, t+h]}) - K_i(1_{[0, t]})\|_{\mathfrak{X}} \leq A \epsilon , \quad (\diamond)$$

on a set of μ -measure at least $1 - \epsilon^q$.

Towards this, consider [see e.g. R] the natural surjective isometry $\tau: L_\infty \rightarrow C(\Delta)$ for the appropriate extremally disconnected compact Hausdorff space Δ . Recall that τ takes an indicator function of a Borel set in $[0, 1]$ to an indicator function of a clopen set in Δ , say $\tau(1_A) = 1_{\widehat{A}}$ in such a way that if $A \subset B \subset \Omega$, then $\widehat{A} \subset \widehat{B} \subset \Delta$ and $\widehat{B \setminus A} = \widehat{B} \setminus \widehat{A}$. Let $\widehat{K}_i$ be the composite map:

$$\widehat{K}_i : C(\Delta) \xrightarrow{\tau^{-1}} L_\infty \xrightarrow{K_i} \mathfrak{X}.$$

First we deal with K_1 . We assume, without loss of generality, that K_1 is of rank one. So the mapping $\widehat{K}_1$ is of the form

$$\widehat{K}_1(\varphi) = \left[\int_{\Delta} \varphi d\lambda \right] x$$

for some norm one element x in $\mathfrak{X}$ and a finite regular signed Borel measure λ on Δ . Thus

$$\begin{aligned} \|K_1(1_{[0,t+h]}) - K_1(1_{[0,t]})\|_{\mathfrak{X}} &= \left\| \widehat{K}_1(1_{\widehat{[0,t+h]}}) - \widehat{K}_1(1_{\widehat{[0,t]}}) \right\|_{\mathfrak{X}} \\ &= \left| \lambda(\widehat{[0,t+h]}) - \lambda(\widehat{[0,t]}) \right| \\ &= |\alpha(t+h) - \alpha(t)|, \end{aligned}$$

where $\alpha: [0, 1] \rightarrow \mathbb{R}$ is given by $\alpha(t) = \lambda(\widehat{[0,t]})$. Since $\widehat{[0,t]} \subset \widehat{[0,t+h]}$ for positive h , the function α is of bounded variation and so is differentiable μ -almost everywhere. Thus, $\|K_1(1_{[0,t+h]}) - K_1(1_{[0,t]})\|_{\mathfrak{X}} = O(h)$ μ -a.e. and so $(\diamond)$ holds for any $q > 1$.

Now we deal with K_2 . Fix $2 \leq q < \infty$. If the identity operator on $\mathfrak{X}$ is $(q, 1)$ -summing, then [P, Cor. 2.7] there is a probability measure ν on the Borel sets of Δ such that the operator $\widehat{K}_2$ admits a factorization of the form

$$\begin{array}{ccc} C(\Delta) & \xrightarrow{\widehat{K}_2} & \mathfrak{X} \\ & \searrow J & \nearrow T \\ & L_{q,1}(\nu) & \end{array}$$

where J is the natural inclusion map and T is a bounded linear operator with operator norm at most $C\|\widehat{K}_2\| \leq C\epsilon^2$, where C depends only on $\mathfrak{X}$ and q . Here, $L_{q,1}(\nu)$ is the usual Lorentz space of all real-valued ν -measurable functions f on Δ for which the norm $\|f\|_{q,1}$ is finite, where

$$\|f\|_{q,1} = \int_0^\infty t^{\frac{1}{q}-1} f^*(t) dt$$

and f^* is the non-increasing rearrangement of $|f|$. As above

$$\begin{aligned} \|K_2(1_{[0,t+h]}) - K_2(1_{[0,t]})\|_{\mathfrak{X}} &= \|K_2(1_{(t,t+h]})\|_{\mathfrak{X}} \\ &= \|\widehat{K_2}(1_{\widehat{(t,t+h]}})\|_{\mathfrak{X}} \\ &\leq C\epsilon^2 \|J(1_{\widehat{(t,t+h]}})\|_{L_{q,1}(\nu)} . \end{aligned}$$

Since the non-increasing rearrangement of $J(1_{\widehat{(t,t+h]}})$ is just the indicator function of the set $[0, \nu(\widehat{(t,t+h]})]$, we have

$$\|J(1_{\widehat{(t,t+h]}})\|_{L_{q,1}(\nu)} = q \left[\nu(\widehat{(t,t+h]}) \right]^{\frac{1}{q}} ,$$

and so

$$h^{-\frac{1}{q}} \|K_2(1_{[0,t+h]}) - K_2(1_{[0,t]})\|_{\mathfrak{X}} \leq Cq\epsilon^2 \left[\frac{|\beta(t+h) - \beta(t)|}{h} \right]^{\frac{1}{q}} ,$$

where $\beta: [0, 1] \rightarrow \mathbb{R}$ is given by $\beta(t) = \nu(\widehat{[0,t]})$. The function β is increasing and hence differentiable μ -almost everywhere. Thus

$$\limsup_{h \rightarrow 0^+} h^{-\frac{1}{q}} \|K_2(1_{[0,t+h]}) - K_2(1_{[0,t]})\|_{\mathfrak{X}} \leq C q \epsilon^2 [\beta'(t)]^{\frac{1}{q}}$$

for μ -a.e. t . From $\int_0^1 \beta'(t) dt \leq \beta(1) - \beta(0) \leq 1$, it follows that $\mu[\beta'(t) \geq \epsilon^{-q}] \leq \epsilon^q$. Thus, on a set of measure at least $1 - \epsilon^q$,

$$\limsup_{h \rightarrow 0^+} h^{-\frac{1}{q}} \|K_2(1_{[0,t+h]}) - K_2(1_{[0,t]})\|_{\mathfrak{X}} \leq C q \epsilon ,$$

which implies $(\diamond)$ for K_2 . ■

Recall that the identity operator on a space with finite cotype q is $(q, 1)$ -summing. Indeed, cotype plays a major rôle in the unfolding drama. To see this, consider a space $\mathfrak{X}$ which contains a finite-dimensional decomposition $\sum \oplus E_n$ where the Banach-Mazur distance between E_n and $\ell_p^{2^n}$ is less than M for each n for some fixed $1 \leq p \leq \infty$ and $M > 1$. By modifying Mazur's construction [see e. g. LT] of a basic sequence and using the fact (a simple compactness argument suffices) that finite representability of ℓ_p is inherited by subspaces of finite codimension, it is possible to construct such a finite-dimensional decomposition in $\mathfrak{X}$ whenever ℓ_p is finitely representable in $\mathfrak{X}$. By the Maurey-Pisier Theorem [MP], ℓ_{q_0} is finitely representable in $\mathfrak{X}$ where $2 \leq q_0 \leq \infty$ and

$$q_0 = \inf \{q: \mathfrak{X} \text{ has cotype } q\} .$$

In the same spirit as in the proof of Theorem 1 (and with similar notation), for $1 \leq p \leq \infty$ let Ψ_p be the collection of all increasing functions $\psi: [0, \infty) \rightarrow [0, \infty)$ satisfying the growth condition

$$\sum_{n=1}^{\infty} \psi(2^{-p_{n-1}}) [2^{p_n}]^{\frac{1}{p}} < \infty \quad (\dagger_p)$$

for some increasing sequence $\{p_n\}_{n=0}^{\infty}$ of integers (following the convention that $1/\infty$ is 0). For $1 \leq p < \infty$, a typical function in Ψ_p is

$$\psi(s) = s^{\frac{1}{p} + \epsilon}$$

with $p_n = n$ and for any $\epsilon > 0$. For $p = \infty$, $(\dagger_p)$ reduces to the condition

$$\lim_{s \rightarrow 0^+} \psi(s) = 0.$$

Fix $\psi \in \Psi_p$ and find an increasing sequence $\{p_n\}_{n=0}^{\infty}$ of integers, with $p_0 = 0$, satisfying

$$\sum_{n=1}^{\infty} \psi(4 \cdot 2^{-p_{n-1}}) [2^{p_n}]^{\frac{1}{p}} < \infty$$

(again, $1/\infty$ is 0). Define $f: [0, 1] \rightarrow \mathfrak{X}$ by

$$f(\omega) = \sum_{n=1}^{\infty} \sum_{k=1}^{2^n} c_n \frac{1_{A_k^n}(\omega)}{\mu(A_k^n)} e_k^n,$$

where

$$c_m = 2K [\psi(4 \cdot 2^{-p_{n-1}})] \cdot \delta_{m, p_n},$$

where K is the finite-dimensional decomposition constant. Minor variations of the proof of Theorem 1 show that this function f satisfies

$$\left\| \mathcal{P} - \int_I f d\mu \right\|_{\mathfrak{X}} \geq \psi(\mu(I))$$

for each interval I contained in $[0, 1]$.

Theorems 1 and 2, along with the above observations, give the following corollaries.

Corollary 3. *Let $\mathfrak{X}$ be an infinite-dimensional Banach space with finite cotype and let $q_0 = \inf\{q: \mathfrak{X}_0 \text{ has cotype } q\}$. Then the following hold.*

(1) *If $p > q_0$, then for each $f \in \mathcal{P}_1(\mathfrak{X})$, we have*

$$\left\| \mathcal{P} - \int_t^{t+h} f d\mu \right\|_{\mathfrak{X}} = o\left(h^{\frac{1}{p}}\right)$$

as $h \rightarrow 0^+$ for μ -a.e. t .

(2) *If $p < q_0$, then there is an $f \in \mathcal{P}_1(\mathfrak{X})$ such that*

$$\left\| \mathcal{P} - \int_t^{t+h} f d\mu \right\|_{\mathfrak{X}} \geq h^{\frac{1}{p}}$$

for all $t \in [0, 1]$.

Corollary 4. *For an infinite-dimensional Banach space $\mathfrak{X}$, the following are equivalent.*

- (1) $\mathfrak{X}$ fails cotype.
- (2) For each $\psi \in \Psi_\infty$, there exists $f \in \mathcal{P}_1(\mathfrak{X})$ such that

$$\left\| \mathcal{P} - \int_I f d\mu \right\|_{\mathfrak{X}} \geq \psi(\mu(I))$$

for each interval I contained in $[0, 1]$.

Remark. Note that Corollary 4 proves the existence of a *reflexive* Banach space for which the Pettis integral has essentially no kind of differentiability property whatsoever.

Theorem 1 can be reformulated by considering the indefinite Pettis integral

$$g(t) = \mathcal{P} - \int_0^t f(\omega) d\mu(\omega) ,$$

and then expressing $(\ddagger)$ as

$$\|g(s) - g(t)\| \geq \psi(|s - t|) . \quad (\ddagger')$$

Corollary 4 shows that if g is the indefinite integral of a Pettis-integrable function taking values in a space failing cotype, then there are (essentially) no restrictions on ψ in $(\ddagger')$. Since $g(t)$ is always *continuous* [P1, Thm. 2.5], it is not unreasonable to inquire, in the case of an arbitrary infinite-dimensional Banach space, whether there are any restrictions on ψ which are attributable merely to the continuity of g as opposed to the additional fact that g is an indefinite Pettis integral. Our final result answers this question with a resounding no.

Theorem 5. *Let $\mathfrak{X}$ be an infinite-dimensional Banach space and let $\psi \in \Psi_\infty$. Then there exists a continuous function $f: \Omega \rightarrow \mathfrak{X}$ such that*

$$\|f(s) - f(t)\|_{\mathfrak{X}} \geq \psi(|s - t|)$$

for each s and t in Ω .

Remark. As Ralph Howard pointed out, Theorem 5 does not hold if $\mathfrak{X}$ is finite-dimensional. In fact, if f is a continuous function taking values in $\mathbb{R}^n$ and satisfying the lower estimate given above, then an easy Hausdorff dimension argument (see e.g. [Kah]) shows that the function ψ must satisfy $\liminf_{t \rightarrow 0} \psi(t)t^{\epsilon-1/n} < \infty$ for every $\epsilon > 0$.

Proof. Find an increasing sequence $\{p_n\}_{n=0}^\infty$ of integers with $p_0 = 0$ such that $\sum_n \psi(2^{-p_n})$ is finite and fix $K > 1$. Keeping with the notations and ideas of Theorem 1, find a finite-dimensional decomposition $\{E_n\}$ in $\mathfrak{X}$ and, to avoid excessive

superscripts, let $J_k^n = I_k^{p_n}$ and likewise $\tilde{e}_k^n = e_k^{p_n}$ and $\tilde{u}_k^n = u_k^{p_n}$ for each admissible n and k .

Consider the continuous piecewise-linear function

$$f_n(\omega) = \sum_{k=1}^{2^{p_n}} 2^{p_n} \left[\left(\frac{k}{2^{p_n}} - \omega \right) \tilde{e}_k^n + \left(\omega - \frac{k-1}{2^{p_n}} \right) \tilde{e}_{k+1}^n \right] 1_{J_k^n}(\omega).$$

If $\omega \in J_k^n$, then $f_n(\omega)$ is of the form $\alpha \tilde{e}_k^n + (1-\alpha) \tilde{e}_{k+1}^n$ for some $0 \leq \alpha \leq 1$. Thus the norm of $f_n(\omega)$ is at most 2 for each $\omega \in \Omega$. Define $f: \Omega \rightarrow \mathfrak{X}$ by

$$f(\omega) = \sum_{n=2}^{\infty} c_n f_n(\omega),$$

where

$$c_{n+2} = 2 K \psi(2^{-p_n}).$$

Since each f_n is uniformly continuous and

$$\left\| \sum_{n=p}^q c_n f_n(\omega) \right\| \leq 2 \sum_{n=p}^q c_n,$$

the choice of $\{p_n\}$ guarantees not only that $f(\omega)$ is indeed in $\mathfrak{X}$ for each $\omega \in \Omega$ but also that f is uniformly continuous.

Fix $s, t \in \Omega$. Find p_n such that $2^{-p_n} < |s - t| \leq 2^{-p_{n-1}}$. Since s and t are in neither the same nor adjacent intervals of the partition $\{J_k^{n+1}\}_k$ of Ω , for appropriate *distinct* integers $k-1, k, j$, and $j+1$,

$$\begin{aligned} f_{n+1}(s) &= \alpha \tilde{e}_{k-1}^{n+1} + (1-\alpha) \tilde{e}_k^{n+1} \\ f_{n+1}(t) &= \beta \tilde{e}_j^{n+1} + (1-\beta) \tilde{e}_{j+1}^{n+1} \end{aligned}$$

for some $0 \leq \alpha, \beta \leq 1$ and so

$$\begin{aligned} \|f_{n+1}(s) - f_{n+1}(t)\|_{\mathfrak{X}} &\geq \|\alpha \tilde{u}_{k-1}^{n+1} + (1-\alpha) \tilde{u}_k^{n+1} - \beta \tilde{u}_j^{n+1} - (1-\beta) \tilde{u}_{j+1}^{n+1}\|_{\ell_2} \\ &= \left[(\alpha)^2 + (1-\alpha)^2 + (\beta)^2 + (1-\beta)^2 \right]^{\frac{1}{2}} \\ &\geq 1. \end{aligned}$$

Let P be the natural projection from $\sum \oplus E_j$ onto $E_{p_{n+1}}$. Since ψ is increasing, we see that

$$\begin{aligned} 2 K \|f(s) - f(t)\|_{\mathfrak{X}} &\geq \|P(f(s) - f(t))\|_{\mathfrak{X}} \\ &= c_{n+1} \|(f_{n+1}(s) - f_{n+1}(t))\|_{\mathfrak{X}} \\ &\geq c_{n+1} \\ &= 2 K \psi(2^{-p_{n-1}}) \\ &\geq 2 K \psi(|s - t|). \end{aligned}$$

Thus f satisfies the statement of the theorem. ■

Remark. Theorem 5 really only uses the existence of a basic sequence inside $\mathfrak{X}$, while Theorem 1 makes full use of Dvoretzky's Theorem.

We close with a few observations. [DG, Ex. 3] constructs, for each fixed infinite-dimensional Banach space $\mathfrak{X}$, a strongly-measurable $\mathfrak{X}$ -valued function that is Pettis integrable but not Bochner-Lebesgue integrable; however, that function *is* Bochner-Lebesgue integrable over *any* interval not containing 0. Theorem 1 pushes this construction a bit further to give a Pettis integrable function that *is not* Bochner-Lebesgue integrable over *any* interval.

Consider the collection $K(\mu, \mathfrak{X})$ of the μ -continuous countably additive $\mathfrak{X}$ -valued vector measure with relatively compact range. If f is in $\mathcal{P}_1(\mathfrak{X})$, then the corresponding measure $\nu_f(E) = \mathcal{P} - \int_E f d\mu$ is in $K(\mu, \mathfrak{X})$ [cf. DU, Thm. VIII.1.5]. The measure $\nu_f(E)$ is of bounded semi-variation; furthermore, $\nu_f(E)$ is of bounded variation if and only if f is in $L_1(\mathfrak{X})$ [cf. DU, Thm. II.2.4, Cor. 2.5]. Theorem 1 (consider the measure ν_f corresponding to f as above) and [JK, Theorem 2] both construct, for each fixed infinite-dimensional Banach space $\mathfrak{X}$, a vector measure in $K(\mu, \mathfrak{X})$ that is of bounded semi-variation but of infinite variation on every interval. The measure in [JK, Theorem 2] cannot arise, however, as an indefinite Pettis integral, while the measure from Theorem 1 is (of course) precisely an indefinite Pettis integral.
