#### Abstract

W e propose a schem e for entangling tw o eld modes in tw o high-Q optical cavities. M aking use of a virtual two-photon process, our schem e ach ieves $m$ axim ally entangled states $w$ thout any real transitions of atom ic intemal states, hence it is im $m$ une to the atom ic decay. PACS num ber(s):03.67.Lx, 32.80.W r, 42.50.-p

E ntanglem ent is one of the $m$ ost characteristic features of quantum system $s$ and lies at the heart of the di erence betw een the quantum and classicalm ulti-particle world. It is the phenom enon that enables quantum inform ation processing and com puting [1]. Beyond these and other related applications, com plex entangled states, such as the GHZ triplets of particles [2] can be used for tests of quantum non-locality [3]. M oreover, the relaxation dynam ics of larger entangled states sheds light on the decoherence process and on the quantum -classicalboundary [4]. There are a lot of proposal devoted to the preparation of quantum entangled states, am ong them the idea forphoton dow n-conversion process [3], w ith trapped ions [5], for cavity quantum electrodynam ics [6], w ith m acroscopic ob jects [7] or for an optical bre [8] has been realized experim entally.

In the latter case, the entanglem ent results from the nonlinear interaction between the two modes in an optical bre. This is closely connected to the recent advance ofenhancing nonlinear coupling via electrom agnetically induced transparency (E IT) m echanism [9]. M easured value of the ${ }^{(3)}$ param eter are up to six order of $m$ agnitude larger than usual [10]. This has opened the door tow ard the application of this kind ofnonlinear process to quantum inform ation processing even for the very low photon-num ber case [11]. In fact, there are several proposals for exploiting huge $K$ err non-linearities to perform com putation and quantum teleportation $[12,13]$ or for quantum non-dem olition $m$ easurem ents [14]. A part from the $K$ errnonlinearity, the experim entalachievem ent of atom ic B ose E instein condensation (BEC) also provide us a chance to create $m$ any particle entanglem ent $w$ ith nonlinear interactions [15\{22]. A ll these show that the non-linear interaction betw een di erent quantum modes is a valuable resource for quantum inform ation processing.

In this paper, we present a new theoretical schem efor entangling two quantum $m$ odes in two high-Q optical cavities. Through a virtual two-photon process, an ef-
fective non-linear interaction betw een the tw o $m$ odes can be established. By $m$ aking use of the virtual tw o-photon process, our new protocol signi cantly reduces the e ect of atom ic spontaneous em ission during the entanglem ent preparation process.

O ur system consists of two optical cavities as in Ref. [23] and an atom system surrounded by the two optical cavities. The axis of the two cavities are perpendicular each to other, the intemal structure of the atom is depicted in Figure 1,

[^0]FIG.1. A 4-level atom interacting with two cavity quantum elds. B oth cavity elds are detuned from atom ic resonance by $=$ ! , and $=2 \quad!\mathrm{e}$.

The atom is assum ed to $m$ ake two-photon transitions of frequency ! e betw een the nondegenerate state jgiw ith energy $!_{\mathrm{g}}=0$ and the excited state jei. T he transitions are m ediated by two interm ediate degenerate levels $\ddot{\mu}_{1} i$ and $\ddot{\operatorname{H}}_{2} i$ ( $w$ ith energy $!_{i}$ ): the frequencies for transitions gi ! $\ddot{\mu}_{1} i\left(o r \ddot{\mu}_{2} i\right)$ and $\ddot{\mu}_{1} i\left(o r \ddot{\mu}_{2} i\right)!$ jei are and + , respectively. W ith these notations, the system can be described by

$$
\begin{aligned}
& H=h \quad a a^{y} a+h \quad{ }_{b} b^{y} b
\end{aligned}
$$

where a (b) and $a^{y}\left(b^{y}\right)$ are the annihilation and creation operator for the cavity m ode a (b) w ith frequency a ( b), respectively, $g_{c}$ is the coupling constant of the atom to the cavity m ode a(b) driving the transition gi ! 瓶i
 will not consider the position dependance of the cavityatom coupling $g_{c}(x)$, a good approxim ation in the LambD icke lim it. For the reason of simplicity, we assum e
$a=b=$ hereafter. O ur Schem e works in the follow ing $\lim$ 止: 1)B oth the cavity $m$ ode a and b are strong detuned, i.e., $=!{ }_{i} \gg g_{c} ; \gg$ and $\gg \dot{g}_{c} \tilde{j}=$; and 2) the cavity decay rete $\ll \dot{9}_{c} \dot{J}=$ as required for the high-Q optical cavily. B ecause these transitions
 driven by the two cavity m odes are far o resonant, we $m$ ay adiabatically elim inate the interm ediate states $\ddot{\operatorname{H}}_{1} i$ and $\ddot{\mathrm{j}}_{2} \mathrm{i}$ independently, the H am iltonian (1) then takes the follow ing form $[24,25]$

$$
\begin{align*}
& H=h!a^{y} a+h!b^{y} b+h \quad \text { (jgihe } \dot{a} \mathrm{a}^{\mathrm{y}}+\text { éing }^{\mathrm{y}} \dot{a}^{2} \text { ) } \\
& +\frac{!\mathrm{A}}{2} \text { (jeihej jging) } \\
& +h\left(\dot{g} \text { ine } f \mathrm{~g}^{\mathrm{y}^{2}}+\text { jeing } \mathrm{p}^{2}\right. \text { ); } \tag{2}
\end{align*}
$$

 $T$ his is the H am iltonian which is broadly used to describe the two-photon process, and has received an extensive study during the last decades. For instance, the experim ental realization of a two-photon cascade $m$ icrom aser [26], the generation of Squeezing am pli cation [27] and the creation ofentangled states [28]. O ur proposalw orks $w$ ith a new mechanism di erent from that by making use of very high $K$ err coupling, the coupling betw een the tw o cavity m odes in our protocol, to be discussed below, results from virtual two-photon processes.

In the $\lim$ it $\gg$, i.e., $\left(2!\quad!_{A}\right) \gg \dot{9}_{C} \stackrel{?}{j}=$, the tw o-photon process is on o resonance, we m ay adiabatically elim inate the atom from the system, the H am ilto-
nian (2) then takes the follow ing form in the interaction picture

$$
\begin{equation*}
H_{e f f}=h \xrightarrow{j}\left(a^{y^{2}} a^{2}+b^{y 2} b^{2}+a^{y^{2}} b^{2}+b^{y 2} a^{2}\right) \tag{3}
\end{equation*}
$$

in derivation of the H am iltonian (3), the atom in its ground state jgi initially is assum ed. T he two mode states $w$ ill be de ned in term s of the usual twom ode Fock states in ;ni $=$ in $i_{a}$ jnib $w$ ith $m(n)$ photons in m ode a (b). F inst we consider a sim ple case that there are only two photons in the m ode a while the cavity m ode b in vacuum initially. T he H am iltonian (3) for this sim ple case is equivalent to

$$
H_{e f f}=2 h \frac{j \mathcal{J}}{}\left(\# i_{a} h E j+F i_{b} h E j+\quad \stackrel{+}{a} b+a \quad \begin{array}{c}
+
\end{array}\right) ;
$$

$w$ ith de nition $\# i_{x}=2 i_{x} ; \quad(x=a ; b)$, and $\underset{x}{+()}$ is the pauli operator form ode x . It show s that after the interaction tim e $\mathrm{T}_{0}=\quad=8 j$ j, the tw o cavity m odes evolve to a $m$ axim alentangled state $p^{1} \frac{1}{2}(j E E$ i+ $\ddagger 0 i)$ while leave the atom in its ground state ji. W e would like to note that the non-linear interaction term $\left[a^{\mathrm{y}} \mathrm{b}^{2}+\mathrm{h}: \mathrm{c}:\right]$ is di erent from the $K$ err nonlinear interaction $a^{y 2} a^{2}$ and $a^{y} a b^{y} b$ $[29,30]$, as the latter one is in the form of the square of the free H am ittonian, and hence either $\mathrm{a}^{\mathrm{y}} \mathrm{a}$ or $\mathrm{b}^{\mathrm{y}} \mathrm{b}$ is a constant ofm otion.

W e have perform ed extensive num erical sim ulations w ith the full H am ittonian Eq. (1). Ignoring the atom ic spontaneous em ission and the cavity decay, we nd the above analytical insights to be com pletely accurate, i.e., we indeed get the $m$ axim al entangled state (see Figure 2). In fact, we nd that the approxim ated H am iltonian Eq.(3) is quite an good approach to the full H am iltonian Eq.(1).

T he top panelin $F$ igure 2 show s selected results for the dependance of the population of state j; ;2i(dotted line) and $2 ; 0 i$ (dashed line) on tim e, while the low er panel display the von $N$ eum ann entropy taken in base 2. An initialstate j0; 2 i and system param eters $=20 \mathrm{~g} ;=5 \mathrm{~g}$ are chosen for this plot. T he $m$ axim al entangled state $m$ ay be obtained at tim e $t=785 \mathrm{w}$ ith perfect $F$ idelity ( $\gg 99: 9 \%$ ). The Fidelity is de ned as the overlap betw een the output state and the desired state.

FIG . 2. P opulations of states $-10 ; 2 i$ and $2 ; 0 i$, and the von $N$ eum ann entropy versus time, this gure is plotted for the case when the adiabatic lim it satis ed. The constant line in the top paneldenotes the probability of the atom being in its ground state, disregard where the photons are.

Sim ilar results are found for the initial state $j 4 ; 0 i$, it is illustrated in $F$ igure 3. The di erence is that there are three com ponents $j 4 ; 0 i, 2 ; 2 i$ and $j 0 ; 4 i$ in the output state, their population are show $n$ in the top panel in $F$ igure 3 by c,b,a, respectively. It is interesting to note that there is a tim e point (in $F$ ig. 3, top panel) when line c and line a overlap, which corresponds to the system in $p^{\frac{1}{2}}(j 0 ; 4 i+j 4 ; 0 i)$. And at this point the entropy as plotted in the low er panel is 1 , it equals the entropy of a m axim ally entangled state for two-qubit. A recent study on entangled two modes show that the am ount of entanglem ent present in a given state depends on how one de nes one's system s [31]. This m eans we could redene our tw o m odes such that the state $\frac{1}{2}(-j 0 ; 4 i+j 4 ; 0 i)$ represents a maxim ally entangled state.

FIG . 3. The sam e as in Fig 2, but for the in itial state j4;0i

It is surprising to nd that the sam e dynam ics as in the adiabatic lim it persist even when adiabatic elim ination is not valid. A s an exam ple, in $F$ igure 4 and $F$ igure 5 , we display results for $=8 \mathrm{~g} ;=3 \mathrm{~g}$. A pparently, the atom as the interaction agent for the two cavity $m$ odes is enough for establishing an e ective interaction betw een
them.

FIG.4. The same results as in $F$ igure 2, but for the case where adiabatic elim ination of the atom ic levels is not valid.

F IG .5. The sam e results as in $F$ igure 3, but for the case where adiabatic elim ination of the atom ic levels is not valid.

N ow, we discuss e ects of the dissipation or decoherence due to both the atom ic decay and the cavity loss. A s w ith any proposal for quantum inform ation processing, ultim ately its success depends on being able to com plete m any coherent dynam ics during the decoherence tim e. In principle, as long as a) $\stackrel{2}{->}$ and b) $\stackrel{2}{-}>$, we could expect essentially the sam e results as illustrated in $F$ igure 2 and $F$ igure 3. As there are no real transitions of atom ic states in our proposal, it $m$ akes this schem e im m une to the atom ic spontaneous em ission or atom ic decay, so the restriction b) $m$ ake no sense in this schem e. On the other hand, the condition a) is di cult to achieved because the two-photon process is relatively w eak due to large o -resonant detunings for all its inter$m$ ediate states. In $F$ igure 6 and $F$ igure 7, the e ects of cavity decay on dynam ics of the proposed system is ilhustrated. A s know $n$, the decoherence tim e for a state in ; $n i$ depends on the total num ber of photons, and as F igure 6 and $F$ igure 7 show, relative good results are found when the cavity loss rate is sm all.

FIG.6. Populations for state $\mathcal{2}$; $0 i$ and j0;2i(top panel), as well as the von $N$ eum ann entropy, w ith cavity decay rate
$=0: 005 \mathrm{~g}$, the other param eters chosen are the sam e as in $F$ igure 4.

FIG.7. The same as in Figure 5, but with cavity decay rate $=0: 005 \mathrm{~g}$.
$F$ inally, we want to stress that the requirem ent for the interm ediate states degenerate is not necessary, in fact, our proposalw orks in the sam em anner when the detuning $i$ de ned by $i=\quad!{ }_{i}$ have a di erent sign, i.e.,
$1=\quad 2$. As all existing cavity Q ED -based quantum com putation protocols, optical cavity $w$ th high-Q and atom with sm all decay rate rem ain challenging because of the technological lim it of the Fabry $P$ erot optical cavity [32\{35].

In conclusion, we have proposed a new protocol for preparing the $m$ axim ally entangled state in tw o high-Q optical cavities. A s the photons act as the inform ation carrier, cavity w ith very high-e factor is highly desired. $W$ e have explained the schem $e$ in term $s$ of the virtual two-photon process induced nonlinear interaction. In addition, our protocol can also be explained in term s of entanglem ent distribution by separable states [36]. This new protocol has advantages that its successfiul im plem entation involves no realtransitions of atom ic states, it $m$ akes this proposal im $m$ une to the atom ic spontaneous em ission or atom ic decay.
