#### Abstract

In the context of com plex system $s$ and, particularly, of protein folding, a physically $m$ eaningfiul distance is de ned which allow s to $m$ ake useful statistical statem ents about the w ay in which energy di erences are modi ed when tw o di erent instances of the sam e potentialenergy function are used. W hen the two instances arise from the fact that di erent algorithm s or di erent approxim ations are used, the distance herein de ned $m$ ay be used to evaluate the relative accuracy of the two $m$ ethods. $W$ hen the di erence is due to a change in the free param eters of w hidh the potential depends on, the distance can be used to quantify, in each region ofparam eter space, the robustness of the $m$ odeling to such a change and this, in tum, $m$ ay be used to assess the signi cance of a param eters' $t$. B oth cases are ilhustrated $w$ ith a practical exam ple: the study of the P oisson \{based solvation energy in the T rp \{C age protein ( PDB code 1L2Y).

## 1 Introduction

Them ost fundam ental way to account for the behaviour of a physical system is through its energy function $H$ ( $q ; p$ ), which depends on the coordinates $q$

[^0]and the $m$ om enta $p$ of all the particles. In nom al situations, this function can be expressed as the sum of the kinetic energy $K(q ; p)^{1}$ and the potential energy $V(\mathrm{q})$. Since the form er is of general form for any type of system and, norm ally, it does not a ect the equilibrium properties, the latter is enough for a com plete characterization of the problem .

U nder $m$ ost real circum stances, the exact form of $V(q)$ is unknown and one is forced to seek an approxim ation $V^{\text {app }}$ ( $q$ ). This $m$ ay be done, for physical system $s$ that are signi cantly com plex, by assum ing that the relevant interactions included in $V$ (q) can be form ally factorized [1]. Then, an approxim ated function $V_{i}^{\text {app }}(\mathrm{q})$ is devised according to heuristic and sem iem pirical reasons to account for each of the original parts $\mathrm{V}_{\mathrm{i}}(\mathrm{q})$ :

$$
\begin{equation*}
V(q)={\underset{i=1}{x^{n}} V_{i}(q){ }_{i=1}^{x_{i}^{m}} V_{i}^{a p p}(q): ~: ~}_{i=1} \tag{1}
\end{equation*}
$$

For exam ple, in the study of proteins [2,3], which are a very relevant case of com plex system $s$, som e of the term $s$ in which the total potentialenergy function is traditionally factorized are the hydrogen-bonds energy, the $V$ an der W aals interaction, the excluded-volum e repulsion, the C oulom b energy and the solvation energy. This last interaction, which is one of the $m$ ost challenging term $s$ of $V(q)$ to $m$ odel, is custom arily further split into electrostatic and non-electrostatic parts $[4,5]$. It is the form er which is studied in section 3 to illustrate the application of the concepts herein discussed.

Retuming to the general case, let us assum e that a particular energy term $V_{j}(q)$ in eq. 1 and its approxim ated countenpart $V_{j}^{\text {app }}(\mathrm{q})$ correspond to the part of $V(q)$ that is going to be studied or $m$ odeled. Let us denote that term $V_{j}(\mathrm{q})$ by $V$ (q) and, correspondly, $\mathrm{V}_{\mathrm{j}}^{\text {app }}$ (q) by $\mathrm{V}^{\text {app }}$ (q) in the forecom ing reasoning. $C$ learly, if the approxim ated function $V^{\text {app }}$ (q) is too distant from the original $V$ ( $(9)$, it $w$ ill be useless, as this di erence $w i l l$ certainly propagate to the total potential energy. Therefore, one must precisely de ne and calculate this distance, depending on the type of system which is the ob ject of the study and on the particular aspects that are going to be investigated. T he situation is further com plicated when subsequent approxim ations to $V$ app (q) are done, usually w ith the aim of lessening the num erical com plexity and rendering the sim ulations feasible.

This yet-unde ned distance between potentialenergy functions $m$ ay also be useful in another situation which is often found in the study of com plex system s: param eter tting. A ny reasonable functionalform ofa certain term V (q) of the total potential energy (or of its approxim ation $V^{\text {app }}$ (q)) is a simpli ed

[^1]m odel of physical reality and it contains a num ber of free param eters. T hese param eters, which, in $m$ ost of the cases, are not physically observable, m ust be $t$ against experim ental or $m$ ore ab initio results prior to using the function for practical purposes. For exam ple, in the continuum solvation models based on the solution of the Poisson equation $[5,6,7,8]$, typical free param eters are the dielectric constants and the position of the surface that separates the outer high \{dielectric $m$ edium from the inner low \{dielectric one. A though they are custom arily assigned standard values (such as $p=1$ for the dielectric constant of the protein, w $=80$ for the dielectric constant of the aqueous $m^{m}$ edium ${ }^{2}$, and the M olecular Surface (MS), de ned by C onnolly [9], for the surface of separation), we believe that they $m$ ust be $t$ in order to render calculations $m$ ore accurate. C ertainly, for other potential-nergy functions, such as the ones found in force elds like CHARMM [10,11], the $t$ of the free param eters is com m on practice.

In order for any $t$ to yield statistically signi cant values of the param eters, the particular region of the param eter space in which the nal result lies must have the property of robustness, i.e., it $m$ ust occur that, if the found set of param eters' values is slightly changed, then, the relevant characteristics of the potentialenergy function which depends on them are also approxim ately kept unm odi ed. If this were not the case, a new $t$, perform ed using a di erent set of experim ental (or m ore ab initio) points, could produce a very distant potential. T his last scenario is, clearly, undesirable. T herefore, it m ay be useful to evaluate the robustness of the, a priori, reasonable regions of param eter space for the potentialenergy function that is to be used. To accom plish this, one must again de ne a relevant distance betw een two instances of the sam e potentialw ith di erent values of the param eters.

In section 2, a meaningful distance that can be used in the two situations aforem entioned is de ned and justi ed. In section 3, within the context of the protein folding problem and as an exam ple of the rst application discussed, this distance is $m$ easured between instances of the P oisson \{based solvation energy arising from the choioe of di erent grid sizes in the nite-di erences algorithm with which it is calculated. To ilhustrate the second possible use of the distance, the robustness of the P oisson energies to changes in som e of its free param eters, holding the grid size $x e d$, is quanti ed. This analysis is necessary to assess the signi cance of the param eters' values determ ined through a t. Finally, section 4 is devoted to the conclusions.

[^2]
## 2 D istance criterium

Let $V$ (q) be a particular term of the potential energy of a system. The nu$m$ erical value of this physical quantity for each conform ation of depends on tw o conceptually di erent inputs: on one hand, the algorithm or approxim ation used to com pute it, denoted by A; on the other hand, the values of the free param eters $P$. C hanges in these inputs produce di erent instances of the physical quantity $V$ ( $(9)$, which we denote by subscripting $V$. For exam ple, if the algorithm is held constant and two di erent set of param eters $\mathrm{P}_{1}$ and $\mathrm{P}_{2}$ are used, our notation $m$ ade explicit would read as in the follow ing equation (an analogous de nition $m$ ay be $m$ ade if the algorithm is held constant and the param eters are varied).

$$
\begin{equation*}
\mathrm{V}_{1}(\mathrm{q}):=\mathrm{V}\left(\mathrm{~A} ; \mathrm{P}_{1} ; \mathrm{q}\right) \quad \text { and } \quad \mathrm{V}_{2}(\mathrm{q}):=\mathrm{V}\left(\mathrm{~A} ; \mathrm{P}_{2} ; \mathrm{q}\right): \tag{2}
\end{equation*}
$$

Now, a usefiul and physically meaningful de nition of a distance $d\left(V_{1} ; V_{2}\right)$ is sought betw een a pair of instances, such as the ones in the previous equation, of the sam e potential-energy function.

In som e cases traditionally studied in physics, the dependence of $V$ on the param eters is simple enough to allow a closed functional dependence $V_{2}\left(V_{1}\right)$ to be found ${ }^{3}$. H ow ever, in the study of com plex system $s$, such as proteins, this dependence is often $m$ uch $m$ ore com plicated, due to the high dim ensionality of the conform ational space and to the fact that the energy landscape lacks any evident sym $m$ etry. The set $C\left(V_{1}\right)$ of the conform ations $w$ ith a particular value of the potential energy $V_{1}$ typically spans large regions of the phase space containing structurally di erent conform ations. W hen an approxim ation is perform ed or the algorithm is changed, from $A_{1}$ to $A_{2}$, or the free param eters are shifted, from $P_{1}$ to $P_{2}$, each conform ation q in $\mathrm{C}\left(\mathrm{V}_{1}\right)$ is a ected in a di erent way and its new energy $V_{2}(\mathrm{q})$ is m odi ed in a m anner that does not depend trivially on the particular region of the phase space which the conform ation $q$ belongs to. T herefore, a sim ple functional relation $V_{2}\left(V_{1}\right)$ is no longer possible to be found: for each value of $V_{1}$, there corresponds now a whole distribution of values of $V_{2}$ associated $w$ th conform ations which share the sam $e$ value of $V_{1}$ but which are far apart in the conform ational space. M oreover, the pro jection of this high \{dim ensional q\{space into the 1 \{dim ensional $V_{1}$ \{space $m$ akes $V_{2}$ look as a random variable for each particular value of $V_{1}$ (see g.1).W e then

3 For exam ple, if the $m$ ass of a harm onic oscillator is changed from $m_{1}$ to $m_{2}$, the potential energy functions $w$ ill satisfy the linear relation $V_{2}(q)=\left(m_{1}=m_{2}\right) V_{1}$ (q) for all the conform ations of the system; if the the atom ic charges are rescaled by a factor (being actually $Q_{i}$ ) and is changed from 1 to 2 , the free energies of solvation calculated via the P oisson equation will, in tum, satisfy the linear relation $V_{2}(\mathrm{q})=\left({ }_{1}=2\right)^{2} \mathrm{~V}_{1}(\mathrm{q})$, etc.

Fig. 1. Illustration of the functions de ned in eq. 3. Each point corresponds to a single conform ation $G_{i}$ of the system, being $V_{1}\left(G_{i}\right)$ its $x\left\{c o o r d i n a t e\right.$ and $V_{2}\left(G_{i}\right)$ its $y\{c o o r d i n a t e . ~ I n ~ t h e ~ z\{a x i s, ~ t h e ~ p r o b a b i l i t y ~ d e n s i t y ~ o f m ~ e a s u r i n g ~ a ~ p a r t i c u l a r ~ v a l u e ~$ of $V_{2}$ for each value of $V_{1}$. Two norm aldistributions representing this quantity are show $n$ at arbitrary positions in the $x\{a x i s . T$ he continuum line represents the $m$ ean $V_{2}\left(V_{1}\right)$ of the values $V_{2}(q) w$ th $q 2 C\left(V_{1}\right)$ as a function of $V_{1}$. The broken lines enclose the region where there is the largest probability to nd a conform ation if a single num erical experim ent is perform ed (around 68\% if the distribution of $V_{2}$ is assum ed to be norm al for each $V_{1}$ ).
de netwo realfunctions, $V_{2}\left(V_{1}\right)$ and $\left(V_{1}\right)$, which correspond to the $m$ ean and to the standard deviation, respectively, of this random variable as a function of $V_{1}$ ( $w$ here the average $h i$ is de ned to be taken over the conform ations q $\left.2 C\left(V_{1}\right)\right)$ :

$$
\begin{equation*}
V_{2}\left(V_{1}\right)=h V_{2}(q) i \quad \text { and } \quad\left(V_{1}\right):=\overline{h\left(V_{2}(q) \quad h V_{2}(q) i\right)^{2} i}: \tag{3}
\end{equation*}
$$

It can be proved, from their de nition, that these tw o functions are continuous irrespectively of the particular characteristics of $\mathrm{V}_{1}$ (q) and $\mathrm{V}_{2}$ (q) (given that both of them are sm ooth functions of the conform ation). It $m$ ay also be show $n$ that, under assum ptions which are typically ful led in real cases, $V_{2}\left(V_{1}\right)$ and $\left(V_{1}\right)$ are also di erentiable. Thus, when restricted to a nite intervalof $V_{1}$, the linear dependence given by the follow ing equation $m$ ay hold approxim ately:

$$
\begin{equation*}
\mathrm{V}_{2}\left(\mathrm{~V}_{1}\right)^{\prime} \mathrm{bV}_{1}+\mathrm{a}:=\mathrm{b}\left(\mathrm{~V}_{1}+\mathrm{V}_{1}^{0}\right): \tag{4}
\end{equation*}
$$

In fact, for the aforem entioned cases in which the dependence of the potential energy on the param eters is sim ple enough (see footnote 3), eq. 4 holds exactly and, being able to describe $V_{2}\left(V_{1}\right)$ by a closed analytical form ula, b and a can be exactly com puted ${ }^{4}$. However, in a general situation, the functions

[^3]de ned in eq. 3 are im possible to be calculated analytically and so are the param eters $b$ and $a$ in the linear approxim ation of $V_{2}\left(V_{1}\right)$. In such a case, one $m$ ay at $m$ ost have a nite collection of $n$ conform ations $f q_{i=1}^{n}$ and the respective values of $V_{1}\left(q_{i}\right)$ and $V_{2}\left(q_{i}\right)$ for each one of them. These data, for a particular $i$, should be thought as a single num erical experim ent in the already suggested sense that, if one regards $V_{1}\left(q_{i}\right)$ as an independent variable, the outcom e of the dependent variable $V_{2}\left(q_{i}\right)$ is basically unpredictable and $V_{2} m$ ay be regarded as a random variable param etrically dependent on $V_{1}$ (see g.1). From this nite know ledge about the system, one $m$ ay statistically estim ate the values of $b$ and $a$. If the standard deviation $\left(V_{1}\right)$ is a constant (i.e., it does not depend on $V_{1}$ ), which, for the particular system studied in this work, has been found to be approxim ately true, then, the least-squares $m$ axim um likelihood $m$ ethod [12,13] yields the best estim ates for $b$ and $a^{5}$ under very general conditions, such as independence of the random variables and norm al distribution. M oreover, it $m$ ay be show $n[12,13]$ that the best estim ate for the standard deviation (see footnote 5) is given by the follow ing expresion:
$T$ his quantity $m$ ay be regarded as a random error that arises in the transit from $V_{1}$ to $V_{2}$. In the sam e sense, a $m$ ay be regarded as a system atic error and, since it is equivalent to an energy reference, its actual value is not relevant for the forecom ing discussion. The slope b and are the two quantities involved in the de nition of the distance $d\left(V_{1} ; V_{2}\right)$, which is the œentralconcept introduced in this paper (see eq. 8 below). In order to render this de nition meaningful, we are going to evaluate how energy di erences arem odi ed, when going from $V_{1}$ to $V_{2}$, as a function ofb and. This di erences are the relevant physical quantities if one's aim is to study the conform ational behaviour of a system .

U nder the approxim ations of linear $V_{2}\left(V_{1}\right)$ dependence and constancy of $\left(V_{1}\right)$, $g .1$ becom es the left part of $g$. 2 . In the right side of the sam e gure, one of the w orst cases (i.e., one case for which $d\left(V_{1} ; V_{2}\right)$ is one of the largest) studied in section 3 is depicted to show that the hypothesis are approxim ately ful led for the particular protein system investigated there.

N ow, let us focus on two arbitrary conform ations of the system (see the left side of $g .2$ ). For them, the $V_{2}$ fenergy di erence $V_{2}$ is a random variable
note 3, a function $V_{2}\left(V_{1}\right) m$ ay be found algebraically. This is, how ever, consistent. If one thinks that, in these system s , the spread $\left(\mathrm{V}_{1}\right)$ is zero, the relation found algebraically and the one that stem $s$ from the average are identical.
5 The same letters are used for the ideal param eters $b, a$, and and for their least-squares best estim ates, since the only know ledge that one $m$ ay have about the form er com es from the calculation of the latter.

Fig. 2. The graphic on the left is an illustration of the distance criterium . The best linear $t$ is depicted by a continuum line. The broken lines correspond to the estim ated standard deviation of the points in the $\mathrm{V}_{2}$ direction. The $\mathrm{V}_{1}\{$ and $\mathrm{V}_{2}$ fenergy di erences, $\mathrm{V}_{1}$ and $\mathrm{V}_{2}$, betw een two particular conform ations, as well as the distance $d$ for $=1$ (see eq. 8) are also show $n$. The graphic on the right is a particular exam ple taken from the system studied in section 3. The di erence between the $V_{1}$ and $V_{2}$ instances is a sm allm odi cation of the surface of separation between dielectrics. 150 conform ations of the investigated protein are show $n$.
param etrically dependent on the $\mathrm{V}_{1}$ \{energy di erence $\mathrm{V}_{1}$ (which is assum ed to be regular num ber, i.e., a random variable w ith zero variance ${ }^{6}$ ). T he probability density of this random variable is found by assum ing that $V_{2}$ is nom ally distributed w th $m$ ean $V_{2}\left(V_{1}\right)$ and standard deviation. $T$ hen, the distribution of $V_{2}$, for each $V_{1}$, is nom alw ith $m$ ean $b V_{1}$ and standard deviation $\overline{2}^{7}$ :

$$
\begin{equation*}
P\left(V_{2} ; V_{1}\right)=p \frac{1}{2}(\overline{2}) \exp \frac{\left(V_{2} p b_{1}\right)^{2}}{2(\overline{2})^{2}}: \tag{6}
\end{equation*}
$$

If the random errors w ere negligible (as in the system s discussed in footnote 3) and one wanted to calculate the value of $V_{1}$ from the know ledge of $V_{2}$, the identity $\quad V_{1}=\quad V_{2}=b$ would have to be used. $W$ hen there are signi cant random errors, the situation is equivalent except for the fact that there is a probabilistic indeterm ination, i.e., from them easured value of $V_{2}, V_{1}$ can be no longer in ferred. It follow s directly from eq. 6 that, the quantity $V_{2}=b$ is a pandom variable nom ally distributed $w$ th $m$ ean $V_{1}$ and standard deviation $\overline{2}=$ =bj (see footnote 7):

$$
\begin{equation*}
P\left(V_{2}=\mathrm{b} ; \mathrm{V}_{1}\right)=\mathrm{p}_{\overline{2}} \mathrm{p}_{\left.\overline{2}=\frac{1}{\mathrm{~b}}\right)} \exp \quad \frac{\left(\mathrm{V}_{2}=\mathrm{b} \quad \mathrm{~V}_{1}\right)^{2}}{2(\overline{2}=\mathrm{b})^{2}} \text { : } \tag{7}
\end{equation*}
$$

[^4]Now, let us de ne the distance $d\left(V_{1} ; V_{2}\right)$ between two instances of the sam $e$ potential energy as follow $s^{8}$ :

W here $b$ and a are those calculated from a least-squares $t$ of the values of $V_{2}\left(q_{i}\right)$ against $V_{1}\left(q_{i}\right)$ and is a positive proportionality factor yet to be xed (see point 3 below ).

This de nition encodes som e intuitions that one $m$ ay have about the loss of inform ation involved in the transit from $V_{1}$ to $V_{2}$. Let us rem ark some im portant properties which ilhustrate this fact:
(1) If the slope $b$ is nonzero and the random error is zero, $d\left(V_{1} ; V_{2}\right)=0$ and there is no loss of inform ation. A $n$ exam ple of this situation is given by the sim ple system $s$ in footnote 3: clearly, no loss of inform ation $m$ ay be involved in changing the $m$ ass of an harm onic oscillator.
(2) If the random error is di erent from zero and the slope $b$ goes to zero, $\mathrm{d}\left(\mathrm{V}_{1} ; \mathrm{V}_{2}\right)!1$ and the loss of inform ation is com plete. O ne m ay picture this situation by making the best- t line in g. 2 horizontal. In such a case, when two num erical experim ents are perform ed, the probability distribution ofm easuring $V_{2}$ does not depend on $V_{1}$ (it is norm alw ith zero $m$ ean) and the inform ation about $V_{1}$ is im possible to recover.
(3) For interm ediate cases in which both $b$ and are nonzero, all the inform ation about $V_{2}=b$ is found in its probability-density function (see eq. 7) and $m$ any probabilistic statem ents $m$ ay be $m$ ade. For exam ple, it would be desirable that the sign of $V_{2}=b$ had a high probability ofbeing equal to the sign of $V_{1}$. This would typically keep the correct energy ordering of the conform ations when going from $V_{1}$ to $V_{2} . M$ aking the variable change $\mathrm{x}=\mathrm{V}_{2}=\mathrm{b} \quad \mathrm{V}_{1}$ in eq. 7 , one nds that this probability is given by the follow ing equation (assum ing, w ithout loss of generality, that $V_{1}>0$ ).

For a same value of $V_{1}$, this probability decreases $w$ ith $d$; if $d$ is held constant, it increases w ith $\mathrm{V}_{1}$ (the m inim um being $\mathrm{P}_{\text {ordering }}=1=2$, either for $V_{1}$ ! 0 or for $d!1$ ). If $d$ is $s m a l l$, the probability of the

8 A though a negative value ofbm ay look physically perverse, there is no theoretical draw back about it and the possibility is allowed. In fact, if the random errors were sm all and bwas not very sm all in absolute value, the loss of inform ation (see the forecom ing discussion) in going from $V_{1}$ to $V_{2}$ would be sm all.
ordering being $m$ antained is large, even for pairs of conform ations that are close in $\mathrm{V}_{1}$ \{energy. For exam ple, if one takes $=1$, it happens that, if $V_{1}>d$, then, $P_{\text {ordering }}>76 \%$; if $V_{1}>2 d$, then, $P_{\text {ordering }}>92 \%$, etc. A ny other choice of would only yield di erent num erical values for this bounds on $\mathrm{P}_{\text {ordering }}$; the qualitative facts would be preserved. H ow ever, since this values are natural (the norm al distribution varies rapidly and one would easily get very large or very sm all probabilities), the choice
$=1$ is considered to be the m ost convenient herein and it is the one to be used in section 3.
(4) The properties stated in the previous point are direct consequences of the $m$ ore general fact that, as decreases, so dpes the standard deviation of the random variable $\mathrm{V}_{2}=\mathrm{b}$ (which equals $\overline{2} \mathrm{~d}=$ ) and the distribution becom es sharper around the average $V_{1}$ (see eq. 7). That is, the sm aller the value of $d$, the larger the probability of $V_{2}=b$ being close to the perfect value $V_{1}$.

This $m$ easure of the distance betw een two instances of a potential energy presents som e advantages. On one hand, if the approxim ations on which it is based (norm al distribution of $V_{2}$ for each $V_{1}$, linear $V_{2}\left(V_{1}\right)$ dependence, constancy of $\left(V_{1}\right)$ and zero variance in the $m$ easures of $V_{1}$ ) are reasonable, the statistical statem ents derived from a particular $d$ value are $m$ eaningfiul and precise. On the other hand, this statem ents refer, like the ones in the points discussed above, to the whole conform ational space. H ow ever, we would like to stress that, in this work, we are not going to give any criterium to decide whether a particular value of d is su ciently sm all for an approxim ation $V_{1}$ ! $V_{2}$ to be valid or for the system to be robust to changes in the free param eters. Such a decission must be taken depending on the particularities of the system studied (which are encoded in the total potential energy function $\mathrm{V}(\mathrm{q})$ ) and on the questions sought to be answ ered. O ur de nition of $\left(\mathrm{V}_{1} ; \mathrm{V}_{2}\right)$, being based in characteristics shared by $m$ any com plex system $s$, is of general application. For exam ple, we are not going to establish any lim it on the accuracy required for a potentialenergy function to successfiully predict the folding of proteins [2,3]. W e consider this question a di cult theoretical problem and we believe that it $m$ ay be possible a priori that som e special features of the energy landscapes of proteins (such as fiunnel\{ like shape) are the $m$ ain responsible of the high e ciency and cooperativity of the folding process [2,3]. If this were the case, a di erent procedure form easuring the distance betw een potentialenergy functions could be devised [14,15,16], as any approxim ation which does not signi cantly alter these special features would be valid even if the value of d is very large. H ow ever, for the sake of sim plicity, it w illbe assum ed, herein and in section 3 that a transit $V_{1}!V_{2}$ between instances of the sam $e$ potential whose $d\left(V_{1} ; V_{2}\right)$ value is of the order of the them al uctuations R T
is acceptable ${ }^{9}$.
The last point that we m ust rem ark in this section is that the distance introduced in this paper does not satisfy all the properties that the class ofm athem atical ob jects usually referred to as distances do satisfy. For exam ple, the equivalence $D(x ; y)=0, x=y$ becom es, for the distance in eq. 8 , an im plication in only one direction, i.e., while it is true that $\left.V_{1}=V_{2}\right) d\left(V_{1} ; V_{2}\right)=0$, the reciprocal is false in general, since, for exam ple, if $V_{2}=B V_{1}+A$, with $B$ and $A$ non-zero constants, then $d\left(V_{1} ; V_{2}\right)=0$ when, clearly, the tw 0 instances are not equal. A nother property of the $m$ athem atical distances that is not ful led by $d$ is the one of sym $m$ etry, i.e., that $D(x ; y)=D(y ; x)$. If we denote all the quantities calculated when going from $V_{1}$ to $V_{2}$ by subscripting them w ith the label 12 and the ones corresponding to the opposite process w ith 21, we have that:

Therefore, if the equality $d\left(V_{1} ; V_{2}\right)=d\left(V_{2} ; V_{1}\right)$ is to be hold for every set ofconform ations $f q_{i} g_{i=1}^{n}$, onem ust require that $b_{12}=b_{21}=1$ and $a_{12}=a_{21}$. These tw o relations im pose com plicated conditions over the values of $f V_{1}\left(q_{i}\right) g_{i=1}^{n}$ and $\mathrm{fV}_{2}\left(g_{i}\right) g_{i=1}^{n}$ which are not generally ful lled. The origin of this lack of sym $m$ etry is com pletely consistent $w$ th the assum ptions $m$ ade about the random character of the tw o instances of the potentialenergy to be com pared, nam ely, the hypothesis of zero variance of $V_{1}$, which places the two potentials on a different footing. A m ore general distance $m$ ay be de ned (J.L. A lonso and P. Echenique, in preparation) that takes into account a possible indeterm ination in the $m$ easure of $V_{1}$ and that places the tw o potentials on the sam $e$ footing. H ow ever, som e rem arksm ust bem ade about this. In the rst place, this asym $m$ etry in the role played by each of the potential-energy instances is totally justi ed in the cases forw hich the situation intended to bem odeled is actually asym $m$ etric; for exam ple, if one's aim is to calculate the distance betw een a potential $V_{1}$ and an approxim ation $V_{2}$, where $V_{1} m$ ay be considered either ex-

[^5]act (e.g., quantum mechanical) orm uch $m$ ore accurate than $V_{2}$. In such a case, the assum ption of zero variance for $V_{1}$ and the di erence in the roles played by both potentials is intrinsic to the situation studied. A s a second rem ark, it $m$ ust be stressed that the distanœ herein de ned was never intended to be a $m$ athem atical distance, although som $e$ of the properties dem anded to these ob jects are satisfactory and fairly intuitive. The meaning of the distance $d$ is encoded in the statistical statem ents derived from its value and the nam e distance $m$ ust be used in a m ore relaxed $m$ anner than the one traditionally found in $m$ athem atics. F inally, it $m$ ust be pointed out that there is a situation in which the symm etry of the distance de ned in this work holds, nam ely, the situation in which $\mathrm{b}:=\mathrm{b}_{12}=1$ and $\mathrm{n}!1$. W hen the num ber of conform ations $n$ is very large, the statistical estim ators $b$ and a of the slope and the $y\left\{\right.$ intercept of the linear relation betw een $V_{1}$ and $V_{2}$ tend to the ideal values (see footnote 5) and, in these conditions, the rem aining requirem ents needed to satisfy symmetry are also ful lled, i.e., one has that $\mathrm{l}_{1}=1, \mathrm{a}_{12}=\mathrm{a}_{21}$ and, consequently, $\mathrm{d}\left(\mathrm{V}_{1} ; \mathrm{V}_{2}\right)=\mathrm{d}\left(\mathrm{V}_{2} ; \mathrm{V}_{1}\right)^{10}$. This fact is relevant since there are $m$ any situations typically found in which $b:=b_{12}$, 1 , nam ely, those in which $V_{1}$ and $V_{2}$ are proxim ate. $T$ his is the case if one $w$ ants to assess the robustness of a potentialenergy function (a slight change in the param eters does not lead to a com pletely di erent energy) or if the approxim ation perform ed is sm all. $T$ he two applications of the distance $d$ to a particular potential in sec. 3 are carried out in cases for which this proxim ity is achieved and the sym m etry expected has been checked num erically.

## 3 A pplication

$M$ ost of the nely tuned biom olecular events occur in a com plex environm ent of unique characteristics: liquid water. Therefore, if one aim s to correctly describe the crucial processes associated w ith proteins, DNA and RNA in living beings, a su ciently accurate $m$ odeling of water\{water and water\{solute interactions $m$ ust be im plem ented. H ow ever, accuracy is not the only criterium to be followed when designing a solvation $m$ odel. $N$ um ericalcom plexity of the m ethods m ust be also taken into account, as com putational power is alw ays a lim iting resource. A com prom ise between these two com peting factors m ust be reached and precision $m$ ay be traded for velocity, even if the understanding of the problem was com plete and a great accuracy could be achieved.

Particularly, in the study of the protein folding problem, the search for the native state takes place in an astronom ically large conform ational space, as

[^6]
$F$ ig. 3. D ielectric $m$ odel of the protein. A tom ic charges $q_{i}$ are punctual and located at nuclei. Space is divided in tw o disjoint regions: the m acrom olecule (in gray), w ith low dielectric constant P and the water (in white), w ith high dielectric constant w. T he surface of separation betw een the tw o m edia is constructed as described in the text.
early realized by Cyrus Levinthal in 1969 [18]. C onsequently, the intemal energy of the system, which inchudes the water molecules and the protein, $m$ ust be calculated a large num ber of tim es and the num erical com plexity of the $m$ ethod chosen to account for the in uence of water $m$ ust be as low as allowed by the accuracy required to solve the problem .

D espite being regarded as one of the m ost accurate im plem entations of solvent in uence, explicit $w$ aterm odels are presently too com putationally dem anding, allow ing only short sim ulations of peptides with a sm all num ber of residues to be perform ed. A nother popular option is to use continuum models based on Poisson ( PE ) or Poisson $\{\mathrm{Boltrm}$ ann ( PBE ) equations $[5,6,7,8]$, which are orders of $m$ agnitude faster than explicit solvent $m$ odels, to account for the electrostatic part of the free energy of solvation $[4,5]$. T hen, the nonelectrostatic part, which arises from the rst layer of water m olecules surrounding the solute and from the creation of the cavity, could be added in $m$ any ways, $m$ ost of which are related to the Solvent A ccessible Surface A rea (SA SA ) [19].

H ow ever, it is worth stressing that only the total free energy of solvation is them odinam ically de ned and experim entally m easurable. C onsequently, any partitioning of it is necessarily arbitrary and the free param eters contained in these continuum models (such as the dielectric constant $p$ of the protein,
the dielectric constant w of the aqueous m edium (see footnote 2), and the position of the surface that separates both regions (see g. 3)), m ust be $t$ prior to use in order to agree w ith experim ent or w th $m$ ore accurate $m$ ethods.

In this section, the dielectric constants are set to their standard values, $\mathrm{p}=1$ and $w=80$, and the characteristics of the surface of separation arem odi ed. Rigorously speaking, one would need an in nite number of param eters to com pletely specify this surface. H ow ever, it is used herein a restricted subset of all the possible surfaces, nam ely, those that can be obtained by rolling a sphere of radius $\mathrm{R}_{\mathrm{w}}$ on the outer side of the surface generated by adding $\mathrm{R}_{+}$ to the $V$ an der $W$ aals radii ${ }^{11}$ of each atom (see g.3). The volume that the rolling sphere does not intersect is considered to belong to the protein region. Typical values assigned to $R_{W}$ and $R_{+}$in the literature are [9,20]:
(1) $R_{W}=0: 0 \mathrm{~A}$ and $\mathrm{R}_{+}=0: 0 \mathrm{~A}$, producing the V an der W aals Surface
(2) $R_{W}=1: 4 \mathrm{~A}$ and $R_{+}=0: 0 \mathrm{~A}$, producing the $M$ olecular Surface
(3) $R_{W}=0: 0 \mathrm{~A}$ and $R_{+}=1: 4 \mathrm{~A}$, producing the Solvent A coessible Surface

These three surfaces are custom arily used as the separation between the two dielectric $m$ edia when the Poisson energy is calculated. H ow ever, it could be the case that a sm allchange in the param eters $R_{W}$ and $R_{+}$signi cantly alters the properties of this particular energy landscape. In such a situation, the choice of the surface w ould be crucial to the behaviour of the system. T herefore, the robustness of the $P$ oisson energy to changes in $R_{W}$ and $R_{+} m$ ust be assessed.

To accom plish this, we study a particular system : the de novo designed protein known as Tnp \{C age [21] (PDB code 1L2Y). TheCHARMM moleculardynam ics program [10,11] was used as a conform ation generator. From the native conform ation stored in the Protein D ata Bank [22] a 10 ps heating dynam ics ${ }^{12}$, from $\mathrm{T}=0 \mathrm{~K}$ to three di erent tem peratures, $\mathrm{T}=500 \mathrm{~K}, \mathrm{~T}=750 \mathrm{~K}$ and $T=1000 \mathrm{~K}$, was perform ed on the system. T his was repeated 50 tim es froreach naltem perature $w$ ith a di erent seed for the random numbers generator each tim e. The overall result of the process was the production of a set of 150 di erent conform ations of the protein, 50 of which are close to native, 50 partially unfolded and 50 com pletely unfolded (see g. 4). It is worth rem arking that the short time in which the system was heated (10 ps) and the fact that there $w$ as no equilibration after this process cause the naltem peratures

[^7]
$F$ ig. 4. E xam ple conform ations of the studied $T \mathrm{mp}$ \{C age protein. The native structure, taken from the $P$ rotein D ata $B$ ank is show $n$ on the upper left comer. From left to right and from top to bottom, three particular conform ations arbitrarily chosen from three di erent sets are depicted in order of decreasing sim ilarity to the folded protein. The average radii of gyration in each set $h \mathrm{R}_{\mathrm{G}}$ i and the one of the native structure are also presented.
( 500,750 and 1000 K ) to be only labels for the three aforem entioned sets of conform ations. They are, by no $m$ eans, the them odynam ical tem peratures of any equilibrium state from which the structures are taken. This three sets of conform ations are only $m$ eant to sam ple the representative regions of the phase space. In g.4, one arbitrarily chosen structure from each set is show $n$ together w ith the native conform ation. The average radius of gyration $h R_{G}$ i of each set, depicted in the sam e gure, $m$ ust be com pared to the radius of gyration of the native state.

U sing the nite di erences APBS program [24], the Poisson \{based electrostatic part of the solvation energy was num erically investigated in these conform ations. To calculate this quantity, one $m$ ust solve the Poisson equation tw ice. F irst, the energy of the system is com puted assum ing that a dielectric w ith $=\mathrm{p}$ lls the whole space. Second, one calculates the energy of the system w ith the dielectric geom etry shown in g.3.F inally, the rst quantity is substracted from the second to yield the solvation energy.

In order to test the reliability of the program and as an application of the rst possible use, described in section 1, of the distance de ned in this paper, the sensitivity of the Poisson energies to changes in the size of the grid $L$ used to solve the di erential equation was studied. For algorithm ic reasons, the allowed values for $L$ in APBS $m$ ust be of the form $L_{n}=32 n+1$, with n a positive integer. C onsequently, the Poisson solvation energy of each of the 150 conform ations of the protein was calculated ${ }^{13}$ w th $L=33, L=65$,

[^8]

Fig. 5. D istance betw een instances of the Poisson solvation energy with di erent grid sizes. The y $\{$ axis corresponds to the distance $d$ m easured in units of T ( w ith $\mathrm{T}=300 \mathrm{~K}$ ) and the scale is logarithm ic. E ach point represents the com parison of the energies calculated $w$ ith a sm aller grid size $L_{n}$ to those calculated $w$ ith a larger one $L_{n+1}$. Results for di erent values of $R_{+}$are show $n$. The value of $R_{W}$ is set to 1.4 A .
$L=97$ and $L=129$. All the measures were repeated for di erent values of $R_{+}$, ( $0.0,2.5$ and 5.0 A ) and $R_{W}$ was xed to 1.4 A . Then, for each $R_{+}$, ie. w ithout changing the param eters, the distance (see eq. 8) betw een the energies calculated w ith a grid size $L_{n}$ (playing the role of $V_{1}$ ) and the ones calculated $w$ ith $L_{n+1}$ (playing the role of $V_{2}$ ) was $m$ easured. The results are depicted in g. 5.

Two conclusions m ay be drawn from these data. O ne one hand, as the size of the grid $L$ increases, the distance d dim ishes. This is consistent w ith the expectation that, when the accuracy of an approxim ation augm ents, the differences betw een an exact potential energy and its approxim ated countenpart tend to disappear. O $n$ the other hand, one sees that, for values of $L$ betw een 97 and 129, the algorithm im plem ented in APBS has practically converged; in the sense that, for the worst case (nam ely, the one w ith $R_{+}=0: 0 \mathrm{~A}$ ), the distance betw een the energies calculated with $L=97$ and $L=129$ is of the order of the them al noise.

Two rem arks must be made about this last fact. $F$ irst, the situation with $R_{+}=0: 0$ A being the worst is easily understood if one realizes that the discontinuity of the electric eld in the surface of separation is larger if the latter is closer to the charges. T hus, a greater sensitivity to details is expected in this case. Second, it m ust be stressed that the distances depicted in 9.5 place a low er bound in the distances to be considered m eaningfiulw hen evaluating the
charges' grid m apping ag spl2 (cubic B \{spline discretization) and surface sm oothing ag smol (sim ple harm onic averaging) were used in all the calculations.

Fig. 6. D istance between instances of the Poisson solvation energy corresponding to di erent values of the free param eters. The y \{axis corresponds to the distance d measured in units of RT (w ith $T=300 \mathrm{~K}$ ) and the scale is logarithm ic. Each point represents the com parison of the energies calculated with the value of the param eters in its $x$ coordinate and the one calculated w th the inm ediately greater value (see text). The graph ic on the left show s the results obtained when $R_{+}$is held xed and $R_{W}$ is varied. $W$ hen $R_{W}$ is kept constant and $R_{+}$is varied, the $m$ easured distance $d$ is the one depicted in the graphic on the right.
robustness of the P oisson energy. For exam ple , if the param eter $\mathrm{R}_{\mathrm{W}}$ is slightly changed (keeping $R_{+}$xed to, say, 0.0A) any distance obtained, using a grid size of 97 or 129, that is below RT (see g.5) could not be associated to the lack of robustness of the $P$ oisson solvation energy in that particular region of the param eter space, since it $m$ ay be due to num erical inaccuracies of the algorithm .
$H$ aving this in $m$ ind, let us $x$ the grid size to 97 or 129 depending on the conform ation ${ }^{14}$ and evaluate the sensitivity of Poisson solvation energy to changes in the param eters $R_{W}$ and $R_{+}$that de ne the surface of separation, as an exam ple of the application of the distance $d$ to the second use proposed in section $1 . T$ his is done in the particular region of the param eter space which is typically explored in the literature: for $\mathrm{R}_{\mathrm{w}}$, the values $0.1,0.7,1.4$ (the Van der $W$ aals radius of a water molecule) and 2.8 A ; for $R_{+}$, the values from 0.0 to 5.0 A in steps of $0.5 \mathrm{~A} . \mathrm{W}$ hen $\mathrm{R}_{+}$is kept constant and $\mathrm{R}_{\mathrm{W}}$ is varied, the results on the left part of $g .6$ are obtained (only a few di erent values of $R_{+}$are depicted). $W$ hen, in tum, $R_{W}$ is held xed and $R_{+}$is varied, one obtains the results show $n$ on the right side of the same gure. In this second case, only the graphic corresponding to $R_{W}=1: 4 \mathrm{~A}$ is depicted, as the results for di erent values of $R_{W}$ are practically identical. As in $g .5$, each point corresponds to the distance between the instances of the P oisson energy with the i\{th value of the varying param eter and the one with the inm ediately

[^9]greater (i+1) \{th value. O f course, if two instances $w$ th very distant values of the param eters are com pared, the $m$ easured distance is $m$ uch larger than the values depicted in $9.6 . H$ ow ever, this is not relevant to assess the robustness, since only the distance betw een instances corresponding to slightly di erent param eters $m$ ust be $s m$ all in order to render a $t$ signi cant.

From the data shown in g. 6, one may extract som e relevant conclusions. $F$ irst, the two situations depicted are di erent in an im portant sense: while the robustness increases (d decreases) as onem oves tow ards larger values ofR ${ }_{+}$ holding $R_{W}$ constant, it does not change signi cantly in the opposite situation (ie. increasing $R_{W}$ w ith $x e d R_{+}$). The sam e behaviour $m$ ay be inferred from the fact that, on the left side of $g .6$, graphics corresponding to di erent values of $R_{+}$are found at di erent heigths, whereas, on the right side, the data $w$ ith di erent values of $R_{W}$ produce alm ost identical results (this is not shown for the sake of visual com fort). T he second im portant fact that m ust be pointed out is that, in agreem ent w ith what one would expect, the robustness of the P oisson solvation energy is $m$ inim um when the surface of separation is placed close to the molecule (i.e., sm all values of $R_{+}$). In the left graphic of $g .6$, one sees that, when $R_{+}$is of the size of the water molecule radius (1.4 A), the distance betw een instances of the potential energy produced by a sm all change in $\mathrm{R}_{\mathrm{W}}$ approxim ately reaches the largest num erical indeterm ination in $g .5$ and, consequently, the Poisson energy may be considered robust to such a change. In the right part of $g .6$, one nds that an equivalent level of robustness is only achieved at values of $R_{+}$around 3.0 A if $R_{W}$ is held xed and what is changed is $\mathrm{R}_{+}$.

To sum $m$ arize, one $m$ ay conclude that the robustness of the P oisson \{based electrostatic part of the solvation energy steadily increases when the surface that separates the tw o dielectric $m$ edia is $m$ oved further aw ay from the $m$ acrom olecular solute. T he largest value of the distance $d$ is of the order of 10R T when the surface of separation is placed on the $M$ olecular or $V$ an der $W$ aals Surface ( $\left.R_{+}=0: 0 \mathrm{~A}\right)$ and the sensitivity to param eter changes approxim ately reaches the num erical indeterm ination of the algorithm used when the surface is one layer of $w$ ater $m$ olecules aw ay from the protein.

## 4 C onclusions

W hen calculating a term or the totality of a potential energy function in com plex system $s$, two situations are often faced: the necessity to evaluate the relative accuracy of an approxim ation or an algorithm respect to a m ore precise calculation and the need to assess the signi cance of a free param eters'
t. H erein, a distance betw een two di erent instances of the sam e potential energy function has been devised, which m ay be used to answ er the two pre-
ceding questions by $m$ aking $m$ eaningful statistical statem ents about the way in which energy di erences are modi ed when changing the algorithm or the param eters.

In section 3, a practical exam ple of the two cases is given by studying the sensitivity of the Poisson \{based electrostatic part of the solvation energy to such changes. This exam ple is useful, on one hand, to show that the distance behaves consistently in a real situation and, on the other hand, to estim ate the robustness of the P oisson energy when sm all changes are perform ed on the ideal surface that separates the protein cavity from the aqueous media. It is show $n$ that this robustness, both to changes in $R_{W}$ and in $R_{+}$, increases as the surface is $m$ oved further aw ay from the $m$ acrom olecule, being $d$ 10R $T$ when the surface is placed at zero distance from the $V$ an der $W$ aals volum e of the protein and reaching the num erical indeterm ination at a distance of around a layer of water m olecules ( 3:0 A).

    ${ }^{12}$ The c27b4 version of the CHARMM program was used. Them olecular dynam ics were perform ed using the Leap Frog algorithm therein im plem ented and the param22 param eter set, which is optim ized for protein s and nucleic acids. T he w ater has been taken into account im plicitly $w$ ith the $D$ om iny et al. [23] version of the $G$ eneralized Bom $M$ odelbuilt into the program.

[^8]:    ${ }^{13}$ Boundary conditions ag mdh (non\{interacting spheres with a point charges),

[^9]:    ${ }^{14} \mathrm{~W}$ hat was actually done was to choose $\mathrm{L}=97$ or $\mathrm{L}=129$ in order to keep the length of the grid cell below 0.5 A in each dim ension. In practice, this led to using $\mathrm{L}=97$ for the m ost com pact and globular conform ations and $\mathrm{L}=129$ for the m ost extended ones.
