# Trigonometric Lax matrix for the Kowalevski gyrostat on so(4) 

I.V. Komarov, A.V. Tsiganov<br>St.Petersburg State University, St.Petersburg, Russia

#### Abstract

We present trigonometric Lax matrix and classical $r$-matrix for the Kowalevski gyrostat on so(4) algebra by using auxiliary matrix algebras $s o(3,2)$ or $s p(4)$.

In this note we consider the Kowalevski gyrostat with the Hamiltonian

$$
\begin{equation*}
H=J_{1}^{2}+J_{2}^{2}+2 J_{3}^{2}+2 \rho J_{3}+2 y_{1}, \quad \rho \in \mathbb{R} \tag{1}
\end{equation*}
$$

on a generic orbit of the so(4) Lie algebra with the Poisson brackets

$$
\begin{equation*}
\left\{J_{i}, J_{j}\right\}=\varepsilon_{i j k} J_{k}, \quad\left\{J_{i}, y_{j}\right\}=\varepsilon_{i j k} y_{k}, \quad\left\{y_{i}, y_{j}\right\}=\varkappa^{2} \varepsilon_{i j k} J_{k}, \tag{2}
\end{equation*}
$$

where $\varepsilon_{i j k}$ is the totally skew-symmetric tensor and $\varkappa \in \mathbb{C}$. These brackets are invariant with respect to transformation $y_{i} \rightarrow a y_{i}$ and $\varkappa \rightarrow a \varkappa$, which allows to include scaling parameter $a$ into the Hamiltonian.

Because physical quantities $y, J$ in (11) should be real, $\varkappa^{2}$ must be real too and algebra (2) is reduced to its two real forms so $(4, \mathbb{R})$ or $s o(3,1, \mathbb{R})$ for positive and negative $\varkappa^{2}$ respectfully and to $e(3)$ for $\varkappa=0$.

At $\varkappa=0$ the Lax matrix for the Kowalevski gyrostat on $e(3)$ algebra was found in [1]

$$
L_{0}(\lambda)=\left(\begin{array}{rrrrr}
0 & J_{3} & -J_{2} & \lambda-\frac{y_{1}}{\lambda} & 0  \tag{3}\\
-J_{3} & 0 & J_{1} & -\frac{y_{2}}{\lambda} & \lambda \\
J_{2} & -J_{1} & 0 & -\frac{y_{3}}{\lambda} & 0 \\
\lambda-\frac{y_{1}}{\lambda} & -\frac{y_{2}}{\lambda} & -\frac{y_{3}}{\lambda} & 0 & -J_{3}-\rho \\
0 & \lambda & 0 & J_{3}+\rho & 0
\end{array}\right) .
$$

In order to construct this matrix in framework of a general group-theoretical approach the auxiliary algebra $\mathfrak{g}=s o(3,2)$ is taken.

At $\varkappa \neq 0$ the Lax matrix for the Kowalevski gyrostat on so(4) is deformation of the matrix $L_{0}(\lambda)$ [2]

$$
\begin{equation*}
L(\lambda)=Y \cdot L_{0}(\lambda), \quad Y=\operatorname{diag}\left(1,1,1, \frac{\lambda^{2}}{\lambda^{2}-\varkappa^{2}}, 1\right) \tag{4}
\end{equation*}
$$

The corresponding classical $r$-matrix has been constructed in [3]. The algebraic nature of the matrix $L(\lambda)$ (4) was mysterious, because diagonal matrix $Y$ does not belong to the auxiliary $s o(3,2)$ algebra.

In this note we present simple trigonometric Lax matrix and the corresponding trigonometric $r$-matrix on $s o(3,2)$ or $s p(4)$ algebras. Similar to [1] in order to get the Lax matrices and the $r$-matrix for the Kowalewski gyrostat on so(4) we use the the auxiliary Lie algebra $\mathfrak{g}=s o(3,2)$ in fundamental representation.

Let us describe this auxiliary space by using one antisymmetric matrix and three symmetric matrices

$$
S_{4}=\left(\begin{array}{ccccc}
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & -1 \\
0 & 0 & 0 & 1 & 0
\end{array}\right), \quad Z_{1}=\left(\begin{array}{ccccc}
0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0
\end{array}\right), \quad Z_{2}=\left(\begin{array}{ccccc}
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0
\end{array}\right) \quad Z_{3}=\left(\begin{array}{ccccc}
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0
\end{array}\right),
$$

which are the generators of the $s o(3,2)$ algebra. There are three other symmetric matrices

$$
H_{i}=\left[Z_{i}, S_{4}\right] \equiv Z_{i} S_{4}-S_{4} Z_{i}, \quad i=1,2,3
$$

and three other antisymmetric matrices

$$
S_{1}=\left[Z_{2}, Z_{3}\right], \quad S_{2}=\left[Z_{3}, Z_{1}\right], \quad S_{3}=\left[Z_{1}, Z_{2}\right] .
$$

Four matrices $S_{k}$ form maximal compact subalgebra $\mathfrak{f}=s o(3) \oplus s o(2)$ of $s o(3,2)$ , whereas six matrices $Z_{i}$ and $H_{i}$ belong to the complimentary subspace $\mathfrak{p}$ in the Cartan decomposition $\mathfrak{g}=\mathfrak{f}+\mathfrak{p}$. The corresponding Cartan involution is given by $\sigma: \quad X=-X^{T}$, where $X \in \operatorname{so}(3,2)$.

After similarity transformation $L(\lambda) \rightarrow Y^{-1 / 2} L(\lambda) Y^{1 / 2}$ of the $\operatorname{Lax} L(\lambda)$ (4) and change of the spectral parameter $\lambda=\varkappa / \sin \phi$ one gets a trigonometric Lax matrix on the auxiliary so $(3,2)$ algebra

$$
\begin{equation*}
L=\frac{\varkappa}{\sin \phi}\left(Z_{1}+\cos \phi H_{2}\right)+\sum_{i=1}^{3}\left(\cos \phi J_{i} S_{i}-\varkappa^{-1} \sin \phi y_{i} Z_{i}\right)+\left(J_{3}+\rho\right) S_{4} \tag{5}
\end{equation*}
$$

or

$$
L=\left(\begin{array}{rrrrr}
0 & \cos \phi J_{3} & -\cos \phi J_{2} & \frac{\varkappa}{\sin \phi}-\frac{\sin \phi}{\varkappa} y_{1} & 0  \tag{6}\\
-\cos \phi J_{3} & 0 & \cos \phi J_{1} & -\frac{\sin \phi}{\varkappa} y_{2} & \frac{\varkappa \cos \phi}{\sin \phi} \\
\cos \phi J_{2} & -\cos \phi J_{1} & 0 & -\frac{\sin \phi}{\varkappa} y_{3} & 0 \\
\frac{\varkappa}{\sin \phi}-\frac{\sin \phi}{\varkappa} y_{1} & -\frac{\sin \phi}{\varkappa} y_{2} & -\frac{\sin \phi}{\varkappa} y_{3} & 0 & -J_{3}-\rho \\
0 & \frac{\varkappa \cos \phi}{\sin \phi} & 0 & J_{3}+\rho & 0
\end{array}\right) .
$$

In order to consider the real forms so $(4, \mathbb{R})$ or $s o(3,1, \mathbb{R})$ we have to use trigonometric or hyperbolic functions for positive and negative $\varkappa^{2}$, respectively.

If we put $\phi=\varkappa \lambda^{-1}$ and take the limit $\varkappa \rightarrow 0$ one gets known rational Lax matrix $L_{0}(\lambda)$ (3) for the Kowalevski gyrostat on $e(3)$ [1]

$$
L_{0}=\lambda\left(Z_{1}+H_{2}\right)+\sum_{i=1}^{3}\left(J_{i} S_{i}-\lambda^{-1} x_{i} Z_{i}\right)+\left(J_{3}+\rho\right) S_{4} .
$$

The Lax matrices $L(\phi)$ and $L_{0}(\lambda)$ are invariant with respect to the following involutions

$$
L(\phi) \rightarrow-L^{T}(-\phi) \quad \text { and } \quad L_{0}(\lambda) \rightarrow-L_{0}^{T}(-\lambda)
$$

that are compatible with the Cartan involution $\sigma$. Trigonometric Lax matrix has also a standard point symmetry $\phi \rightarrow \phi+n \pi, n \in \mathbb{Z}$.

It is easy to prove that trigonometric Lax matrix $L(\phi)$ (15) satisfies relation

$$
\begin{equation*}
\left\{\frac{1}{L}(\phi), \stackrel{2}{L}(\theta)\right\}=\left[r_{12}(\phi, \theta), \stackrel{1}{L}(\phi)\right]-\left[r_{21}(\phi, \theta), \stackrel{2}{L}(\theta)\right] . \tag{7}
\end{equation*}
$$

with trigonometric $r$-matrix

$$
\begin{align*}
r_{12}(\phi, \theta) & =\frac{\sin \phi \sin \theta}{\cos ^{2} \phi-\cos ^{2} \theta} \sum_{i=1}^{3}\left(\cos \theta H_{i} \otimes H_{i}+\cos \phi Z_{i} \otimes Z_{i}\right.  \tag{8}\\
& \left.-\frac{\sin \phi \cos \theta}{\sin \theta} S_{i} \otimes S_{i}\right)+S_{3} \otimes S_{4}+\frac{\cos \phi \sin ^{2} \theta}{\cos ^{2} \theta-\cos ^{2} \phi} S_{4} \otimes S_{4}
\end{align*}
$$

Here we use the standard tensor notations

$$
\stackrel{1}{L}(\phi)=L(\phi) \otimes 1, \quad \stackrel{2}{L}(\theta)=1 \otimes L(\theta), \quad r_{21}(\phi, \theta)=\Pi r_{12}(\theta, \phi) \Pi
$$

and $\Pi$ is a permutation operator $\Pi X \otimes Y=Y \otimes X \Pi$ of auxiliary spaces. Remark that due to the independent on $\phi$ and $\theta$ item $S_{3} \otimes S_{4}$ in (8) the inequality $r_{21}(\phi, \theta) \neq-r_{12}(\theta, \phi)$ takes place.

If we put $\phi=\varkappa \lambda^{-1}, \theta=\varkappa \mu^{-1}$ and take the limit $\varkappa \rightarrow 0$ one gets rational $r$-matrix for the Kowalevski gyrostat on $e(3)$ algebra 3]

$$
\begin{aligned}
r_{12}(\lambda, \mu) & =\frac{\lambda \mu}{\lambda^{2}-\mu^{2}} \sum_{i=1}^{3}\left(H_{i} \otimes H_{i}+Z_{i} \otimes Z_{i}-\frac{\mu}{\lambda} S_{i} \otimes S_{i}\right) \\
& +S_{3} \otimes S_{4}+\frac{\lambda^{2}}{\lambda^{2}-\mu^{2}} S_{4} \otimes S_{4} .
\end{aligned}
$$

The well known isomorphism $s o(3,2)$ and $s p(4)$ algebras allows us to consider $4 \times 4$ Lax matrix instead of $5 \times 5$ matrix (6). The four generators $Z_{1}, Z_{2}, Z_{3}$ and $S_{4}$ may be represented by different $4 \times 4$ real or complex matrices. Below we give one of the possible forms of the $4 \times 4$ Lax matrix for the Kowalevski gyrostat

$$
\begin{align*}
L_{4}(\phi) & =i\left(\begin{array}{cccc}
-e^{-i \phi} J_{3} & -e^{-i \phi} \varkappa \sin \phi & \cos \phi J_{-} & 0 \\
e^{-i \phi} \varkappa \sin \phi & e^{-i \phi} J_{3} & 0 & -\cos \phi J_{+} \\
\cos \phi J_{+} & 0 & e^{i \phi} J_{3} & -e^{i \phi} \varkappa \sin \phi \\
0 & -\cos \phi J_{-} & e^{i \phi} \varkappa \sin \phi & -e^{i \phi} J_{3}
\end{array}\right)+  \tag{9}\\
& +\varkappa^{-1}\left(\begin{array}{cccc}
0 & y_{-} & 0 & y_{3} \\
-y_{+} & 0 & -y_{3} & 0 \\
0 & y_{3} & 0 & -y_{+} \\
-y_{3} & 0 & y_{-} & 0
\end{array}\right)+\rho \sin \phi\left(\begin{array}{cccc}
-1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & -1 & 0 \\
0 & 0 & 0 & 1
\end{array}\right) .
\end{align*}
$$

Here $J_{ \pm}=J_{1} \pm i J_{2}$ and $y_{ \pm}=y_{1} \pm i y_{2}$.
There are few Lax matrices obtained for different deformations of known integrable systems from their undeformed counterpart in the form (4) (see 2, 3] and references within). The main question in construction of these matrices by the Ansatz $L=Y \cdot L_{0}$ (4) is a choice of a proper matrix $Y$ for a given rational matrix $L_{0}(\lambda)$. In this note we show that this choice is related to transformation of the rational $r$-matrix to the trigonometric one.

The trigonometric $r$-matrix (8) is constant and the corresponding Lax matrix $L(\phi)$ (5) does not contain ordering problem in quantum mechanics. Hence equation (7) holds true in quantum case both for Lax matrices (5) and (91).

Acknowledgments. The authors thank E.K. Sklyanin for very useful conversation on the subject of this paper.
I.V.K. wishes to thank the London Mathematical Society for support his visit to England and V.B. Kuznetsov for hospitality at the University of Leeds.
