#### Abstract

C lassical billiards constitute an im portant class of dynam ical system s. They have not only been in used in $m$ athem aticaldisciplines such as ergodic theory, but their properties dem onstrate fundam ental physical phenom ena that can

be observed in laboratory settings. This docum ent provides instructions for a M atlab m odule that sim ulates classical billiard system s . It is intended to be used as both a research and teaching tool. At present, the program e ciently sim ulates tables that are constructed entirely from line segm ents and elliptical arcs. It functions less reliably for tables with $m$ ore com plex boundary com ponents. The program and docum entation can be downloaded from http://www m ath.gatech.edu/ mason/papers/.

## 1 Introduction

In classical billiard system $s$, a point particle is con ned to a region in conguration space and collides w ith the boundary of the region such that the angle of incidence equals the angle of re ection. A s the velocity of the point particle is constant, billiard system s are $H$ am iltonian. ${ }^{4}$ D epending on the geom etry of a particular billiard table, there exist integrable and/or chaotic regions in phase space.

## 2 O verview of the P rogram

T he billiard sim ulation tool is a M atlab m odule w ith a G raphicalU ser Interface (G U I). It is run by executing 'billiards' in $M$ atlab's com $m$ and $w$ indow while the les are in M atlab's path. U sers specify billiard tables by selecting from eight di erent preprogram $m$ ed tables or creating their ow $n$. T he initial position and velocity (angle) of a tra jectory are subsequently typed or speci ed by clicking on a point in phase space. The desired num ber of iterations
is also entered. A fter the program sim ulates the resulting collisions, the data can be exported and analyzed. E ach tim e the point particle collides w ith the boundary, the position and direction (i.e., $m$ om entum ) are calculated. The position is described by an arclength param etrization of the table, and the direction is described by an angle $m$ easured $w$ ith respect to the horizontal angle.

The sym bolic $m$ ath toolbox, which contains the $M$ aple kemel, is required in order to run the billiard program . T his toolbox is used to take the derivative of the table boundaries w th the di com m and. This G U I billiard sim ulator works w ith M atlab releases 12 and 13.

## 3 Bunim ovich M ushroom

### 3.1 Entering the table

In order to illustrate how to use the billiard sim ulator, we will dem onstrate an exam ple step-by-step. The table we use is shaped like a mushroom; it consists of a sem icircular region w ith a rectangular region extending from the base of the sem icircle. M ushroom billiards are scienti cally interesting, as they constitute a generalization of the stadium billiard with a divided phase space in which som e regions are chaotic and others are integrable. The com pletely integrable sem icircle and the com pletely chaotic stadium billiards are $m$ ushroom $s w$ ith lim iting values for the $w$ idth of the stem .

O ne opens the billiard sim ulator by executing 'billiards' in the $M$ atlab com $m$ and $w$ indow when the folder containing the program's les are in the path. Because the $m$ ushroom is a preprogram $m$ ed table, it is selected from
the pop-up m enu w ith 'P ick a table' as the default selection. A pull-down bar, four labels, and edit boxes w ill appear. The pull-down bar is used to select either a circular or ellipticalm ushroom. In this exam ple, we w ill w ork w ith a circularm ushroom. $N$ um bers are entered into the edit boxes to select the desired dim ensions of the m ushroom. The 'radius' refers to the radius of the sem icircle, and the 'height' and 'w idth' of the stem refer to the dim ensions of the rectangular region of the mushroom . The ratio of left to right sides enables the creation of desym $m$ etrized $m$ ushroom $s$ and should be set to 1 for sym $m$ etric $m$ ushroom $s$. A fter the four param eters have been entered, a preview of the mushroom will be displayed.

### 3.2 Entering the in itial conditions

O nœe the table is created, one speci es the initial conditions and the num ber of iterations. Initial conditions can be entered in two $m$ anners. $C$ lick on the $x$ and $y$ button. The $x$ and $y$ locations give the initial position of the point particle. The angle speci es the intitial direction of the point particle and is $m$ easured in radians. The 'num ber of iterations' speci es how $m$ any collisions the sim ulator will calculate. T he 'run' button begins the sim ulation. Figure 1 show s a screen shot of the program prior to running the sim ulation.

### 3.3 Running the sim ulation

W hen the 'run' button is pressed, M atlab begins the sim ulation. The program displays the num ber of iterations com pleted out of the total num ber requested. The 'stop' button discontinues the sim ulation. The m odule will not respond to user interactions until the current iteration is com pleted.

Figure 1: Entering a m ushroom table and initial conditions.

### 3.4 A nalysis

$T$ he analysis $w$ indow displayed in $F$ igure 2 w ill appear after the sim ulation is complete. T he raw data from the simulation can be exported $w$ ith the raw data box on the left. This option enables the user to further analyze the calculated data. T he desired type of data should be selected from the list box on the left and can either be displayed in the com $m$ and $w$ indow or saved by choosing the appropriate radio button. T he 'O K 'button on the left exports the data. T he 'P ieces hit' option gives the sym bolic dynam ics of the in itial conditions; the pieces are assigned num bers based on the order of the param etric functions in the piecew ise de nition of the table.

Speci c plots can be generated w ith the list box on the right. T he con $9-$ uration space (see Figure 3) displays the table and the paths of any tra jecto-

Figure 2: A nalysis w indow for B illiards.
ries. T he phase space plots display P oincare sections of the billiard system . T he variable $t$ gives the location on the boundary at whidh the point particle collides; it is de ned by the param etric equations describing the table. T he incident angle gives the direction of the point particle after the collision and is $m$ easured relative to the norm al of the boundary at the collision point. T he horizontal angle gives the direction of the point particle after the collision w ith respect to the horizontal. Figure 4 show s the phase space oftvs $\sin ($ ) for the B unim ovich m ushroom. T he incident angles, horizontal angles, distance betw een bounces, and frequency ofpieces hit options display histogram s of the appropriate data, although it $m$ ay be desirable to export this data in order to perform additional analysis. T he histogram s are generated using the $M$ atlab function hist. $T$ he plots are displayed by pressing the 'OK ' button on the right side. T he billiard table and data can be saved and

Figure 3: C on guration space for them ushroom w ith an integrable trajectory depicted.
opened later using the lemenu.

### 3.5 N ew in itial conditions

The options in the bottom right of the window enable the user to generate additional data. The ' N ew Table' button clears all data and resets the program so that a new table can be entered. The N ew Intial Conditions' button retains all the calculated data, and the user can enter new initial conditions for the current table. M ore iterations are calculated for the sam e initial conditions by entering the desired num ber of additional iterations and pressing the M ore Iterations' button. T he program will continue where the last sim ulation stopped.

Figure 4: Phase space for the $m$ ushroom with an integrable trajectory depicted.

To continue the m ushroom exam ple, click on the N ew InitialC onditions' button. This time, we will enter the initial conditions using the arclength variable $t$. $W$ ith this $m$ ethod, one speci es a location on the table boundary w ith $t$ and a direction by specifying the incident angle of the tra jectory to the table. O ne $m$ ay either type in values for $t$ and the incident angle or select them from phase space. C licking on the 'Select from phase space' button w ill open a plot of phase space w ith data from allprevious initialconditions. U se the cross hairs to select an initial condition, and the corresponding $\infty$ ordinates are entered into the billiard sim ulator. If m ore accuracy is desired than is possible w ith the cross hairs, the zoom tool can be used to m agnify a particular portion of phase space. In this case, the coordinates from phase space m ust be typed into the program. To continue with this guided

Figure 5: Entering new initial conditions for the m ushroom .
exam ple, enter the initial conditions show n in F igure 5 .
A fter M atlab's com putations are done, the analysis window is again displayed. The resulting con guration and phase space plots are depicted in Figure 6. N ote that the rst set of initial conditions speci es a tra jectory that rem ains in the sem icircular region of the $m$ ushroom. T he set of all such tra jectories com prise an integrable region of phase space. On the other hand, the second set of initial conditions corresponds to a tra jectory that collides $w$ th the stem of the mushroom. These trajectories form a chaotic region of phase space. This exam ple shows how circular mushroom sexhibit a divided phase space that contains exactly one integrable region and exactly one chaotic region. ${ }^{1}$

Figure 6: C on guration space and phase space of a m ushroom billiard with two initial conditions depicted.

## 4 C om posite B illiard Tables

Composite billiard tables can be constructed by combining multiple sim ple billiard tables. Such com posite tables are necessary, for exam ple, when considering any table in which the boundary cannot be described by one continuous curve. (O ne com posite table, the Sinaibilliard, is preprogram $m$ ed.) O ne can im plem ent such tables w ith the 'A dd another table' button. To illustrate this, consider a com posite table consisting of an o -center circle inside an ellipse. First, the ellipse is selected from the 'P idk a table' pop-up $m$ enu. O ne enters param eters for the lengths of the horizontal and vertical axes. The 'A dd another table' button appears once both param eters are entered. Figure 7 displays the entered ellipse and the 'A dd another table'
button.

F igure 7: Entered param eters and preview of the ellipse.

The second com ponent of the com posite table can now be added. It is entered as norm alexcept that the previous com ponent rem ains a part of the table. In this exam ple, the circle option is selected from the pop-up m enu. The radius is entered as norm al. Now we need to m ove the circle so that the circle and the ellipse are not concentric. This is accom plished by editing the x and y coordinates under the center label. The preview is redraw n once the center of the current com ponent of the table has been $m$ oved to the new coordinates. Figure 8 show s the com pleted com posite table. T he num bering of the pieces and value of the variable $t$ for each subsequent com ponent of a com posite table continue where the previous com ponents left o .

Figure 8: C om pleted com posite table.

## 5 B illiard Table M aker

The strength of the billiard program lies in its generality, as it can sim ulate any classical planar billiard system. If one desires to analyze a table that is not preprogram $m$ ed, it can be designed using the B illiard Table M aker, which is opened by selecting 'C ustom table...' from the 'P idk a table' pull-down bar.

A s an exam ple, we w ill use the Billiard Table M aker to create a stadium billiard $m$ odi ed so that one of the straight segm ents is replaced by a sinusoidal function. W e start by creating a vertical line that $w$ ill form one side of the m odi ed stadium . To do this, clidk the 'Line' button. At this point, note that the mouse controls a pair of cross hairs that are used to select the starting and ending points of the line. For this exam ple, $(1 ; 2)$ and then
(1; 2) were selected. The program then draw s the line segm ent connecting these two points, as show $n$ in $F$ igure 9.

Figure 9: Line segm ent draw $n$ w th the $B$ illiard $T$ able $M$ aker.

We now wish to add a sem icircular region to form the bottom of the m odi ed stadium . Because we are adding a new piece w here the previous one ended, we want to use the 'C ontinue from last endpoint' feature on the left, which is the default setting. The 'Start at new endpoint' feature allow s one to construct tables that cannot be described with a single boundary curve. C lick on the 'Sem icircle' button. U sing the cross hairs, select ( $1 ; 2$ ) for the endpoint of the sem icircle and select any point above the line connecting the endpoints of the sem icircle to designate the inside of the sem icircle. T he resultant table is shown in F igure 10.

The next piece to add is a sinusoid for the left side of the $m$ odi ed stadium . A $s$ this is not a basic piece (line segm ent, quarter circle, sem icircle,

Figure 10: Sem icircle added to the endpoint of the previous piece.
or quarter ellipse), we m ust use the 'P aram etric...' push button. W ith this feature, one can add a piece by entering param etric equations of a curve. C licking on the push button brings up a window in which one enters $x(t)$, $y(t)$, and lower and upper bounds for $t$. $N$ ote that the default value for the lower bound is 0 , but this can be changed to any desired value. T he para$m$ etric equations for this exam ple and the resultant table are show $n$ in $F$ igure 11. The vertical axis of the $w$ indow has autom atically been scaled to $m$ ake sure the last piece is show $n$ in the grid. The axis can be edited $m$ anually by changing the $m$ inim $u m$ and $m$ axim values for $x$ and $y$ displayed on the left.

W e will now add an upper sem icircle to com plete the billiard table. To ilhustrate this feature, select the radio button 'T ype' under 'C oordinate E ntry M ethod.' This enables the user to accurately specify the coordinates of

F igure 11: P aram etric equations for the sinusoidal piece of the table and the resultant table.
the input points. Because the program rounds input points, the altemate $m$ ethod of clicking on the graph to select points only allow s points with integer coordinates to be selected. C lidking on the 'Sem icircle' push button brings up a window to enter coordinates. The entered coordinates and the nal billiard table are shown in $F$ igure 12. Q uarter ellipses in which the $m$ a jor and $m$ inor axes are parallel to the coordinate axes can also be created in a sim ilar $m$ anner by using the ' Q uarter Ellipse' button. O ne can either save the table now or retum to B illiards by clicking on the 'D one' button.

## 6 M ovies

O ne can create $m$ ovies to view an anim ation of generated billiard data. C ontrols for doing this are located at the bottom left of the analysis window . M ovies of con guration and/or phase space can be created by checking the

Figure 12: Entering coordinate points for sem icircle and com pleted billiard table.
appropriate boxes. Such $m$ ovies show one fram $e$ for each iteration and highlight the $m$ ost recently draw $n$ titeration. The fram es rate can be modi ed using the options menu. M ovies can only be created for the m ost recent initial condition and should be used only w ith a sm all num ber of terations due to mem ory lim itations. By selecting the appropriate radio button, the m ovie can be view ed in M atlab, saved as a M atlab m ovie, or saved as an avi le. For every option, each fram e of the anim ation is rst displayed on the screen. A fter all fram es have been rendered, the $m$ ovie $w$ ill be displayed or a save dialog box will appear depending on which radio button is selected.

## 7 D escription of T ables

The program stores billiard tables in a cellarray. For exam ple, Table[1 show s the table created in the previous section. A table is given by a piecew ise fiunc-
tion; each row describes a piece of the table. The rst and second colum ns are param etric equations for the x and y coordinates for each piece of the table $[x(t)$ and $y(t)]$. The equations are stored as $M$ atlab inline functions. The third and fourth colum ns give the bounds for $t$, which is used as the dum $m y$ variable for the param etrization. The functions $x(t)$ and $y(t)$ have been scaled to the appropriate expressions so that $t$ also represents the arc length from the starting point of the billiard table to the current point for a given connected com ponent of the billiard. For com posite tables, the value of $t$ for each com ponent starts at the same value of $t$ used at the end of the previous com ponent. The nalcolum $n$ of the table contains a ag that determ ines the nature of the piece. For line segm ents, 1 is stored in the nal colum $n$; for circular or elliptical arcs, 2 is stored in the nal colum $n$; if the piece is neither a line segm ent nor one of arcs speci ed above, then 0 is stored in the nal column. N ote, how ever, that if a piece is entered by typing in param etric equations, then the nalcolum $n$ is autom atically 0 regardless of the actual identity of the piece. C ircular and elliptical arcs that sweep out arbitrary angles $m$ ust be entered param etrically. The three di erent types of pieces are treated di erently during the sim ulation.
$P$ aram etric equations that constitute exterior boundaries to the table $m$ ust be traced in the clockw ise direction, whereas interior boundaries $m$ ust be traced in the counterclockw ise sense. For exam ple, the exterior square of the Sinaibilliard is oriented clockw ise, and the interior circle is oriented counterclockw ise. If the w rong direction is used to param eterize the boundary, specifying initial conditions using $t$ and the incident angle $w$ ill not w ork properly, as the incident angle will be on the w rong side of the curve.

| $x(t)$ | $y(t)$ | lower bound | upper bound | ag |
| :---: | :---: | :---: | :---: | :---: |
| 1 | 2 t | 0 | 4 | 1 |

Table 2: D ata for pentagon sim ulation.

## 8 D escription of $R$ aw $D$ ata

The billiard sim ulator calculates and stores inform ation describing each collision of the point particle w th the boundary. For exam ple, consider the sim ulation of a regular pentagon $w$ th side length 1 and initial location ( $0 ; 0$ ) w th an angle of 2 . Figure 13 show s the con guration space for this sim ulation; raw data is presented in Table 2 .

Each collision w th the table is described by a row of data. T he location of the point on the boundary that the particle hits is given in the rst colum $n$ as a value oft. This value can be converted into $x$ and $y$ coordinates by eval-

Figure 13: C on guration space of pentagon sim ulation.
uating the appropriate expressions in the table $m$ atrix. The second colum $n$ gives the horizontal angle 2 [ ; ], which is a m easure of the angle of a vector in the direction the particle travels after colliding with the boundary. The quantities $t$ and give, respectively, the position and direction of the point particle im $m$ ediately after its collision $w$ th the boundary. The third Colum $n$ contains the tangential angle $2[\quad=2 ;=2]$, which is the angle between the norm al to the position of the boundary the particle hits and the exiting path taken by the particle. Negative angles indicate the exiting path is clockw ise from the nom al, whereas positive angles indicate that the exiting path is counterclockw ise from the nom al. $T$ he fourth colum $n$ gives the piece the particle hits. The sequence of such pieces encodes a sym bolic dynam ics for the given tra jectory. Sets of data for each initial condition are stored by the program in a œell array called 'data.'

## 9 C alculation of iterations

The program runs iteratively in its sim ulation of classical billiards. G iven the position and direction of the previous collision, the program calculates the position and direction of the point particle after its subsequent collision w ith the boundary. To nd the location of the next collision, the program searches for an intersection betw een the line that describes the path of the point particle and each of the table's param etric pieces. Given all such intersections, the point $w$ ith the $m$ inim um distance traveled is the next point of intersection. To nd the direction in which the point particle travels follow ing the collision, the nom alangle to the boundary is com puted from the derivatives of the equations of the table at the point of intersection. A ddition and subtraction of angles is used to calculate the exit angle from the norm al angle and the entrance angle:

$$
\begin{align*}
& \mathrm{n}=2 \arctan \frac{d y}{d t} \frac{d x}{d t} t_{n} \quad n 1 ; \\
& { }_{n}=\arctan \frac{d y}{d t} \frac{d x}{d t} \quad t_{n} \quad n_{1}+=2 ; \tag{1}
\end{align*}
$$

where $n$ represents the angle $w$ ith respect to the horizontal of the $n$th iteration, $n$ represents the incident angle of the $n$th iteration, $y(t)$ and $x(t)$ are the param etric equations of the boundary, and $t_{n}$ is the value of $t$ that gives the location of the nth intersection w ith the boundary. In M atlab, equation (1) is im plem ented using the arctan2' function to ensure that one obtains the correct quadrant for the angle. A dditionally, note that $n i$ does not appear in the right-hand-side of (1), as this angle is used only for phase space plots and is not involved in the calculation of angles in subsequent iterations.

### 9.1 C orners

Special consideration $m$ ust be em ployed if the point particle collides $w$ ith a comer of the billiard table, as such points corresp ond to singular points of the billiard (P oincare) m ap obtained from exam ining only the collisions (and not the straight paths between them ) of the vector eld describing the billiard system . ${ }^{4}$ This occurs when the point particle's path reaches a point where tw o pieces of the table join abruptly (w ith discontinuous rst derivative with respect to arc length). In the present num erical im plem entation, whenever the point particle collides w ith the boundary at a point where $t$ is within $10^{8}$ of the beginning or end of a piece, it is considered to have hit a comer. In order to num erically com pute the angle with which the point particle leaves the collision, the tangential angles of the tw o pieces of the table are averaged. The point particle subsequently bounces o a boundary oriented at this angle as if the collision were nom al. (W hen studying billiard system s using this program, one needs to be carefiul if a tra jectory hits the boundary too close to a comer.)

## 10 P recision

Errors due to round-o can grow quidkly w th our billiard simulations, as frequently occurs for repetitive num erical approxim ations. The rate that the errors com pound depends fiundam entally on the geom etry of the billiard table. For certain billiard tables, the error is negligible for a very large num ber of iterations. For others, this is not the case.

Two exam ples are presented to dem onstrate how the accuracy of the
sim ulation depends on the particular table. In the circular billiard w ith unit radius, we exam ined the tra jectory starting at (:5;0) w ith an initialhorizontal direction. T he maxim um error in the incident angle after 10;000 iterations was only 1:1213 $10^{13}$.

C onsider, how ever, a billiard table consisting of tw o circles of unit radius w ith respective centers at $(1: 5 ; 0)$ and ( $1: 5 ; 0)$. The initial conditions were set to the origin $w$ ith a horizontal angle. The point particle was then calculated to escape the tw o circles due to round-o error after 10 iterations. This extrem e exam ple of a num erically unstable periodic orbit dem onstrates that one $m$ ust be cautious when using the program .

## 11 K nown Errors

The current program is not yet reliable for tables that contain pieces that are not line segm ents or elliptical arcs. The program will work properly until it fails to nd where a trajectory intersects a com plex curve. This problem is due to an inability of the program to reliably nd a zero of a given function on a given interval.

## 12 A dditional Features to be Im plem ented

A useful analytical tool would entail the creation of a $M$ arkov partition of phase space. For each point in phase space, the piece against which the point particle will collide on the next iteration will be determ ined. This w ill create a $M$ arkov partition by dividing phase space so that every point in
the sam e region $w$ ill collide $w$ ith the sam e piece on the next iteration. This w ill be visually im plem ented by coloring phase space. The partition will allow one to easily view the sym bolic dynam ics for the rst several iterations associated w ith any initial condition.

O ne can im plem ent a M arkov partition by nding the criticalangles that cause the next collision of the point particle to collide w ith a di erent piece. The vertical segm ent of phase space that corresponds to this location can then be colored based on which piece w ill next be hit. This process w ill then continue for the entire boundary of the billiard table; all of these vertical segm ents are then joined to form the $M$ arkov partition.

If the regions of phase space described above can be found, the $M$ arkov partition can be used to speed up the billiard sim ulator considerably. For each iteration, the program currently m ust check all pieces of the table to nd the proper intersection. This process is very costly, as a oating point root nder is used each time to nd all possible intersections between the point particle's path and the table. W ith the im plem entation of a $M$ arkov partition, the program will be able to determ ine which segm ent the particle subsequently hits instead of searching for the right piece. The progrom will no longer spend time nding irrelevant roots, which will im prove the speed and e ciency of the billiard sim ulator substantially.

Future versions of the program can also include com putations of im portant quantities such as Lyapunov exponents. In the long run, we would ultim ately like to expand the program to sim ulate quantum billiards as well as classical ones. P henom ena such as scarring would then be especially easy to study.

## 13 C onclusions

W e created a G U I M atlab m odule that sim ulates classical billiards. It provides a usefiul research and teaching tool for scientists interested in these dynam ical system $s$. This m odule's sim ulations can be used not only to produce accurate phase space and Poincare section plots for scienti c publications but also to gain considerable $m$ athem atical and physical insight.

## A cknow ledgem ents

W e gratefilly acknow ledge Leonid Bunim ovich for useful scienti c discussions during this research pro ject and Peter M ucha for providing assistance w ith technical M atlab issues. The REU sum m er program at the School of $M$ athem atics and the $P$ resident's U ndergraduate $R$ esearch $A$ ward (PURA) at the Georgia Institute of Technology provided nancial assistance.
