#### Abstract

W e apply several quantization schem es to sim ple versions of the Chinos gam e. C lassically, for tw o players w ith one coin each, there is a sym m etric stable strategy that allow s each player to $w$ in half of the tim es on average. A partial quantization of the gam e (sem iclassical) allow s us to nd a w inning strategy for the second player, but it is unstable w r.t. the classical strategy. H ow ever, in a fully quantum version of the gam ewe nd a winning strategy for the rst player that is optim al: the sym $m$ etric classical situation is broken at the quantum level.

PACS num bers: 03.67.-a, 03.67 Lx

In a typical scene at a Spanish restaurant, a sm all group of com panions-at-table gather at the bar extending their arm s, each with their clenched hands holding a few coins hidden inside. They are gambling for the after-lunch round of co ees. O ne after another they tell a num ber, then open their hands show ing their coins one another and count them all. Ofently, one of the pals sm ile $m$ eaning that $s / h e ~ g u e s s e d ~ t h e ~ c o r r e c t ~ t o t a l ~ n u m ~-~$ ber of coins. A fter a given num ber of plays, the player scoring the w orst pays for allco ees. This gam bling gam e is know $n$ as the $C$ hinos gam $e$ and has been a traditional way in Spain to decide who is in charge for the co ees' check [1].

Interestingly enough, this simple-m inded guessing gam e exhibits a rich variety of pattems w ith com plex behaviour that has been used to m odel strategic behaviour in som e socialand econom ic problem s, like nancialm arkets and inform ation transm ission 17]. This is an exam ple of non-cooperative gam $e$ for each player seeks to $m$ axim ize her/his chances of guessing correctly, and at the sam e tim e to m inim ize the possibilities of her/his opponents.

Recently, a new eld for gam e theory has em erged in the form of quantum gam es w th the goal of taking advantage of quantum e ects to attain a winning edge $\sqrt[3]{ }$, [4] [5]. The blending of quantum $m$ echanics $w$ th gam $e$ theory opens novel strategies based in exploiting the peculiarities of quantum behaviour, and it has already estim ulated a num ber of new ideas, e.g., in the $P$ risioners' D ilem m a there exists a quantum strategy that allow s both players to escape the dilem $m$ a 4 .

In this letter our aim is tw ofold: rstly, to de ne quantum versions of the $C$ hinos gam e such that they reduce to the classicalgam e as a lim iting case. Secondly, to analyse the new quantum versions in order to nd how the classical strategies behave under quantum e ects, and if there exists new quantum winning strategies w ithout classical analogue.
$C$ lassical $C$ hinos $G$ ame. In the classical form ulation, a num ber $N_{p}$ of players enter the gam $e$, each having access to $\mathrm{N}_{\mathrm{c}}$ coins that they draw and hide in their hands at each round of the gam $e$. N ext, each player $m$ akes a guess about the total num ber of coins held at that round, w ith the constraint that no player can repeat the num ber guessed by the previous players. Thus, the outcom e of a given round $m$ ay be either that one player w ins or failure for everyone. As a rem ark, the heads and tails of the coins play no role in the Chinos gam $e$, so that they can be sim ply regarded as pebbles: only their num ber count.

Let $D:=f 0 ; 1 ;::: ; \mathrm{N}_{\mathrm{c}} \mathrm{g}$ be the space of draws and $\mathrm{G}:=\mathrm{f0} ; 1 ;::: ; \mathrm{N}_{\mathrm{p}} \mathrm{N}_{\mathrm{c}} \mathrm{g}$ be the space of guesses for the rst player. Each players' m ovem ent has two parts: 1/ draw ing coins; 2/ guessing the totalnum ber of coins altogether. Let us denote by $M:=(d ; g)$ one of these $m$ ove$m$ ents, w th d 2 D and g 2 G . The space of $m$ ovem ents is $M:=\mathrm{G}$ for the rst player. N ext players have a reduced guess space $G_{(i)}^{0}:=G \quad{\left.f d_{(1)} ;:: ; d_{(i)} 1\right)}^{0} ; i=$ 2; ::;; $\mathrm{N}_{\mathrm{p}}$. A possible strategy S is an ordered sequence ofm ovem ents $S:=\left(M_{1} ; M_{2} ;:: ; \mathrm{M}_{r}\right)$ selected $w$ ith som e criteria or random $l y$, and played during the $r$ rounds that the whole gam e takes.

We shall denote by CCG( $\left.\mathbb{N}_{\mathrm{p}} ; \mathrm{N}_{\mathrm{C}}\right)$ a classical Chinos gam eof $N_{p}$ players and $N_{c}$ coins. The exhaustive analysis ofsuch a generic gam etums out to be too com plicated [2], thus we shall concentrate on the case of only $N_{p}=2$ players for which we have the follow ing result:
$1^{\text {st }}$ Result. Let us denote the classical strategies for
 $T$ hen, the best strategy for player 1 is to choose $m$ ove$m$ ents $M_{(1) ; j i j}=1 ; 2 ;::: ; r$ with $d_{(1) ; j}$ random ly distributed and $g_{(1) ; j}=N_{c} ; 8 j$, while the best strategy for player 2 is to choose draw $\mathrm{Sd}_{(2) \text {; }}$ at random. For r large enough, the result of the gam $e$ is even.

Proof. Since the Chinos game is a non-cooperative gam e, in this result we are assum ing that one of the m ain goals of player 1 is not to transm it any inform a-
tion to player 2 about her/his values $\mathrm{d}_{(1) ; j}$. This can be achieved by choosing $g_{(1) ; j}=N_{c}$ irrespective of the num ber that $s / h e$ draw $s$. M oreover, players soon realize that as they cannot know in advance her/his opponent strategy, the best strategy they can choose is to pick $d_{(i) ; j} ; i=1 ; 2 ; 8 j$ at random.$N$ ow, let us call $p_{1}$ the probability that player 1 guesses correctly the total sum they are after, nam ely, $a_{j}:=d_{(1) ; j}+d_{(2) ; j}$, and sim ilarly for $p_{2}$. T he quantities each player is interested in $\mathrm{P}^{m}$ axim izing are the norm alized probabilities $P_{i}:=p_{i}=\quad{ }_{i=1 ; 2} p_{i}$. Thus, under these circum stances, the probability that the second player guesses the correct sum is

$$
\begin{equation*}
\mathrm{p}_{2}=\frac{1 \quad \mathrm{p}_{1}}{\mathrm{~N}_{\mathrm{c}}}: \tag{1}
\end{equation*}
$$

Then, the quantity player 2 w ants to optim ize is

$$
\begin{equation*}
\mathrm{P}_{2}=\frac{1 \mathrm{p}_{1}}{1+\mathrm{p}_{1}\left(\mathbb{N}_{\mathrm{c}} 1\right)} \tag{2}
\end{equation*}
$$

$w$ hich is a decreasing function of $p_{1}$, so that player 2 is interested in reducing $p_{1}$ as m uch as possible. H ow ever, player 1 can alw ays resort to $m$ ake random guesses about the num ber of coins draw $n$ by player 2 . This am ounts to a low est bound on $p_{1}$ given by $p_{1 ;<}:=1=\left(\mathbb{N}_{c}+1\right)$. Therefore, player 2 should draw coins at random so that $p_{1}$ cannot exceed $\mathrm{p}_{1}$; and we end up w th an even stuation given by 6]

$$
\begin{equation*}
P_{1}=P_{2}=\frac{1}{2}: \tag{3}
\end{equation*}
$$

W em ay view this result as a sort of \classical sym metry" between players 1 and 2:

$$
\begin{equation*}
\text { P layer } 1 \quad!\quad P \text { layer 2; } \tag{4}
\end{equation*}
$$

in the sense that there is now way to untight the result of the game if both playens play at random. O ur goal is to de ne quantum extensions of the Chinos gam e to see if this sym $m$ etry can be broken at the quantum level. W e shalluse this classical result as a guide to analyse the behaviour of classical strategies w hen we enter the realm of the quantum extensions of the gam $e$.
Sem iclassical Chinos $G$ ame. A rst attem pt at quantizing the $C$ hinos gam $e$ is to $m$ ake a quantum extension of the space of draw $s D_{q}$ while leaving the space of guesses G classical. We term this case sem iclassical for obvious reasons and denote by $\operatorname{SCG}\left(\mathbb{N}_{p} ; \mathrm{N}_{\mathrm{C}}\right)$ a sem iclassical Chinos gam e. The natural choice for $\mathrm{D}_{\mathrm{q}}$ is to replace coins by quantum coins or qubits. Likew ise, a quantum tw o-level system is represented by a spin $\frac{1}{2}$ particle w ith states j"i; j\#i representing heads and tails, respectively. H owever, we nd that spins are not appropriate in the C hinos gam e since only the presence or absence of coins in players' hands $m$ atters. $H$ ence, a m ore suitable way
of representing qubits is to use a boson system de ned by bosonic creation/annihilation operators by ;b obeying canonical commutation relations (CCR) $\left[b ; b^{y}\right]=1$ and acting on the bospnic vacuum $j 0 i$ in the standard fashion: $b j 0 i=0 ; b^{y} j n i=p \overline{n+1} j+1 i, w$ ith $j 1:=\left(b^{y}\right)^{n} j 0 i=\overline{n!}$.

For simplicity, we shall consider rst the case in which each quantum player has only one coin, nam ely, $S C G\left(\mathbb{N}_{p} ; 1\right)$.

To each player $i=1 ; 2 ;:: ; \mathrm{N}_{\mathrm{p}}$ we shall assign a set of operators $0(i ; i)$ param eterized by the two angles characterizing a qubit state in the B loch sphere. T hus, we introduce

$$
O_{i}(;)=\cos \frac{1}{2}{ }_{i}+e^{i}{ }^{i} \sin \frac{1}{2}{ }_{i} b^{y} ; 2_{i} ; 2_{i}[0 ; 2): \text { (5) }
$$

These operators represent the quantum draw space $\mathrm{D}_{\mathrm{q}}$. At a given round $j$ of the gam $e$, each player selects one possible operator $O_{i}(;)$ and at the end of the draw ing process, we represent the situation of having all players' hands together by the follow ing joint quantum state
where N is a norm alization constant and $\mathrm{C}_{\mathrm{n}}$ expansion coe cients. This state faithfully represents the fact that what really counts is to guess the total sum $a_{j}=\underset{i=1}{N_{p}} d_{(i) ; j} 2 \mathrm{G}$, no $m$ atter $w$ hat the partial contributions $\mathrm{d}_{(\mathrm{i}) \text {; }}$ of each player are. M oreover, the quantum e ects are clearly apparent since $w$ hen the state $j_{S_{G}}^{\left(N_{\mathrm{p}} ; 1\right)}{ }_{i}$ is expanded in states ji; 2 G , each coe cient $\mathrm{c}_{\mathrm{n}}$ receives contributions from each player that cannot be factorized out. Then, w ith (G) we can com pute the probability $p(n)$ that any player obtains the value $g=n$ after a m easurem ent, nam ely,

$$
\begin{equation*}
p(n):=\ln j \underset{S C G}{\left(N_{p} ; 1\right)} i f=c_{n}^{2} n! \tag{7}
\end{equation*}
$$

$W$ ith the present quantization schem e we have an innitely $m$ any num ber of possible draw $s$. In practioe, it is a reasonable assum ption to reduce the possible operator choices to a nite restricted set. To be concrete, let us consider the case of $N_{p}=2$ players SCG $(2 ; 1)$ and we select from (6) the follow ing reduced operator set

$$
\begin{align*}
& O_{1}=I ; O_{2}=\frac{1}{P_{\overline{2}}}\left(I+b^{y}\right) \\
& O_{3}=\frac{1}{\frac{1}{2}}\left(I \quad b^{y}\right) ; O_{4}:=b^{y}: \tag{8}
\end{align*}
$$

N otioe that operators $\mathrm{O}_{1}$ and $\mathrm{O}_{4}$ represent the classical draw s of 0 and 1 , respectively, while $\mathrm{O}_{2}$ and $\mathrm{O}_{3}$ represent novelquantum superpositions of the classicaldraw s. These conditions represent a generic situation to analyse quantum e ects in the Chinos gam $e$ and we nd the follow ing result:

|  | $\mathrm{O}_{1}^{(1)}$ | $\mathrm{O}_{2}^{(1)}$ | $\mathrm{O}_{3}^{(1)}$ | $\mathrm{O}_{4}^{(1)}$ |
| :---: | :---: | :---: | :---: | :---: |
| ${ }_{1}^{(2)}$ | $\mathrm{p}(0)=1$ | $\mathrm{p}(0)=\frac{1}{2}$ | $\mathrm{p}(0)=\frac{1}{2}$ | $\mathrm{p}(0)=0$ |
|  | $\mathrm{p}(1)=0$ | $\mathrm{p}(1)=\frac{1}{2}$ | $\mathrm{p}(1)=\frac{1}{2}$ | $\mathrm{p}(1)=1$ |
|  | $\mathrm{p}(2)=0$ | $\mathrm{p}(2)=0$ | $\mathrm{p}(2)=0$ | $\mathrm{p}(2)=0$ |
| $\mathrm{O}_{2}^{(2)}$ | $\mathrm{p}(0)=\frac{1}{2}$ | $\mathrm{p}(0)=\frac{1}{7}$ | $\mathrm{p}(0)=\frac{1}{3}$ | $\mathrm{p}(0)=0$ |
|  | $\mathrm{p}(1)=\frac{1}{2}$ | $\mathrm{p}(1)=\frac{4}{7}$ | $\mathrm{p}(1)=0$ | $\mathrm{p}(1)=\frac{1}{3}$ |
|  | $\mathrm{p}(2)=0$ | $\mathrm{p}(2)=\frac{2}{7}$ | $\mathrm{p}(2)=\frac{2}{3}$ | $\mathrm{p}(2)=\frac{2}{3}$ |
| $\mathrm{O}_{3}^{(2)}$ | $\mathrm{p}(0)=\frac{1}{2}$ | $\mathrm{p}(0)=\frac{1}{3}$ | $\mathrm{p}(0)=\frac{1}{7}$ | $\mathrm{p}(0)=0$ |
|  | $\mathrm{p}(1)=\frac{1}{2}$ | $\mathrm{p}(1)=0$ | $\mathrm{p}(1)=\frac{4}{7}$ | $\mathrm{p}(1)=\frac{1}{3}$ |
|  | $\mathrm{p}(2)=0$ | $\mathrm{p}(2)=\frac{2}{3}$ | $\mathrm{p}(2)=\frac{2}{7}$ | $\mathrm{p}(2)=\frac{2}{3}$ |
| ${ }^{(2)}$ | $\mathrm{p}(0)=0$ | $\mathrm{p}(0)=0$ | $\mathrm{p}(0)=0$ | $\mathrm{p}(0)=0$ |
|  | $\mathrm{p}(1)=1$ | $\mathrm{p}(1)=\frac{1}{3}$ | $\mathrm{p}(1)=\frac{1}{3}$ | $\mathrm{p}(1)=0$ |
|  | $\mathrm{p}(2)=0$ | $\mathrm{p}(2)=\frac{2}{3}$ | $\mathrm{p}(2)=\frac{2}{3}$ | $\mathrm{p}(2)=1$ |

TAB LE I: P robabilities for the outcom es oftotalcoins 0,1 and 2 in a SCG $(2 ; 1)$ game. In the horizontal, the draw $s$ of player 1 and in the vertical, the draw sfor player 2 .
$2^{\text {nd }}$ Result. i) $T$ he strategy of draw ing random ly from (8) becom es a winning strategy for player 2. H ow ever, this strategy is unstable. ii) The classical strategy of draw ing random ly betw een $\mathrm{O}_{1}$ and $\mathrm{O}_{4}$ is a w inning strategy forboth players (evenness) and is stable.

P roof. T he analysis relies on Table $\ddagger$ show ing the probabilities of obtain ing 0,1 and 2 coins when player 1 draw s operator $\mathrm{O}_{\mathrm{i}_{1}}^{(1)}$ and player 2 draw $\mathrm{SO}_{\mathrm{i}_{2}}^{(2)}, i_{1} ; i_{2}=1 ; 2 ; 3 ; 4$, according to (G)-(G). i/ Let us assum $e$ that players 1 and 2 both know the classicalw inning strategy of CCG and decide to $m$ ake a straightforw ard generalization of it to the sem iclassicalcase SC G . T hen, player 2 decides to play random draw sam ong the four possible choioes in (8). In this situation, player 1 is left $w$ ith a set of probabilities of getting a num ber of coins 0,1 and 2 given by Table $\mathbb{1}$, which are computed from $\mathrm{Table} ⿴$ by tracing out (averaging) over player 2. H ence, if the second player plays at random, the best choice for player 1 is to guess 1 (or 0 ) if $\mathrm{s} /$ he draw $\mathrm{O}_{1}^{(1)}$, and 2 if $\mathrm{s} /$ he draw $\mathrm{O}_{2}^{(1)}, \mathrm{O}_{3}^{(1)}$ and $\mathrm{O}_{4}^{(1)}$. Thus, her/his total chances of $w$ inning are:

$$
\begin{equation*}
P_{1}=\frac{1}{4} \quad \frac{1}{2}+\frac{1}{2} \quad \frac{68}{168}+\frac{1}{4} \quad \frac{7}{12}=\frac{53}{112}<\frac{1}{2} \tag{9}
\end{equation*}
$$

$T$ herefore, the strategy of both players draw ing at random is no longer an even strategy in this case.
ii/ H ow ever, after a large num ber of rounds $r$, player 1 w ill realize that playing at random is a winning strategy for her/h is opponent and then s/he w ill seek to im prove it. To do this, s/hem ay resort to draw only the classical choices. T hen, from Table 4 , her/his chances ofw inning are

$$
\begin{equation*}
P_{1}=\frac{1}{2} \quad \frac{1}{2}+\frac{1}{2} \quad \frac{7}{12}=\frac{13}{24}>\frac{1}{2} \tag{10}
\end{equation*}
$$

$T$ his im plies that the strategy in i) is not stable. Likew ise, player 2 w ill not be happy w ith this new situation. $\mathrm{S} / \mathrm{he}$

| $\mathrm{O}_{1}^{(1)}$ | $\mathrm{O}_{2}^{(1)}$ | $\mathrm{O}_{3}^{(1)}$ | $\mathrm{O}_{4}^{(1)}$ |
| :---: | :---: | :---: | :---: |
| $\mathrm{hp}(0) i=\frac{1}{2}$ | $\mathrm{hp}(0) i=\frac{41}{168}$ | $\mathrm{hp}(0) i=\frac{41}{168}$ | $\mathrm{hp}(0) i=0$ |
| $\mathrm{hp}(1) i=\frac{1}{2}$ | $h p(1) i=\frac{59}{168}$ | $\mathrm{hp}(1) i=\frac{59}{1688}$ | hp (1) $i=\frac{5}{12}$ |
| $\mathrm{hp}(2) i=0$ | $h p(2) i=\frac{68}{168}$ | $\mathrm{hp}(2) i=\frac{68}{168}$ | $\mathrm{hp}(2) i=\frac{7}{12}$ |

TABLE II: A veraged probabilities of obtaining 0,1 , and 2 coins by player 1 in a SC G $(2 ; 1)$ gam e according to the draw $\mathrm{SO}_{\mathrm{i}} ; \mathrm{i}=1 ; 2 ; 3 ; 4 \mathrm{~s} /$ he m akes.
w illtry to $m$ atch player's 1 strategy by choosing the sam e purely classical strategy. This fully classical situation is represented by the boxes at the outer comers of Table t. Then we are led to $P_{1}=P_{2}=\frac{1}{2}$ as the stable best strategy as in 目).

This result m eans that ifplayer1 applys her/h is know ledge of the classical gam e naitvely by draw ing at random from the four choioes available, in the long run $s / h e w$ ill realize that player 2 gets a w inning edge.
$Q$ uantum Chinos $G$ am e. M otivated by the previous sem iclassicalanalysis, we propose a fully quantized version of the Chinos gam e by quantizing both the draw space $\mathrm{D}_{\mathrm{q}}$ and the guessing space $\mathrm{G}_{\mathrm{q}} . \mathrm{W}$ e shall de ne the quantum space of guesses $G_{q}$ by allow ing each player to $m$ ake a
 notm erely about the possible outcom es of the totalcoins. Thus, each player iw illm ake a guess j ii; $i=1 ; 2$;::; $N_{p}$ about what the actual joint quantum state they are dealing with. M oreover, we also extend quantum ly the classical constraint that the guess $g_{i}$ of player i cannot be the same as guesses $g_{j}$ for $i<j$. This is achieved by im posing that the guess a player i can $m$ ake is restricted to the subspace orthogonal to the space spanned by the guesses of the previous players, nam ely,

$$
\begin{equation*}
\mathrm{G}_{\mathrm{q} ; \mathrm{i}}:=\operatorname{spanfj}{ }_{1} \mathrm{i}_{i}::: ; j_{\text {i } 1} \text { ig }^{?}: \tag{11}
\end{equation*}
$$

$W$ ith these new rules, we need to de ne a new function payo : the gain for player $i$ is

$$
\begin{equation*}
f_{i}:=\ln _{i j}{ }_{\mathrm{SCG}}^{\left(\mathbb{N}_{\mathrm{p} ; 1)}\right)} i f: \tag{12}
\end{equation*}
$$

This way of quantizing the space of guesses is rem iniscent of the theory of quantum algorithm $s$ [], and m ore speci cally, from quantum searching algorithm s 8], [9]. $T$ hat this fully quantum version of the $C$ hinos gam $e$ includes the classicalone is guaranteed since the latter appears as a particular case when the only allow ed guesses
 $\left.\mathrm{N}_{\mathrm{C}}=1.\right)$

For simplicity, we shall consider the quantum case $Q C G\left(N_{p} ; N_{C}\right)$ for two players and one coin each, and their quantum guesses com prise the nite set (8). W e nd the follow ing result:
$3^{\text {rd }}$ Result. In a quantum Chinos gam e CCG $(2 ; 1)$, the rst player has a stable winning strategy that allow s her/his to $w$ in $m$ ore than half of the tim es.

Proof. A system atic analysis in this case of 2 players w ith one coin each proceeds as follows. The space of draw sfor player 1 is $D_{q}$ given by the reduced set (G). $T$ hen, player 1 draw $\mathrm{O}_{\mathrm{i}_{1}}^{(1)} 2 \mathrm{D} \mathrm{q}$. The space of guesses
 player 1 m akes a quantum guess $\mathrm{g}_{\mathrm{q} ; 1}:=0_{j_{1}}^{(1)} \mathrm{O}_{\mathrm{k}_{1}}^{(1)} 2 \mathrm{G}_{\mathrm{q} ; 1}$. N ow entersplayer 2 w th a draw $\mathrm{O}_{\mathrm{i}_{2}}^{(2)} 2 \mathrm{D}$, and m aking a guess $g_{q ; 2}:=O_{j_{2}}^{(2)} \mathrm{O}_{\mathrm{k}_{2}}^{(2)}$ that in order to be eligligible, it has to be orthogonalto player's 1 guess 11). To characterize this orthogonality condition, it is convenient to introduce the follow ing 1616 m atrix

$$
\begin{align*}
& G_{\left(j_{1} ; k_{1}\right) ;\left(j_{2} ; k_{2}\right)}=\frac{h 0 j 0 O_{j_{1}}^{Y} O_{k_{1}}^{Y} O_{j_{2}} O_{k_{2}} j_{i} D_{j_{1} k_{1}}}{\overline{N_{j_{2} k_{2}}}} ;  \tag{13}\\
& N_{j k}:=h 0 j 0{ }_{j}^{Y} O_{k}-\mathrm{DO} i_{;}
\end{align*}
$$

which can be thought of as a metric on the quantum guess space. Thus, guess $g_{q ; 2}$ is adm issible for the given guess $g_{q ; 1} i G_{\left(j_{1} ; k_{1}\right) ;\left(j_{2} ; k_{2}\right)}=0$. Finally, for a pair of draw $s$, the actual joint state representing that round of the gam e is

$$
\begin{equation*}
j \underset{Q C G}{(2 ; 1)} i=N_{12}^{1=2} O_{i_{1}}^{(1)} O_{i_{2}}^{(2)} \mathrm{j} \mathrm{i}_{i} ; \tag{14}
\end{equation*}
$$

while the function payo $s f_{i} ; i=1 ; 2$ for each player can also be read o from the $m$ etric 13 as follow s

$$
\begin{align*}
& f_{1}=J_{\left(j_{1} ; k_{1}\right) ;\left(i_{1} ; i_{2}\right)} J^{2} ; \\
& f_{2}=j G\left(j_{2} ; k_{2}\right) ;\left(\text { i1 } 1 ; i_{2}\right) J^{2}: \tag{15}
\end{align*}
$$

T hen, once we have com puted the $m$ etric 13), it is possible to $m$ ake an exhaustive study of all the possibilities in this quantum Chinos gain and com pute each players' payo $s$ for each of those possibilities. W e have perform ed this analysis w ith the follow ing result: let us show that if player 1 m akes draw s w th equal probability am ong the choices $\mathrm{O}_{2}^{(1)}$ and $\mathrm{O}_{3}^{(1)}$ only (8), then $\mathrm{s} /$ he is halfw ay for a winning position. T he rest of the strategy is to set up the quantum guesses as follows. W hen player 1 draws $\mathrm{O}_{2}^{(1)}, \mathrm{s} /$ he decides to m ake alw ays the follow ing quantum guess

$$
\begin{equation*}
j_{1} i=N_{1}{ }^{1=2} O_{2}^{(1)} O_{2}^{(1)} j 0 i=P_{\overline{7}}^{1}\left(j 0 i+2 j 1+{ }^{p} \overline{2} 2 i\right) ; \tag{16}
\end{equation*}
$$

in which case, a possible guess for player 2 according to 11) would be

$$
\begin{equation*}
j_{2} i:=N_{2}{ }^{1=2} O_{3}^{(2)} O_{4}^{(2)}-\mathrm{Oi}=\mathrm{P}_{\frac{1}{3}}^{1}\left(\mathrm{lli} \quad \mathrm{P}_{2} \mathrm{Z} i\right): \tag{17}
\end{equation*}
$$

W hile if $\mathrm{s} /$ he draw $\mathrm{O}_{3}^{(1)}$, $\mathrm{s} /$ he decides to m ake alw ays the follow ing quantum guess

$$
\begin{equation*}
j_{1} i=N_{1}{ }^{1=2} O_{3}^{(1)} O_{3}^{(1)} j 0 i=P_{\overline{7}}^{1}\left(j 0 i \quad 2 j 1 i+{ }^{p} \overline{2} 2 \lambda i\right): \tag{18}
\end{equation*}
$$

N ow, let us analyse the case w hen player 1 draw $\mathrm{SO}_{2}^{(1)}$. $T$ hen, player 2 is left w th the four draw s in the set (G) and the correspoding joint nal states $j \underset{\mathrm{SCG}}{(2 ; 1)}$ i that we collet in Table $\mathbb{T}$. W hen the rst player draw $\mathrm{SO}_{3}{ }^{(1)}$, then we obtain a sim ilar table by exchanging $2 \$ 3$.
$>$ From Table we see that under these circum stances, it is clear that player 2 w ill avoid to m ake the classical draw so ${ }_{1}^{(2)}$ and $\mathrm{O}_{4}^{(2)}$, since they yield payo $\mathrm{s} \mathrm{f}_{1}=\frac{9}{14}>$ $\frac{1}{2}, f_{1}=\frac{16}{21}>\frac{1}{2}$ for the rst player. Thus, player 2 is led to play only the draw $\mathrm{SO}_{2}^{(2)}$ and $\mathrm{O}_{3}^{(2)}$ at random. H ow ever, even in this case, player 1 w ill have a winning edge on the average since the chances of $w$ inning for the rst player are

$$
\begin{equation*}
h f_{1} i=\frac{1}{2} \quad 1+\frac{1}{2} \quad \frac{1}{21}=\frac{11}{21}>\frac{1}{2}: \tag{19}
\end{equation*}
$$

| Q uantum guess |  | G ain for player 1 |
| :---: | :---: | :---: |
| $\mathrm{O}_{1}^{(2)}$ | $\frac{1}{\overline{2}}$ ( $\mathrm{j} 0 \mathrm{i}+\mathrm{j} 1 \mathrm{i}$ ) | $\mathrm{f}_{1}=\frac{9}{14}$ |

| $\mathrm{O}_{3}^{(2)}$ | ${ }^{1} \frac{1}{\overline{3}}-0 \mathrm{l}$ | $\mathrm{f}_{1}=\frac{1}{21}$ |
| $\mathrm{O}_{4}^{(2)}$ |  | $\mathrm{f}_{1}=\frac{16}{21}$ |

TABLE III: Q uantum guesses for player 2 when player 1 draw $\mathrm{O}_{2}^{(1)}$ (8), and the corresponding joint state 14) and gains for player 1 15).

C onclusions. In gam e theory, players strive for even the slightest advantage that w ould tilt a gam e's outcom e in their favor. W e have found that the chances ofw inning forplayer 1 arebettero on average than those ofher/his opponent. W e m ay interpret this result as the breaking of the sym $m$ etric classical situation (8) at the quantum level:

P layer $1 \neq P$ layer 2 :
(20)
$T$ his advantage of the rst player resem bles a sim ilar situation found in the $P Q$ quantum gam e团]. In the present case, how ever, the correlation betw een players in the nal result is dynam ically generated, i.e., it is a consequence of the player's choice, and it is not encoded in the initial state. In this respect, it also di ers from the quantum generalization of other sim ple gam es, like the prisoner's dilem $m$ a [4], or the $m$ inority gam e 10].
A cknow ledgm ents. W e acknow ledge nancial support from pro jects: P G C 96-0875, 07N / 0015/2001 and P B 980685.
[1] W e do not claim that the Chinos gam e originates from Spain, but the word chinos is a deform ation of chinas m eaning pebbles in Spanish.
