#### Abstract

We present a theory of particles, obeying interm ediate statistics (\anyons"), interpolating betw een B osons and Ferm ions, based on the principle ofD etailed B alance. It is dem onstrated that the scattering probabilities of identical particles can be expressed in term s of the basic num bers, which arise naturally and logically in this theory. A transcendentalequation determ ining the distribution function of anyons is obtained in term s of the statistics param eter, whose lim iting values 0 and 1 correspond to Bosons and Ferm ions respectively. The distribution function is determ ined as a pow er series involving the Boltzm ann factor and the statistics param eter and we also express the distribution function as an in nite continued fraction. T he last form enables one to develop approxim ate form $s$ for the distribution function, $w$ th the rst approxim ant agreeing w ith our earlier investigation.

W e form ulate a theory of particles obeying interm ediate statistics, interpolating betw een B osons and Ferm ions, which m ight be called anyons. O ur form ulation will be based on two assum ptions: 1) The exchange sym $m$ etry or perm utation of the coordinates of the particles in the $m$ any particle wave function is accom panied by $m$ ultiplication by a com plex num ber f , thus generalizing the sym $m$ etric or antisym $m$ etric wave functions and 2) The principle of D etailed Balance: if $n_{1} ; n_{2}$ represent the average occupation num bers of states labelled by 1 and 2, then the num ber of transitions ow ing from 1 to 2 m ust equal that ow ing from 2 to 1 at equilibrium .

The particles described by this theory $m$ ay orm ay not be the sam e as the anyons obeying interm ediate or fractional statistics discussed in the literature. T he ob jects nam ed anyons [ 1 8] carry both an electric charge and a magnetic ux. They have attracted a great deal of attention and have been the sub ject of intense investigation in the literature. The anyons arise from the special circum stance in $2+1$ space-tim e dim ensions, where the perm utation group is the braid group and the C hem-Sim ons theory provides a natural realization of the anyons $[9,10]$. There has been a great deal of discussion in the literature on the therm ostatistics of anyons [11]. Since the realw orld is strictly in a $3+1$ dim ensional space, anyons $m$ ay not be realparticles: they could be quasi-particles playing im portant roles in condensed $m$ atter phenom ena. $M$ ore recently, the sub ject ofgeneralized statistics has been investigated in one dim ension in the context ofm any kinds of statistics [12]. In contrast to the theory of anyons fam iliar in the literature, our present approach is not lim ited to tw o space dim ensions and is valid in the real world of $3+1$ dim ensional space-time. It is im portant to point out that this is due to the fact that we do not invoke the spin-statistics theorem and do not require ordinary spin to be interpreted in two dim ensional space.

O n one hand, the theory based only on D etailed B alance does not have the features of the full- edged theory of anyons which takes advantage of the braid group in two dim ensions. On the other hand, in this form ulation we investigate the idea of interpolating statistics only in the context of the statistical m echanics of a gas in equilibrium, without the constraints im posed by quantum eld theory. H ere we shall use the nam e anyons, for convenience, to refer to particles obeying interm ediate statistics, w th the understanding that the present work needs to be developed further by incorporating additional assum ptions before the connection w ith true anyons described in the literature could be established.

The sub ject of anyons has been well investigated in the literature, especially in the context of quantum eld theory and the braid group $[2,5,7,8]$. Interesting results have also been derived to describe the them ostatistics of anyons, such as detem ining the virial coe cients [11,13]. H ow ever, the theoreticalbasis of the statisticalm echanics of anyons has not really been established. For instance, the distribution function for the anyons has not been determ ined in an exact form. We had used an ansatz for the distribution function in our earlier work in order to derive $m$ any of the them odynam ic properties [11]. M ore recently, Chaturvedi and Srinivasan [14] have done a com parative study of the di erent interpolations betw een B oseE instein (BE) and Ferm i-D irac (FD) statistics available in the
literature, in the context of the $m$ ost general interpolations, including $H$ aldane statistics and G entile statistics, w th the conclusion that the distribution function introduced by us [11] has som e desirable features.

C onsequently it is worthw hile to investigate the basic theoretical structure of anyons from the point of view of statistical $m$ echanics and investigate the distribution function of the anyons if possible. This is the goal of this paper. N ot only shall we determ ine the distribution function of the particles obeying the intenpolation statistics, we shall also form ulate a theory which leads to this determ ination w ithout resorting to the restriction to a two dim ensional space. O ur form ulation will be based on the quantum theory of $m$ any particles perm itting a generalized interpolating exchange sym $m$ etry statistics $w$ ith no other assum ptions. Rem arkably, this form ulation leads to an exact theory which requires the em ploym ent of basic num bers.

In Sec.IIwe study the scattering probability ofm any particle states obeying intenpolating statistics. W e establish the fact that the basic num bers arise naturally and logically in this theory. W e introduce them ethod ofD etailed B alance in Sec. III and derive a transcendental equation for the distribution function in term $s$ of the Boltzm ann factor and the statistics determ ining param eter. The distribution function of anyons is studied in Sec. IV where we show that a closed form solution is not possible. W e present the exact solution for the distribution function as an in nite series as well as in the form of an in nite continued fraction which is am enable to approxim ations. Sec. V contains a brief sum $m$ ary and conclusions.

Let us introduce an ensem ble of particles, the anyons, which obey a generalized statistics, interpolating between (BE) and (FD) statistics. $W$ e begin $w$ ith the fram ew ork for building the $w$ ave functions of these anyons by a generalized procedure of $f$-sym $m$ etrizing in such a way that it w ill reduce, in appropriate lim its, to the standard procedure of sym $m$ etrizing for Bosons and anti-sym $m$ etrizing for Ferm ions. The operation of perm utation or exchange of the coordinates of the $m$ any particle wave function results in $m$ ultiplication by the com plex num ber $f$, the exchange sym $m$ etry param eter, so that

Since the $H$ am iltonian has the property $P{ }^{1} H P=H$, it follows that $H\left(P{ }_{n}\right)=E_{n}\left(P n_{n}\right)$ and thus $P{ }_{n}$ is an eigenfunction of the H am iltonian w ith the sam e eigenvalue as ${ }_{n}$. T hus $f{ }_{n}$ is proportional to $n$ and consequently we may take ff ${ }^{\rho}{ }_{n}={ }_{n}$. Hence the general exchange sym $m$ etry that would lead to an interm ediate statistics could be im plem ented by the com plex num ber $f$ w ith the property $\mathrm{f} f=1$. W e shallaccordingly choose the exchange sym $m$ etry to be im plem ented by $f=e^{i} \quad$, where is the statistics determ ining param eter, $0 \quad 1$, so that $\mathrm{f}=\mathrm{f}^{1}$. The lim its $\mathrm{f}!1$; 1 correspond respectively to the BE and FD statistics representing Bosons and Ferm ions. This procedure for inconporating exchange sym $m$ etry am ong anyons is justi ed [7] by the special property of rotations in two dim ensions. H ere we m ay treat it as an assum ption or an ansatz, not restricted to two space dim ensions but valid in any num ber of dim ensions.

Follow ing Feynm an［15］，we consider the two particle scattering am plitude de ned by the product $a_{1} b_{2}$ ，where $a_{1}=h 1$ jai describes the scattering of particle a into state 1 and $\mathrm{b}_{2}=\mathrm{h} 2$ toi describes the process b！ $2 . \mathrm{W}$ e shall take 1 and 2 to be the sam e state at the end in order to deal w ith identical particles．The exchange sym m etry has to do $w$ ith the process corresponding to $a!2 ; b!1$ which is indistinguishable from the direct process and the amplitude for this process would be $f a_{2} b_{1}$ due to the exchange factor $f$ ．The total probability amplitude is the sum of the direct and exchange processes．Employing the abbreviation $\mathrm{h} 1 \dot{\mathrm{j}} \mathrm{i}=\mathrm{h} \dot{\operatorname{jaj}}=\mathrm{a}$ ，we nd the probability of this two particle scattering process involving non－identical particles to be
since ff ${ }^{?}=1$ ．This probability is the same as for ordinary Bosons［15］．H owever，for identical particles，we need to take account of interference between the two processes and that $m$ akes a great deal of di erence．W e obtain the probability in this case to be

$$
\begin{equation*}
\mathrm{p}_{\text {identical }}^{(2)}=\left(1+\dot{\mathrm{f}} \mathrm{~J}^{\mathcal{J}}+\mathrm{f}+\mathrm{f}^{1}\right) \text { 自予别; } ; \tag{3}
\end{equation*}
$$

since $f=f^{1}$ and this probability depends on the statistics determ ining param eter．In the $\lim$ it $f!1$ ，this would reduce to the case of Bosons and it would be tw ice as much as in Eq．（2）for the non－identical particles．For arbitrary $f$ the probability for the process involving identical particles relative to that for non－identical particles is given by
 norm alized．U nderstanding this to be a proportionality，we m ight henœforw ard refer to this itself as the probability for the process，or just the probability of the tw o particle state，for sim plicity．

Sim ilarly，we consider the three－particle processes a！1；b！2；c！ 3 together with the exchange processes $w$ th factor $f$ for each exchange operation，thus resulting in the combination abc $+f a d b+f$ bac $+f^{2} b c a+f^{2} c a b+f^{3}$ doa $w$ th the same abbreviation as earlier．W e can now determ ine the probability for the three particle process，or just for the three particle state $w$ ith identical particles，as

$$
\begin{equation*}
P^{(3)}=\frac{1}{6}\left(1+2 f^{1}+2 f^{2}+f^{3}\right)\left(1+2 f+2 f^{2}+f^{3}\right): \tag{5}
\end{equation*}
$$

W e can reduce this to the form

$$
\begin{align*}
P^{(3)} & =\frac{1}{6}^{n} 10+8\left(f+f^{1}\right)+4\left(f^{2}+f^{2}\right)+\left(f^{3}+f^{3}\right)^{0} \\
& =\frac{1}{6}{ }^{n} 6+7\left(f+f^{1}\right)+4\left(f^{2}+f^{2}+1\right)+\left(f^{3}+f^{3}+f+f^{1}\right)^{0}: \tag{6}
\end{align*}
$$

R ecognizing the pattem here, we observe that the right hand side in the expressions for the probabilities in Eqs. (4), (5), (6) contain basic num bers [16], w ith the base f. They are indeed expressed succinctly in term s of the basic num bers de ned by

$$
\begin{equation*}
[\mathrm{n}]_{\mathrm{f}}=\frac{\mathrm{f}^{\mathrm{n}} \mathrm{f}^{\mathrm{n}}}{\mathrm{f}} \frac{\mathrm{f}^{1}}{}: \tag{7}
\end{equation*}
$$

$W$ e shall henceforw ard om it the subscript $f$ for $\sin$ plicity. Here $f=e^{i}$, the BE lim it is ! 0;f! 1 and the FD lim it is ! $1 ; f!1$ and $f=f^{1}$. Our formulation is sym $m$ etric under $f!f^{1}$ and is the fam iliar generalization of the basic num bers introduced long ago by F.H.Jackson [16]. Studying the lim its we nd that the Bose lim it gives [n]! n while the Ferm ilim it is quite di erent: [n]! ( 1$)^{p+1} n$ which becom es $n$ foreven numbers and +n for odd num bers. In this lim it, we are therefore dealing w ith a generalization of ordinary ferm ions for which the exclusion principle is not autom atically valid: in the FD lim it it can be im posed by hand only. Retuming to the basic num bers introduced in Eq. (7), it is quite evident in Eqs. (4), (5), (6), and as will be seen in m ore detail below, that the basic num bers arise naturally, autom atically, in the theory of particles obeying interpolating statistics. This feature is quite new and not recognized in the standard theory of anyons in the literature. This $m$ ight be an indication that the theory of interpolating statistics naturally involves a deform ation of the system such as that described by the basic num ber system w ith its consequences, w ithout how ever introducing a deform ed algebra of operators.

In addition to the representation,

$$
\begin{equation*}
[\mathrm{n}]=\mathrm{f}^{\mathrm{n} 1}+\mathrm{f}^{\mathrm{n} 3}+\quad \mathrm{f}^{\mathrm{n}} \mathrm{f}^{3}+\mathrm{f}^{\mathrm{n}+1} ; \tag{8}
\end{equation*}
$$

the follow ing representation of the bracket num ber

$$
\begin{equation*}
[n]=\frac{\sin n}{\sin } ; \tag{9}
\end{equation*}
$$

$w$ ill be found $m$ ost useful. In term $s$ of the basic num bers, the probabilities $m$ ay now be expressed conveniently and succinctly as

$$
\begin{align*}
& P^{(2)}=\frac{1}{2}(2+[2]) ; \\
& P^{(3)}=\frac{1}{6}(6+7[2]+4[3]+[4]) ; \\
& P^{(4)}=\frac{1}{4!}(35+54[2]+52[3]+36[4]+18[5]+6[6]+[7]) ; \tag{10}
\end{align*}
$$

and so on. $W$ e can derive a usefiul result,

$$
\begin{equation*}
[1]+[3]+[5]+\quad+[2 n \quad 1]=(\text { 员 } \xi) \tag{11}
\end{equation*}
$$

which can be proved by using [17] the identity,

$$
\begin{equation*}
\frac{1}{\sin t}_{k=1}^{x^{n}} \sin (2 k \quad 1) t={\frac{\sin n t^{2}}{\sin t}}^{2}: \tag{12}
\end{equation*}
$$

W e shall also nd the follow ing result quite useful:

$$
\left[\begin{array}{ll}
n & 1
\end{array}\right][n]=[2]+[4]+[6]+\quad\left[2\left(\begin{array}{ll}
n & 1 \tag{13}
\end{array}\right)\right]:
$$

In other words, [2] [3] = [2] + [4]; [3] [4] = [2] + [4]+ [6]; etc. This is proved by using the identity

$$
\begin{equation*}
\mathbb{x}^{1} \sin k y=0 \sin \frac{(n \quad 1) y}{2} \sin \frac{n y}{2} \csc \frac{y}{2}: \tag{14}
\end{equation*}
$$

T hese identities can be used to re-express Eqs. (10) in the form

$$
\begin{align*}
& \mathrm{P}^{(2)}=\frac{1}{2}(2+[2]) ; \\
& \mathrm{P}^{(3)}=\frac{1}{3!}(2+[2])(2+2[2]+[3]) ; \\
& \mathrm{P}^{(4)}=\frac{1}{4!}(2+[2])(2+2[2]+[3])(2+2[2]+2[3]+[4]): \tag{15}
\end{align*}
$$

In this $m$ anner, generalizing to $n$ particles, we are led to the probability for the n-anyon state:

$$
\begin{equation*}
P^{(n)}=\frac{1}{n!}(2+[2])(2+2[2]+[3]) \quad(2+2[2]+2[3]+\quad+2[n \quad 1]+[n]): \tag{16}
\end{equation*}
$$

## III. DETAILED BALANCE

From Eq. (16), we can infer the enhancem ent factor, which is a m easure of how much greater the probability of the $n+1$-particle state is, com pared to the probability of the n-particle state. For now, we sim ply express it as

$$
\begin{equation*}
F(n)=\frac{P^{(n+1)}}{P^{(n)}} \tag{17}
\end{equation*}
$$

which can be determ ined from Eq.(16). This enhancem ent factor provides the essential step in the m ethod ofD etailed B alance. This brings us to the second assum ption upon whidh our theory of interpolating statistics rests: if $n_{1} ; n_{2}$ represent the average occupation num bers of states 1 and 2 respectively, then the num ber of transitions ow ing from 1 to 2 m ust equal that ow ing from 2 to 1 at equilibrium. This is the principle of D etailed Balance. W e should stress that this principle is characteristic of them odynam ic equilibrium and may be regarded as a consequence of the second law of therm odynam ics [18]. Indeed the principle of D etailed Balance is valid when therm odynam ic equilibrium prevails or the validity of $m$ icroscopic reversibility in the language of statistical physics. This notion is based on the reversibillty of the $m$ icroscopic equations of $m$ otion, or on the $H$ erm itian nature of the scattering $H$ am iltonian [19]. T he principle of $D$ etailed $B$ alance can thus be stated as

$$
\begin{equation*}
\mathrm{n}_{1} \mathrm{~F}\left(\mathrm{n}_{2}\right) \mathrm{e}^{\mathrm{E}_{1}}=\mathrm{n}_{2} \mathrm{~F}\left(\mathrm{n}_{1}\right) \mathrm{e}^{\mathrm{E}_{2}} ; \tag{18}
\end{equation*}
$$

where the population of each level is govemed by the Boltzm ann factor and $F(n)$ is the enhancem ent factor. This yields

$$
\begin{equation*}
\frac{n}{F(n)} e^{E}=\text { constant }=z \text {; } \tag{19}
\end{equation*}
$$

which would, in principle, enable us to determ ine the distribution function for the anyons in term s of the Boltzm ann factor. In the BE lim it for instance, the enhancem ent factor is just $n+1$, which im m ediately leads to the BE distribution

$$
\begin{equation*}
n=\frac{1}{z^{1} e^{E}}: \tag{20}
\end{equation*}
$$

where $z=e$ is the fugacity of the gas. Let us now proceed in the sam e manner for arbitrary $f$. The enhancem ent factor for arbitrary $f$ is given by Eqs.(16) and (17) which reduces to the sim ple form

$$
\begin{equation*}
F(n)=\frac{P^{(n+1)}}{P^{(n)}}=\frac{1}{n+1}(2+2[2]+2[3]+\quad 2[n]+[n+1]): \tag{21}
\end{equation*}
$$

To proceed further, we em ploy the result

$$
x_{k=0}^{x^{n}}[k]=2 \cos (=2)[n=2][(n+1)=2] ;
$$

which is easy to prove by using identities involving sum $s$ of trigonom etric functions. This gives us the follow ing result for $F(n)$, after som e algebra:

$$
\begin{equation*}
F(n)=\frac{1}{n+1} 2 \cos (\quad=2)[(n+1)=2] f[n=2]+[n=2+1] g: \tag{23}
\end{equation*}
$$

W e can also derive another identity

$$
\begin{equation*}
[n=2]+[n=2+1]=2 \cos (\quad=2)[(n+1)=2] ; \tag{24}
\end{equation*}
$$

which can be used to sim plify the above result. H ence we obtain

$$
\begin{equation*}
F(n)=\frac{4}{n+1} f[(n+1)=2] \cos (=2) g^{2}: \tag{25}
\end{equation*}
$$

W e observe that this reproduces the expected result $F(n)!n+1$ in the B ose lim it. Upon now invoking the $D$ etailed B alance we obtain the im portant result

$$
\begin{equation*}
\frac{1}{z} e^{E}=F(n)=n=\frac{4}{n(n+1)} f[(n+1)=2] \cos (\quad=2) g^{2}: \tag{26}
\end{equation*}
$$

This can be rew ritten in the follow ing convenient form in order to dealw ith the distribution function:

$$
\begin{equation*}
e^{(E)}=\frac{1}{n(n+1)} \frac{\sin ^{2}(n+1)=2}{\sin ^{2}=2}: \tag{27}
\end{equation*}
$$

Solving this equation should, in principle, lead to the distribution function for the anyons in this form ulation. At this point before dealing $w$ th the distribution function, we need to study the nature of the interm ediate statistics as an interpolation betw een the BE and FD lim its. Speci cally we need to study the lim its corresponding to BE and FD statistics.

W e have already observed that $F(n)!n+1$ in the Bose lim it, $f!$ 1. Indeed, it is readily veri ed that Eq. (26) reproduces the correct BE statistical distribution. The case of Ferm ilim it, ! $1 ; f!1$, is, however, som ewhat complicated. W e have: [i]! n; $n$ for odd and even occupation num bers respectively. Evaluating the lim it in Eq. (26), the enhancem ent factorm ay be put in the form,

$$
\begin{equation*}
\lim _{!1} F(n)=\frac{1}{n+1} \quad \operatorname{Im} e^{i(n+1)}=2^{2} ; \tag{28}
\end{equation*}
$$

thus resulting in a generalized Ferm ion theory. This corresponds to an in nite dim ensional representation analogous to the generalized ferm ions investigated by Chaichian et al. Ifwe consider only $n=0 ; 1$; and im pose the exclusion principle $\backslash$ by hand", then $F(n)!1 ; 0$. This is equivalent to $F(n)!1 \quad n$ and in this case it reproduces the standard Ferm idistribution w ith the exclusion principle. For arbitrary n, which is allowed, however, it is an in nite value representation

$$
\begin{equation*}
\lim _{!1} F(n)=\frac{1}{n+1} f 1 ; 0 ; 1 ; 0 ; 1 ; \quad g ; \tag{29}
\end{equation*}
$$

and we nd that $F(n)$ has repeating values $1=(n+1)$ and 0 in the lim it ! 1 ; ! 1 . $T$ his is thus a special and interesting feature of this theory. Thus for arbitrary values of the param eter $f$, including the Ferm ilm it $f!$ 1, the theory of interm ediate statistics requires the existence of generalized ferm ions beyond the exclusion principle.
IV.THE D ISTRIBUTION FUNCTION

W e begin by rew riting Eq. (27) in the form

$$
\begin{equation*}
\left.e^{(E} \quad\right)=\frac{1}{n(n+1)} \frac{\sin ^{2}(n+1) x}{\sin ^{2} x}: \tag{30}
\end{equation*}
$$

Here $\mathrm{x}=\quad=2$ in term s of the statistics determ ining param eter. T he ob ject is to determ ine the average occupation num bern, the distribution fiunction, so that we can com pare w th the standard BE or FD distribution and understand the nature of the interpolating statistics. W e can expand the right hand side in a power series

$$
\begin{equation*}
e^{(E)}=\frac{1}{n}+a_{0}+a_{1} n+a_{2} n^{2}+a_{3} n^{3}+\quad ; \tag{31}
\end{equation*}
$$

where

$$
\begin{align*}
& a_{0}=\csc ^{2} x\left(x \sin 2 x \quad \sin ^{2} x\right) \\
& a_{1}=\csc ^{2} x\left(x^{2} \cos 2 x \quad x \sin 2 x+\sin ^{2} x\right) \\
& a_{2}=\csc ^{2} x \quad x^{2} \cos 2 x \quad \sin ^{2} x+\left(\begin{array}{ll}
x & 2 x^{3}=3
\end{array}\right) \sin 2 x^{\circ} \\
& a_{3}=\csc ^{2} x^{n}\left(x^{2} \quad x^{4}=3\right) \cos 2 x+\sin ^{2} x \quad\left(x \quad 2 x^{3}=3\right) \sin 2 x^{\circ} ; \tag{32}
\end{align*}
$$

and so on. The coe cients to any desired order can be obtained by using $M$ athem atica. It is clear that $a_{0}$ ! 1 ; while $a_{n}$ ! 0 for $n \quad 1$ in the Bose lim it, which is consistent w ith the BE distribution as described in Sec. III. In the case of the Ferm ilim it, $a_{0}!1$ and it leads to the generalized ferm ions. W e can rew rite the above as

$$
\begin{equation*}
\frac{1}{g}=n \quad \frac{a_{1}}{g} n^{2} \quad \frac{a_{2}}{g} n^{3} \quad \frac{a_{3}}{g} n^{4} \quad: \tag{33}
\end{equation*}
$$

where $g=e^{(E)} a_{0}$.This series can be reverted to express $n$ as a series in powers of $1=g$, thus

$$
\begin{equation*}
\mathrm{n}=1=\mathrm{g}+\mathrm{B}=\mathrm{g}^{2}+\mathrm{C}=\mathrm{g}^{3}+\mathrm{D}=\mathrm{g}^{4}+\mathrm{E}=\mathrm{g}^{5}+\mathrm{F}=\mathrm{g}^{6} \quad ; \tag{34}
\end{equation*}
$$

where

$$
\begin{align*}
& B=a_{1}=g ; C=\left(2 a_{1}^{2}=g^{2}+a_{2}=g\right) ; D=\left(5 a_{1} a_{2}=g^{2}+a_{3}=g+5 a_{1}^{3}=g^{3}\right) ; \\
& \mathrm{E}=\mathrm{E}=6 \mathrm{a}_{1} \mathrm{a}_{3}=\mathrm{g}^{2}+3 a_{2}^{2}=\mathrm{g}^{2}+14 \mathrm{a}_{1}^{4}=\mathrm{g}^{4}+\mathrm{a}_{4}=\mathrm{g}+21 \mathrm{a}_{1}^{2} \mathrm{a}_{2}=\mathrm{g}^{3} \text {; } \\
& F=7 a_{1} a_{4}=g^{2}+7 a_{2} a_{3}=g^{2}+84 a_{1}^{3} a_{2}=g^{4}+a_{5}=g+28 a_{1}^{2} a_{3}=g^{3}+28 a_{1} a_{2}^{2}=g^{3}+42 a_{1}^{5}=g^{5} ; \tag{35}
\end{align*}
$$

and so on. U pon rearrangem ent, we can rew rite the above form for the distribution fiunction as the follow ing series:

$$
\begin{align*}
\mathrm{n}(\mathrm{E}) & =1=g+a_{1}=g^{3}+a_{2}=g^{4}+\left(2 a_{1}^{2}+a_{3}\right)=g^{5} \\
& +\left(5 a_{1} a_{2}+a_{4}\right)=g^{6}+\left(5 a_{1}^{3}+6 a_{1} a_{3}+3 a_{2}^{2}+a_{5}\right)=g^{7}+ \tag{36}
\end{align*}
$$

W e observe that this is a power series in $1=g$ but the term $w$ th $1=g^{2}$ is absent. W e can rew rite Eq.(36) in the form
where

$$
\begin{equation*}
{ }_{3}=a_{1} ; \quad 4=a_{2} ; 2 a_{1}^{2}+a_{3}=5 ; 5 a_{1} a_{2}+a_{4}=6 ; \tag{38}
\end{equation*}
$$

etc. $W$ e can now express this in the form of a continued fraction. $W$ e invoke the standard algorithm which can be introduced as follow s [21]. If a continued fraction is of the form

$$
\begin{equation*}
\frac{\mathrm{B}_{\mathrm{n}}}{\mathrm{C}_{\mathrm{n}}}=\mathrm{c}_{0}+\frac{\mathrm{b}_{1}}{\mathrm{c}_{1}+\frac{\mathrm{b}_{2}}{\mathrm{c}_{2}+}} ; \tag{39}
\end{equation*}
$$

then the successive convergents (approxim ants) are obtained by the recurrence form ulae

$$
\begin{equation*}
\mathrm{B}_{\mathrm{n}}=\mathrm{C}_{\mathrm{n}} \mathrm{~B}_{\mathrm{n} 1}+\mathrm{b}_{\mathrm{n}} \mathrm{~B}_{\mathrm{n} 2} ; \quad \mathrm{C}_{\mathrm{n}}=\mathrm{C}_{\mathrm{n}} \mathrm{C}_{\mathrm{n} 1}+\mathrm{b}_{\mathrm{n}} \mathrm{C}_{\mathrm{n} 2} ; \mathrm{B}_{1}=1 ; \mathrm{C}_{1}=0: \tag{40}
\end{equation*}
$$

T hus in order to put the series in Eq.(37) in the continued fraction form, we proceed w ith the rst convergent and set $G=B_{0}=C_{0}=0$. U sing the recurrence relations, Eq.(40), we determ ine $B_{0}=0 ; C_{0}=1 ; b_{1}=1 ; C_{1}=g ; B_{1}=1 ; C_{1}=g$. This determ ines the rst convergent as $\mathrm{n}=1=\mathrm{g}$. N ext, the recurrence relations lead to $\mathrm{b}_{2}={ }_{3} \mathrm{~g}_{;} \mathrm{C}_{2}=\mathrm{g}^{2}+{ }_{3} ; \mathrm{B}_{2}=$ $g^{2}+{ }_{3} ; \mathrm{C}_{2}=\mathrm{g}^{3}$ which determ ines the second convergent to be

$$
\begin{equation*}
n=\frac{1}{9 \frac{{ }_{3} 9}{9^{2}+3}}: \tag{41}
\end{equation*}
$$

Continuing on with successive convergents in this $m$ anner, we obtain the desired in nite continued fraction form for the distribution function as follow $s$

This is the distribution function in the exact theory, albeit not in a closed form. Approxim ations can be im plem ented in order to investigate the them ostatistical properties of the anyons. The rst approxim ant,

$$
\begin{equation*}
\mathrm{n}(\mathrm{E})=\frac{1}{\left.\mathrm{e}^{\mathbb{E}}\right) \mathrm{a}()} ; \tag{43}
\end{equation*}
$$

was indeed em ployed, as an ansatz, in our earlier investigation [11]. It m ight be pointed out that the continued fraction form is $m$ athem atically desirable in view of the fact that it can be expressed as a ratio of polynom ials, hence analytic in the variable as well as o ering the best approxim ation possible. This form is also am enable to investigation in term s of $P$ ade approxim ants.

F inally it m ust be pointed out that Eq.(42) is an exact expression for the distribution function, albeit in the form of an in nite continued fraction, and can be determ ined explicitly for any speci c value of the param eter, either as an in nite continued fraction, or to any desired approxim ation. For instance, for the case of $=\frac{1}{2}$, the exact form of the distribution function is

$$
\begin{equation*}
n(E) j_{=\frac{1}{2}}=\frac{1}{g+\frac{a_{0} g}{\left.g^{2} \quad a_{0}+\frac{\left(a_{0}\right.}{a_{0} g}{ }^{3}=48\right) g}\left(a_{0}{ }^{3}=48\right)+} ; \tag{44}
\end{equation*}
$$

where $a_{0}\left(\frac{1}{2}\right)==2 \quad 1$.

The them odynam ic distribution function of anyons in two space dim ensions, obeying interpolating statistics is not known in the literature and is an open question. W e have not only found an answ er, thus determ ining the distribution function, we have also dem onstrated that the theory describing interpolating statistics has several rem arkable and interesting features. O ur investigation leads to a generalized de nition of perm utation sym $m$ etry in arbitrary di$m$ ensions and not restricted to two space dim ensions. W e have shown that the theory of perm utation sym $m$ etry that w ould describe particles obeying intenpolating statistics is succinctly form ulated in the language of basic num bers. T hese basic num bers arise naturally and autom atically in this form ulation but do not explicitly invoke any deform ed oscillator algebra. O ur theory is based on the principle of D etailed B alancing which is a consequence of the Second law of therm odynam ics. Furtherm ore, this form ulation leads to the determ ination of the exact distribution function, w ithout having to introduce any approxim ation. In this m anner, we have form ulated the theory which leads to a transcendental equation for the distribution function of anyons in term $s$ of the statistics determ ining param eter and the B oltzm an factor containing the energy of the state. W e obtain a solution of this equation whidh we express as a power series as well as in the form of a continued fraction. W e show that the rst approxim ation of this theory reproduces a form of the distribution fiunction introduced by us in an earlier investigation.

An im portant feature of our form ulation consists of the fact that the basic num bers arise naturally and autom atically in this theory, speci cally the sym m etric form ulation of the basic num bers. T he basic num bers arise autom atically in our theory but they are not part of an oscillator algebra, nor do we introduce the construction ofFock space for the particles obeying the interm ediate statistics. T he theory reduces to BE statistics in the Bose lim it, f ! 1; ! 0. The Fermilim it, f ! 1; ! 1 leads to generalized ferm ions beyond the exclusion principle and thus correspond to in nite dim ensional representation and they reduce to the fam iliar FD statistics only when $n$ is restricted to 0,1 by hand.

A though the algebra of $q$-oscillators appears in the literature on the sub ject of anyons $[7,8,20]$, it is also know $n$ that q-oscillators $m$ ay have nothing to do $w$ ith anyons since the for$m$ er exist in arbitrary space-tim e dim ensions. In our form ulation, we do not use q-oscillator algebra, neither do we use Fock states. W e do not make use of the H am iltonian other than to recognize that the $H$ am ittonian should be of a form that perm its D etailed Balance. T he $H$ am iltonian consists of only the kinetic energy term $s$ and is the free $H$ am iltonian [5] in the anyon gauge and the anyon wave functions satisfy \tw isted" boundary conditions.

It is interesting that the rst approxim ant ( rst convergent) of our solution corresponds to the approxim ate form for the distribution function

$$
\begin{equation*}
\mathrm{n}(\mathrm{E})=\frac{1}{\left.\mathrm{e}^{\mathrm{E}}\right) \mathrm{a}()} \tag{45}
\end{equation*}
$$

which is the form introduced in an earlier investigation [11]. It is interesting that this also agrees w ith the partition function derived by them ethod ofG reen function [20], to rst order
approxim ation. It should be stressed that while the form above is a point of agreem ent for an approxim ate theory, the form of a in the present form ulation as in Eq. (32), as a function of the statistics determ ining param eter, is very di erent from that of [11]. F inally we obtain the exact form of the distribution function for the case $=\frac{1}{2}$ in the form of a continued fraction which can be evaluated to any desired order. Such a form for the distribution function can indeed be obtained for any chosen value of , the statistics determ ining param eter

It is ofm uch interest that this form ulation leads to an interm ediate statisticalm echanics, interpolating between BE and FD, without explicit use of the special properties valid in 2+ 1 space-tim e dim ensions, but only stem s from the principle of $D$ etailed Balance. This contrasts with investigations in the literature of anyons which arise from the braid group in the special case of $2+1$ space-tim e. A s is seen from Eq. (30), the dependence on the statistics determ ining param eter is through a quadratic function, hence invariant under ! , im plying a clockw ise-oounterclockw ise sym $m$ etry of the braid [6]. It would be worthw hile to continue this investigation further in order to explore the relation to these anyons. A s this form ulation reveals several desirable and interesting theoretical features, it is appropriate to pose som e questions such as the follow ing. D oes the generalization to any space dim ensions im ply that the connection w ith C hem-Sim ons type of gauge theory can be extended beyond two space dim ensions? Is it possible to form ulate the partition problem corresponding to this generalized, exact theory? Is it possible to determ ine the $m$ any useful therm odynam ic properties of the system described by such an exact theory? These questions will occupy us in further investigations of this theory.
