Sem iclassical tim e-evolution of the reduced density $m$ atrix and dynam ically assisted generation of entanglem ent for bipartite quantum system $s$

Ph. Jacquod ${ }^{1}$<br>${ }^{1}$ D epartem ent de P hysique $T$ heorique, U niversite de G eneve, C H-1211 G eneve 4, Sw itzerland (D ated: February 16, 2004)

#### Abstract

T w o particles, in itially in a product state, becom e entangled when they com e together and start to interact. U sing sem iclassicalm ethods, we calculate the tim e evolution of the corresponding reduced density $m$ atrix ${ }_{1}$, obtained by integrating out the degrees of freedom of one of the particles. To quantify the generation ofentanglem ent, we calculate the purity $P(t)=\operatorname{Tr}\left[1_{1}(t)^{2}\right]$. We nd that entanglem ent generation sensitively depends (i) on the interaction potential, especially on its strength and range, and (ii) on the nature of the underly ing classical dynam ics. U nder general statistical assum ptions, and for short-ranged interaction potentials, we nd that $P$ ( $t$ ) decays exponentially fast if the two particles are required to interact in a chaotic environm ent, whereas it decays only algebraically in a regular system. In the chaotic case, the decay rate is given by the golden rule spreading of one-particle states due to the two-particle coupling, but cannot exceed the system 's Lyapunov exponent.

W hen two system s (...) enter into tem porary interaction (...), and when after a tim e of mutual in uence the system s separate again, then they can no longer be described in the same way as before, viz. by endowing each of them with a representative of its own. This is how entanglem ent was characterized by Schrodinger alm ost seventy years ago $\left.{ }_{[1]}^{1}\right]$. E ntanglem ent is arguably the m ost puzzling property ofm ultipartite quantum system s , and often leads to counterintuitive predictions due to, in E instein's words, spooky action at a distance. E ntanglem ent has received a renew ed, intense interest in recent years in the context of quantum inform ation theory [].

In the spirit of Schrodinger's above form ulation, one is naturally led to ask the follow ing question: \W hat deter$m$ ines the rate ofentanglem ent production in a dynam ical system ?". Is this rate $m$ ostly determ ined by the interaction betw een tw o, initially unentangled particles, or does it depend on the underlying classicaldynam ics ? This is the question we address in this paper. P revious attem pts to answ er this question have m ostly focused on num erical
 glem ent is favored by classical chaos, both in the rate it is generated $\left[\begin{array}{lll}1 \\ \hline\end{array}, \overline{1}, 1,1\right]$ reach [J]- In particular, strong num erical evidences have been given by M iller and Sarkar for an entanglem ent production rate given by the system 's Lyapunov exponents [4]']. These ndings have how everbeen recently challenged by Tanaka et al. [GG], whose num erical ndings show no increase of the entanglem ent production rate upon increase of the Lyapunov exponents in the strongly chaotic but w eakly coupled regim e , in agreem ent w ith their analyticalcalculations relating the rate ofentanglem ent production to classicaltim e correlators. Ref. [G] $[\underline{[6]}$ is seem ingly in a paradoxical disagreem ent $w$ ith the alm ost identical analytical approach of $R$ ef. [1]1], where entanglem ent production was found to be faster in chaotic system $s$ than in regular ones $\left[\frac{[1}{[1]}\right]$. This controversy thus calls for a better analytical understanding of the problem.

W e present a sem iclassical calculation of the tim e-
evolved density m atrix (t) for two interacting, distinguishable particles. In the usual way, entanglem ent is quanti ed by the properties of the reduced density m atrix ${ }_{1}(t) \quad T r[(t)]$, obtained from the two-particle density $m$ atrix by tracing over the degrees of freedom of one (say, the second) particle. At $t=0$, the two particles are in a product state of two narrow w avepackets. W e w ill quantify entanglem ent by calculating the purity $P$ ( $t$ ) $\operatorname{Tr}\left[1(t)^{2}\right]$ which varies from 0 for fillly entangled to 1 for factorizable two-particle states [10 $\left.0_{1}^{\prime}\right]$ (the discussion ofhow this could translate into the violation of a B ell inequality [1] in in is postponed to later works). C om pared to other $m$ easures of entanglem ent such as the von $N$ eu$m$ ann entropy or the concurrenœ, the purity presents the advantage of being analytically tractable. For the w eak coupling situation we are interested in here, num erical works have $m$ oreover shown that von $N$ eum ann and linear entropy $S_{\text {lin }} \quad 1 \quad P(t)$ behave very sim ilarly ill b]. W e thus expect the purity to give a faithful and generic $m$ easure of entanglem ent. W e note that our sem iclassical approach is straightforw ardly extended to the case ofundistinguishable particles, provided the nonfactorization of the reduced density $m$ atrix due to particle statistics is properly taken care of $[1212]$.

O ur approach is rem iniscent of the sem iclassicalm eth-
 also [ $\left.\left[1 \bar{S}_{1}^{\prime}\right]\right)$ in the context of the Loschm idt E cho. We w ill show how the o-diagonalm atrix elem ents of 1 are related to classical action correlators, in a sim ilar way as
 tions, we nd that, follow ing an intial transient where
1 relaxes but rem ains alm ost exactly pure, entangle$m$ ent production is exponential in chaotic system S , while it is algebraic in regular system s . T he asym ptotic rate of entanglem ent production in chaotic system $s$ depends on the strength of the interaction betw een the tw o particles, and is explicitely given by a classicaltim e-correlator. We e note that, as is the case for the Loschm idt E cho $\left[\begin{array}{l}1 \\ 1\end{array}, \overline{1}, \overline{1}_{2} \overline{7}_{-}\right]$, this regim e is also adequately captured by an approach
based on $R$ andom $M$ atrix $T$ heory (RM T) $\left[\overline{2 n}^{-1}\right]\left\{\right.$ the tim $e^{-}$ correlator is then replaced by the golden rule spreading of one-particle states due to the interaction. For stronger coupling however, the dom inant stationary phase solution becom es interaction independent, and is determ ined only by the classical dynam ics, the system 's Lyapunov exponents giving an upperbound for the rate ofentangle$m$ ent production. T he crossoverbetw een the tw o regim es occurs once the golden rule w idth becom es com parable to the system 's Lyapunov exponent. Still, one has to keep in m ind that long-ranged interaction potentials can lead to signi cant m odi cations of this picture, especially at short tim es, due to an anom alously slow vanishing ofo diagonal $m$ atrix elem ents of 1 within a bandw idth set by the interaction range.

We start with an initial two-particle product state $j_{1} i \quad j_{2} i \quad j_{1} ;{ }_{2} i$. The state of each particle is a G aussian wavepacket $1 ; 2(y)=\left({ }^{2}\right)^{d=4} \exp \left[i p_{0} \quad(y\right.$ $r_{1 ; 2}$ ) iy $\quad ¥_{;} \tilde{j}^{f}=2^{2}$ ]. W e w rite the two-particle H am irtonian as H $=\mathrm{H} \quad \mathrm{I}+\mathrm{I} \quad \mathrm{H}+\mathrm{U}$, i.e. the two particles are sub jected to the same H am iltonian dynam ics. At this point, we only specify that the interaction potential U is sm ooth, depends only on the distance betw een the particles, and is characterized by a typical length scale (which can be its range, or the scale over which it uctuates). Setting h 1, the two-particle density m atrix evolves according to $(\mathrm{t})=\exp [\mathrm{iH} t]_{0} \exp [\mathrm{iH} t]$ starting initially $w_{R}{ }^{\text {th }} 0=j 1 ; 2$ ih $1 ; 2 j$. The elem ents ${ }_{1}(x ; y ; t)=d r h x ; r j(t)$ y; ri of the reduced density $m$ atrix read

$$
\begin{align*}
& \exp \left[i p_{0}\left(y_{1}+y_{2} \quad y_{3} \quad y_{4}\right)\right] h x ; r j \exp [\quad i H t] \sum_{1} ; y_{2} \text { ihy }{ }_{3} ; y_{4} j \exp [i H t] \dot{y} ; r i: \tag{1}
\end{align*}
$$

W e next introduce the sem iclassical tw o-particle propagator

$$
h x ; r j \exp [\quad i H t] \sum_{1} ; y_{2} i=(\quad i)^{d} \underset{s ; s^{0}}{X} \quad C_{s ; s^{0}}^{1=2} \exp \left[i f S_{s}\left(y_{1} ; x ; t\right)+S_{s^{0}}\left(y_{2} ; r ; t\right)+S_{s ; s^{0}}\left(y_{1} ; x ; y_{2} ; r ; t\right) \quad \overline{2}\left(s_{s}+\quad s^{0}\right) g\right] ;
$$

which is expressed as a sum over pairs of classical tra jectories, labelled $s$ and $s^{0}$, respectively connecting $y_{1}$ to x and $Y_{2}$ to $r$ in the tim et. Each such pair of paths gives a contribution containing one- (denoted by $S_{s}$ and $S_{s^{0}}$ ) and twoparticle (denoted by $S_{s ; s^{0}}={ }_{0} d t_{1} U\left(q_{s}\left(t_{1}\right) ; q_{s^{0}}\left(t_{1}\right)\right)$ [2] $]$ ) action integrals accum ulated along $s$ and $s^{0}$, a pair of $M$ aslov indioes $s$ and $s^{0}$, and the determ inant $C_{s ; s^{0}}$ of the stability $m$ atrix corresponding to the two-particle dynam ics in the (2d) dim ensional space. ( W ith the above de nition, $\mathrm{C}_{\mathrm{s} ; \mathrm{s}^{0}}$ is real and positive.) W e consider su ciently sm ooth interaction potentials varying over a distancem uch larger than.$W$ e thus set $S_{s ; s^{0}}\left(y_{1} ; x ; y_{2} ; r ; t\right){ }^{\prime} S_{s ; s^{0}}\left(r_{1} ; x ; r_{2} ; r ; t\right)$ (still we keep in $m$ ind that $r_{1}$ and $r_{2}$, taken as argum ents of the two-particle action integrals, have an uncertainty $O())$, and use the narrow ness of the initial wavepackets to linearize the one-particle actions in $y_{i} \quad r_{j}(i=1 ;::: 4$; $j=1 ; 2)$. W e consider the weak coupling regim $e$, where the one-particle actions vary faster than their tw o-particle counterpart. W e thus perform a stationary phase approxim ation on the $S$ 's to get the sem iclassical reduced density $m$ atrix as

$$
\begin{aligned}
& { }_{1}(x ; y ; t)=\left(4^{2}\right)^{d} \quad \exp \left[i f S_{s}\left(r_{1} ; x ; t\right) \quad S_{1}\left(r_{1} ; y ; t\right) g\right]
\end{aligned}
$$

$$
\begin{align*}
& s^{0}  \tag{2}\\
& M_{s ; s^{0}}=C_{s ; s^{0}}^{1=2} \exp \left[\frac { i } { 2 } \left(\begin{array}{ll}
s & \left.\left.s^{0}\right)\right] \exp \left[\frac{2}{2} f\left(p_{s} \quad p_{0}\right)^{2}+\left(p_{s^{0}} \quad p_{0}\right)^{2} g\right]: ~
\end{array}\right.\right.
\end{align*}
$$

It is straightforw ard to see that $\operatorname{Tr}[1(t)]=1$ and ${ }_{1}(x ; y ; t)=[1(y ; x ; t)]$, as required. Enforcing a further stationary phase condition on Eq. (2,i) am ounts to perform ing an average over di erent in itial conditions $r_{1 ; 2}$. It results in $s=s^{0}$, $x=y$, and thush $h_{1}(x ; y ; t) i=x_{x y}=($ is the system 's volum e), i.e. only diagonalelem ents of the reduced density $m$ atrix have a nonvanishing average (the ergodicity of $h_{1}(x ; x ; t) i$ is due to the average over initial conditions). For each initial condition, 1 has how ever nonvanishing o-diagonalm atrix elem ents, $w$ th a zero-centered distribution whose variance is given by $h_{1}(x ; y ; t)_{1}(y ; x ; t) i$. Squaring Eq. ( $(2,1)$, averaging over $r_{1 ; 2}$ and enforcing a stationary phase approxim ation on the $S$ 's, one gets

$$
\begin{align*}
& F=\exp \left[i f S_{s ; s^{0}}\left(r_{1} ; x ; r_{2} ; r ; t\right) \quad S_{1 ; s^{0}}\left(r_{1} ; y ; r_{2} ; r ; t\right) g\right] \exp \left[i f S_{l ; m}\left(r_{1} ; y ; r_{2} ; r^{0} ; t\right) \quad S_{s, m}\left(r_{1} ; x ; r_{2} ; r^{0} ; t\right) g\right]: \tag{4}
\end{align*}
$$

O ur analysis of Eqs. ( particular paths for wích $r=r^{0}$ and $s^{0}=m$, accum ulate no phase ( $F=1$ ) and thus have to be considered separately. On average, their contribution does not depend on $x$ nor $y$, and decays in tim enly because of their decreasing $m$ easure $w$ ith respect to all the paths $w$ ith $r \& r^{0}$. Their average contribution is given by
$T$ his is obtained by taking halfofthe C's in the M 's as Jacobians for the coordinate transform ation from r's to $p$ 's, and replacing the other halfby the large tim e lim it [1] $\left.{ }_{-1}^{-1}\right] C_{s, m} \quad C_{s}^{(1)} C_{m}^{(2)} /\left(t_{0}=t\right)^{2}$ for regular, and $\quad \exp \left[\quad\left(1+2_{2}\right) t\right.$, for chaotic system s (In Eq. (5్ర1) , we explicitely w rote particle indices; in our case where the tw o particles are sub jected to the sam eH am iltonian, the Lyapunov exponents are equal, $1=2$ ). Two facts are notioeable here: these contributions do not depend on the interaction strength, m oreover, Eq. (5ָ1) gives a low er bound for the decay of hj 1 fi.
$T$ he second, generic contributions to hj 1 予i decay in tim ew ith hFi. From Eq. (4i'), it is natural to expect that hF i is a decreasing function of $\dot{x} \quad y j$ and $t$ only. Sum $s$ and integrals in Eq. ${ }^{(1)(\$)}$ can then be perform ed separately to get $h_{1}(x ; y ; t)_{1}(y ; x ; t) i={ }_{0}^{2}(t)+h F(x ; y ; t) i={ }^{2}$, with

$$
Z_{t}
$$

$$
\begin{align*}
& h F(x ; y ; t) i=\exp \quad 2 Z_{Z^{0}} d t_{1} d t_{2} h U\left(q_{s}\left(t_{1}\right) ; q_{s^{0}}\left(t_{1}\right)\right) U\left(q_{s}\left(t_{2}\right) ; q_{s^{0}}\left(t_{2}\right)\right) i \\
& \exp +2 \quad d t_{1} d t_{2} h U\left(q_{s}\left(t_{1}\right) ; q_{s^{0}}\left(t_{1}\right)\right) U\left(q_{1}\left(t_{2}\right) ; q_{s^{0}}\left(t_{2}\right)\right) i: \tag{6}
\end{align*}
$$

The behavior of $\mathrm{F}(\mathrm{x} ; \mathrm{y} ; \mathrm{t}) \mathrm{i}$ sensitively depends on the distance $\mathrm{x} \quad \mathrm{y} j$ betw een the endpoints of the classicaltra jectories $q_{s}(t)$ and $q_{1}(t)$ connecting $r_{1}$ to $x$ and $y$ respectively. For $s m$ all $\dot{x} \quad y j$ the second line on the right-hand side of Eq. ( $\bar{G}$ ) alm ost com pensates the rst one [20 $0_{1}^{\prime}$ ], and a Taylor expansion of the di erence of the two-particle action integrals in Eq. (4, $\underline{4}_{1}^{1}$ ) gives in low est order

$$
h F(\dot{x} \quad y j \quad ; t) i=\exp ^{4} 2_{;=1}^{X^{d}}(x \quad y)(x \quad y){ }_{0}^{\mathrm{X}^{\mathrm{x}}} d t_{1} d t_{2} h @^{(s)} U\left(q_{s}\left(t_{1}\right) ; q_{s^{0}}\left(t_{1}\right)\right) @^{(s)} U\left(q_{s}\left(t_{2}\right) ; q_{s^{0}}\left(t_{2}\right)\right) i^{5}:(7)
$$

The reduced density m atrix has a Gaussian decay aw ay from the diagonal, which we expect to hold for ix y j (the distance over which the tw o term s in Eq. (G) alm ost cancel each other), and for short enough tim es $t<$ (after which very di erent, uncorrelated classical path's land $s m$ ay still reach tw $o$ neighboring endpoints). A $n$ estim ate for
is given by the time it takes for two initial conditions w ithin a distance (this is the uncertainty in $r_{1}$ ) to m ove aw ay a distance / from each other. In a chaotic system, this is the Ehrenfest time $=1_{1}{ }^{1} \ln (=)$, while in a regular system, is much longer, $=O([=])$ [ $\left.\overline{1} \underline{g}_{1}^{\prime}\right]$. At larger distances, $\dot{x} \quad \mathrm{yj}, \mathrm{hF}$ i is given by the rst term on the right-hand side of Eq. (G). N ote that, because the four classical paths in that term com $e$ in two pairs, the dependence on jx y jvanishes.
$T$ his concludes our sem iclassical calculation of the reduced density $m$ atrix for interacting tw o-particle system $s$. We have leamed that the variance of o -diagonalm atrix elem ents of 1 is determ ined by classical correlators, w ith the im portant caveat that they are bound dow nw ard by the expressions given in Eq. $\overline{S N}^{5}$ ). For the rest of the discussion, we note that, provided the correlators in Eqs. ( $\overline{\operatorname{G}})$ and ( $(\overline{1})$ ) decay faster than $/ \bar{J}_{1}^{-} \hbar^{1} j^{1}$, the 0 -diagonalm atrix elem ents exhibit a dom inant exponential decay in tim e. This condition is rather nonrestrictive and is surely satis ed in a chaotic system. W e therefore assum efrom now on a fast decay of the correlations,

$$
\begin{align*}
h U\left(q_{s}\left(t_{1}\right) ; q_{s^{0}}\left(t_{1}\right)\right) U\left(q_{s}\left(t_{2}\right) ; q_{s^{0}}\left(t_{2}\right)\right) i= & \left(t_{1} \quad t_{2}\right) ;  \tag{8}\\
h^{(s)} U\left(q_{s}\left(t_{1}\right) ; q_{s^{0}}\left(t_{1}\right)\right) @^{(s)} U\left(q_{s}\left(t_{2}\right) ; q_{s^{0}}\left(t_{2}\right)\right) i= & ; \quad\left(t_{1} \quad \frac{t}{2}\right): \tag{9}
\end{align*}
$$

Rntanglem ent is quanti ed by the purity $P(t)=$ $d x d y h{ }_{1}(x ; y ; t){ }_{1}\left(\underline{y} ; x_{1} ; t\right) i_{1}$ which is straightforw ard to com pute from Eqs. $(1, W)$ e get three distinct regim es of decay: (i) an intitial regim e of classical relaxation for $t<$. During that time, 1 evolves from a pure, but localized ${ }_{1}(0)=j_{1}{ }_{1}$ ihr $r_{1} j$ to a less localized, but still al$m$ ost pure $1(t)$, w ith an algebraic purity decay obtained
 (even in the case of a correlator (9) saturating at a nite value for $\mathrm{t}_{1} \hbar_{\mathrm{t}} j!1$, which $m$ ay occur in regular system $s$, this in itial decay $w$ ill still be algebraic / $t^{d}$ ); (ii) a regim ewhere quantum coherence develops betw een the two particles so that 1 becom es a mixture. From
 $P(t)^{\prime} \exp [m$ in $(2 ; 1+2) t]$ in a chaotic system; in a regular system one hasP ( t$) /\left(\mathrm{t}_{0}=\mathrm{t}\right)^{2}$, since ${ }_{0}^{2}(\mathrm{t})$ dom inates the decay of $P(t)$ independently of the correlators in Eqs. $\left(\overline{\underline{g}}\left(\frac{\overline{1}}{1-\overline{1}}\right)\right.$ ) and (iii) a saturation regim e where the purity reaches its $m$ in m al value. In the chaotic lim it, this saturation value can be estim ated using a RM T approach as $P(1)=2\left({ }^{d}=\right)+O\left({ }^{2}\right)$ [2] $]$, which is in qualitative agreem ent w ith the results obtained in Ref. $\bar{F}_{1}^{1}$ ] for the von $N$ eum ann entropy. There is no reason to expect a universal saturation value in the regular regim e.

A nalyzing these results, we note that Eqs. (G) and $\left(\overline{7}\right.$, ) are rem iniscent of the results obtained for $P^{-}(t)$ by perturbative treatm ents in Refs. $\left[\bar{G}_{1}, \overline{1}_{1}\right]$, but they apply well beyond the linear response regim e. O ur weak coupling condition that the one-particle actions $S$ vary faster than the two-particle actions $S$ roughly gives an upper bound $U \quad E$ for the typical interaction strength $U \quad(E$ is the one-particle energy). The linear response regin e is how ever restricted by a m uch $m$ ore stringent condition $\mathrm{U} \quad \mathrm{E}$ ( is the $m$ ean level spacing) $[16]]_{r}^{1}$ The decay regim e (ii) of $P$ ( $($ )_reconciles the a priori contradicting claim sofR efs. [3]n, [1] pling, the decay of $P(t)$ is given by classical correlators, and thus depends on the interaction strength, in agree$m$ ent with Ref. [G]. H ow ever, $P$ ( $t$ ) cannot decay faster than the bound given in Eq. $\left.\overline{(F}_{1}^{\prime \prime}\right)$, so that at stronger coupling, and in the chaotic regim e, one recovers the results of Ref. [4] $\left[_{1}^{1}\right.$. Sim ultaneously, regim e (ii) also explains the data in $\bar{F}$ ig. 2 and 4 of Ref. [1] 1 , show ing an exponential
decay ofP ( t ) in the chaotic regim $e$, and a power-law decay w ith an exponent close to 2 in the regular regim e (th is pow er-law decay was left unexplained by the authors of Ref. [ $\left[_{1}\right]$ ). O ur sem iclassical treatm ent thus presents a uni ed picture of the problem.

Three $m$ ore rem arks are in order here. First the stationary phase solutions leading to the above results still hold in the case when the tw o particles are sub jected to di erent one-particle H am iltonians. Second, the pow erlaw decay ofP ( $t$ ) predicted above for regular system $s$, is to be taken as an average over in intial conditions $r_{1 ; 2}$ (in that respect see Refs. [14] and [24]), but $m$ ay also hold for individual initial conditions, às e.g. in $\bar{T}]$. Finally,
 exponentially in tim ew ith a rate related to the spectrum of Lyapunov exponents. This also $m$ ay induce a dependence of $P$ ( $t$ ) on the Lyapunov exponents, which can be captured by the linear response approach of $R$ ef. [G] $]$. W e note how ever that this is not a generic situation, as m ost fully chaotic, but nonhyperbolic system s have pow er-law decaying correlations.

A s a concluding line, and noting sim ilarities betw een the problem treated here and that of decoherence by an environm ent [ [1] $\left.0_{1}^{1}\right]$, we anticipate that a sem iclassical approach as the one presented here (see also R ef. [2] ['] ${ }_{1}$ ]) could clarify how decoherence relates to the intrinsic dynam ics of the system $[1], 2 \overline{2}]$ ].
