(Dated: April 16, 2024)

The G lauber theory has been used to investigate the reaction cross section of proton-rich nucleus 23 Al. A core plus a proton structure is assumed for 23 Al. HO-type density distribution is used for the core while the density distribution for the valence proton is calculated by solving the eigenvalue problem of W oods-Saxon potential. The transparency function in an analytical expression is obtained adopting multi-G aussian expansion for the density distribution. C oulom b correction and nite-range interaction are introduced. This modil ed G lauber model is apt for halo nuclei. A dom inate s-wave is suggested for the last proton in 23 Al from our analysis which is possible in the RM F calculation.

PACS num bers: 25.60 D z, 24.10.-i

Interest in reaction cross section $(_{\rm R})$ has grown over the last decades with the developm ent of radioactive ion beam s (R IB s). R for light exotic nuclei has been studied extensively both theoretically and experim entally. Up to now much e ort has been devoted to the study of neutron halo structure, such as the discovery of neutron halo nuclei^{6;8}He, ¹¹Li, ^{11;14}Be [1] and the recent work on ¹⁹C [2, 3]. At the same time, some work has been performed on proton halo nuclei, e.g.⁸B and ¹⁷Ne.Due to Coulom b e ect, the form ation of proton halo is more di cult and complicated compared to neutron halo structure. And discrepancies were found in proton halo nuclei, especially on ⁸B [4, 5, 6, 7]. Recently the _R was measured for the proton halo candidate ²³A l, whose separation energy of the last proton is very small (0.125 MeV) [8]. Enhancement in $_{\rm R}$ was observed for 23 A l compared to its neighbors [9, 10]. According to the shellm odel, the last proton in 23 Al is in the $1d_{5=2}$ orbit. But the RMF calculation shows that it is possible to have the inversion of the $1s_{1=2}$ and $1d_{5=2}$ orbit in ²³Al [11]. Thus it is very interesting and important to know which orbit the last proton occupies.

Several methods are available to study the total reaction cross section, i.e. the multi-step scattering theory of G lauber [12], the transport model method of M a et al. [13] and the sem i-empirical formula of K ox et al. [14] and Shen et al. [15] etc. For the rst one, the optical lim it approximation of the G lauber approach is the most common used method [12]. In the high energy domain, the G lauber model is based on the individual nucleonnucleon collisions along the classical straight-line trajectory in the overlap volume of the colliding nuclei [12, 16]. This model has been extended to low energies by taking into account the C oulom b distortion of the eikonal trajectory [17]. Recently, it has been found that the G lauber model always underestimates $_{\rm R}$ by 10–50% at intermediate energies, if one assumes HO -type nucleon density distributions and determines the width parameter by reproducing the interaction cross section at relativistic energies [18]. To improve the calculation of the G lauber model at low energies, the nite-range interaction was considered and its energy dependence was investigated by

tting the $_{\rm R}$ of $^{12}\rm{C}$ + $^{12}\rm{C}$ from low to high energies [19]. And also the few body G lauberm odel was widely used to study nucleiw ith halo structure, which assum es core plus one-(two-)nucleon structure [20]. However, all these calculations are done by solving a multi-dim ensional num erical integration or M onte-C arlo simulation. To sim plify the calculation, the G lauber m odel in an analytical form has been obtained if we use G aussian function for density distributions [17]. But this method can only be used to describe stable nuclei. In order to study nuclear reaction involving exotic nuclei, the separation energy dependent di useness was introduce into this method [21]. Here we present a more general analytical form by expanding the density distributions of projectile and target using multi-Gaussian functions, which can be used to calculate $_{\rm R}$ for both stable nuclei and nuclei with halo structure.

To begin with, we describe the formulation of $_{\rm R}$ in the fram ework of G lauber model in the optical lim it approximation. If we distinguish neutrons and protons in the projectile and target, the reaction cross section can be expressed as

$$z_{1}$$

 $R = 2$ [1 T (b)]bdb (1)

where $T \ (b)$ is the transparency function at impact parameter b

$$Z \qquad X$$

T (b) = expf dr f (r r⁰)
 $i=n_{r}p$

$$\begin{array}{c} x \\ \underset{ij P_i}{\overset{z}{}}(r) \underset{T_j}{\overset{z}{}}(r^0 \ b) dr^0 g \qquad (2) \\ \end{array}$$

here f (r) is the nite-range function

$$f(r) = \frac{1}{\frac{2}{0}} \exp(\frac{r^2}{\frac{2}{0}})$$
(3)

with $_0$ being the nite-range parameter. $_{ij}$ is the nucleon-nucleon collision cross section. $_{ij}^z$ is the neutron (proton) density distribution in the projectile (target) with the z axis integrated [17]. With the input density distribution of the projectile and target, the reaction cross section can be obtained after the multi-dimensional numerical integration.

If we assume G aussian distributions for the density of projectile and target, which is suitable for light stable nuclei. Then we can obtain an analytical transparency function [17]. To extend this method for both stable nuclei and halo nuclei with a long tail in the density distribution, we express the density distribution by N G aussian functions

$$\lim_{\substack{ij \ ij \ k=1}} \frac{X^{N}}{\sum_{j=1}^{k} (0) e^{(r=a_{jj}^{k})^{2}} \quad (i=P,T; j=n,p)$$
(4)

where ${}^{k}_{ij}(0)$ and a^{k}_{ij} are the amplitude and width param – eters of the Gaussian functions. Then the transparency function can be written in an analytical form similarly [17, 21]

$$T (b) = \exp f \frac{2 X X X^{N} X^{N}}{\sum_{j=n,p}^{j=n,p} \sum_{k=1}^{k} \sum_{k=1}^{j=n,p} \sum_{k=1}^{j=n,$$

where b^0 is the impact parameter after considering $C\,ou\,lom\,b$ correction

$$b^{02} = \frac{b^2}{1 \quad V_c = E_{CM}} = \frac{b^2}{1 \quad 1:44Z_P Z_T = (R_{int} E_{CM})}$$
(6)

here Z_P (Z_T) refers to the charge number of the projectile (target), R_{int} is the interaction radius and E_{CM} is the incident energy in the center of mass frame [17].

To investigate the $_{\rm R}$ of 23 A l, we assume a core ℓ^{22} M g) plus one proton structure since the weak bind between the last proton and the core. HO-type distribution is used for the core density. The density distribution for the valence proton was calculated by solving the eigenvalue problem of W oods-Saxon potential [22]

$$\frac{d^{2}R(r)}{dr^{2}} + \frac{2}{h^{2}}\mathbb{E} \quad U(r) \quad \frac{1(l+1)h^{2}}{2r^{2}}\mathbb{R}(r) = 0$$

$$U(r) = V_{0}f(r) + V_{ls}(L \quad s)\frac{d^{2}}{dr}\frac{1}{r}\frac{d}{dr}f(r) + V_{Coul}$$
(7)

where $f(r) = [1 + \exp(\frac{r - R}{a})]^{-1}$ with $R = r_0 A_c^{1=3}$ (V_{ls} = 17M eV). V₀ is the depth of potential, V_{Coul} is the Coulom b potential. In the calculation the di useness (a) and radii parameter (r₀) were chosen to be 0.67 fm and 1.27 fm [23].

First we assume HO-type distribution for the 12 C target and determ ine the HO width parameter by reproducing the interaction cross section of 12 C + 12 C at relativistic energy. Then the $_{\rm R}$ for 12 C + 12 C at di erent energies are calculated and compared them with experimental data. In the calculation, the nite-range parameter was taken from Ref. [19].

$${}^{2}_{0} = 2 {}^{2}$$

= 0:996 exp ($\frac{E}{106:679}$) + 0:089 (8)

where E is the incident energy in the laboratory frame in M eV .W ith the consideration of the energy dependent

nite-range interaction, the underestimation at low energies in the zero-range G lauber model was removed as described in Ref. [19]

TABLE I: The reaction cross sections for $^{\rm 22}{\rm M}$ g and $^{\rm 23}{\rm A}\,{\rm lw}$ ith carbon target.

| Nuclei | energy (| /AMeV | 7) | R | (m b) | reference |
|-------------------|----------|-------|----|------|-------|-----------|
| ²² M g | 33 | .4 | | 1531 | 125 | [9] |
| ²³ Al | 35 | .9 | | 1892 | 145 | [9] |

Then we assume HO distribution for the 22 Mg core, and adjust the HO width parameter to the measured $_{\rm R}$ at 33.4A MeV as given in Table. I.

FIG. 1: Density distributions of 22 M g and 23 Al. The dotted line is the density distribution of 22 M g. The solid and dashed line are the density distribution of 23 Al in s- and d-wave, respectively. For comparison, the density distribution of 23 Al in the s-wave calculated by multi-G aussian expansion (Eq.(4)) is also plotted as the dotted-dashed line. It is alm ost overlapped with the original density distribution.

Since spin parity assignment for the ground state of 23 Al is unknown experimentally, we took the assumed value $(1/2^+)$ from Ref.[10]. The mixing conguration for the last proton was considered as following

$$/ \frac{p}{f} \frac{f^{2}M}{f^{2}M} \frac{g(0^{+})}{g(2^{+})} \frac{s_{1=2}}{s_{1=2}} J_{J=1=2^{+}}$$

$$+ \frac{p}{1} \frac{f^{2}M}{f} \frac{f^{2}M}{f^{2}} \frac{g(2^{+})}{g(2^{+})} \frac{s_{1=2}}{s_{1=2}} J_{J=1=2^{+}}$$
(9)

where f (0 f 1) denotes the relative s-wave spectroscopic factor. $s_{1=2}$ (r) and $d_{5=2}$ refer to the wavefunction of s-and d-wave. The density distribution of the valence proton can be calculated by 2 (r). The wavefunction for the valence proton in $2s_{1=2}$ or $1d_{5=2}$ orbit was calculated by adjusted the depth of W oods-Saxon potential to reproduce the separation energy of the last proton in ^{23}Al . The density distribution of ²³Alwas obtained by adding that of the core and the valence proton. For sim plicity, we used the same density distributions for both the ground (0^+) and excited (2^+) states of ²²M g. C om parison of ²³A I's density distributions in s- and d-wave with the core was shown in Fig.1. From the gure, the density distributions of 23 Alare larger than that of 22 Mg. The tail of s-wave is much longer than d-wave. In the expansion, we used 12 G aussian functions for the projectile and 4 G aussian functions for the target density distribution. In the tting, 2 is less than 10 9 . As we can see in Fig.1, good agreem ent between the original and tted density was obtained.

FIG.2: Transparency function (T (b)) for 23 Alin the s-wave on 12 C target at 35.9A M eV.The dotted line is calculated by the G lauber m odel in the optical lim it approximation. The dashed line is the results with nite-range interaction. And the solid line is calculation by the G lauber m odel with both nite-range interaction and C oulom b correction.

W ith the G aussian parameters, we can directly calculate the transparency function (T (b)) using Eq.(5). The e ect of nite-range and C oulom b correction on T (b) was compared in Fig. 2. As we can see, T (b) is saturated to unity as the impact parameter increase. C om pared with the G lauber m odel in the optical limit approxim ation, the nite-range e ect m akes T (b) decrease slower as the decrease of the in pact param eter which leads to larger reaction cross section. But the C oulom b correction m akes T (b) decrease faster as the decrease of the in pact param eter.

Dependence of the reaction cross section on the s-wave spectroscopic factor was calculated and shown in Fig. 3. The $_{\rm R}$ of ²³Al was also plotted [9]. It is found that within the uncertainties our analysis suggests dom inate s-wave for the last proton in ²³Al. The lower lim it of the s-wave spectroscopic factor is around 0.65. But it should be pointed out that the error of $_{\rm R}$ for $^{23}{\rm Al}$ is com parable with the di erence in $_{\rm R}$ between s- and d-wave. And even the s-wave calculation still underestim ates the experimental R data. Zhao et al. suggested an enlarged core in ²³Alwhich lead to larger reaction cross section [24]. That m aybe one of the reasons for the underestimation in our calculations. In order to obtain more con mative conclusion, much more precise measurement and theoretical study of $_{\rm R}$ for ²³Alis required. And the measurement of momentum distribution for the residue after one-proton rem ove is expected which is much easy to distinguish s- and d-wave.

For com parison, we also assume HO core plus Yukawasquare tail for the density distribution of 23 A land determ ine the parameters by reproducing the experimental $_{\rm R}$. The Yukawa-square tail is known to be a good approximation to the shape of a single-particle density at the outer region of a core with centrifugal and C oulom b barriers [6]. The assumed density is written as

$$(r) = \begin{array}{c} HO - type & (r < r_c) \\ Y exp(r) = r^2 & (r - r_c) \end{array}$$
(10)

FIG.3: Dependence of the reaction cross section on the s-wave spectroscopic factor. The shaded area comes from the experimental error of $^{22}M\,g$ and $^{23}A\,l's_{R}$ data. The dot is the $_{R}$ of $^{23}A\,l$.

FIG. 4: Density distributions of 23 Al. The solid and dashed line are the density distribution of 23 Al in s- and d-wave, respectively. The thick line is the extracted density distribution assuming HO plus Yukawa distribution. The shaded area is the error from the experimental R data.

where $r_{\rm c}$ is the crossing point of these two functions, the factor Y is to keep the equality of the two distributions at $r_{\rm c}$. The width parameter of the HO-type core is tted to the $_{\rm R}$ of $^{22}{\rm M}$ g. Then the parameters and $r_{\rm c}$ are tted to the $_{\rm R}$ of $^{23}{\rm Algiven}$ in Table. I with an addi-

In Fig.4, the extracted density distribution was compared with the calculated density for 23 Al in s- and d-wave. The extracted density is closer to s-wave than d-wave. It demonstrates a long tail in the density distribution and supports the conclusion that the s-wave is dominate for the last proton in 23 Al.

In summary, the G lauber theory has been used to investigate the reaction cross section. Adopting multi-Gaussian expansion for the density distribution of projectile and target, an analytical form for the transparency function was deduced. The energy dependent nite-range interaction and Coulomb correction were considered. It has been pointed out that this modi ed G lauber model is suitable for studying the $_{\rm R}$ of both stable nuclei and nucleiw ith exotic structure. W e used this model to study the reaction cross section of proton-rich nucleus ²³Al. A core plus proton structure was assumed for ^{23}Al HO type density distribution was used for the core while the density distribution for the valence proton was calculated by solving the eigenvalue problem of W oods-Saxon potential. The s- and d-wave mixing con guration was studied. Density distribution was extracted for ²³Alassum ing HO plus Yukawa-square tail. A dom inate s-wave was suggested in our analysis which indicates a proton halo structure in ²³Al.
