#### Abstract

A. E. Allahverdyan and Th . M. Nieuwenhuizen [1] in their paper "A mathematical theorem as a basis for the second law: Thomson's formulation applied to equilibrium" present a proof of the second law of thermodynamics based on quantum mechanics. In this comment on their paper I offer a counterexample to their proof.

In their paper [1] A. E. Allahverdyan and Th . M. Nieuwenhuizen present a proof of the second law of thermodynamics as a rigorous theorem of quantum mechanics. Allahverdyan and Nieuwenhuizen consider a closed statistical system . At $t=0$ the initial Hamiltonian is $\hat{\mathrm{H}}_{0}$ and the initial equilibrium state is a Gibbs distribution so that,

$$
\begin{equation*}
\hat{\rho}(0)=\frac{e^{-\beta \hat{H}_{0}}}{Z} ; \quad Z=\operatorname{tre}^{-\beta \hat{H}_{0}} \tag{1}
\end{equation*}
$$

where $\beta=1 / \mathrm{T}$ and T is the temperature. At time $\mathrm{t}=0$ an external interaction is turned on and then turned off at time t . W is the work put into the system during this interaction and is given by [1],

$$
\begin{equation*}
\mathrm{W}=\operatorname{tr}\left[\hat{\mathrm{H}}_{0} \hat{\mathrm{~V}} \hat{\rho}(0) \hat{\mathrm{V}}^{\dagger}\right]-\operatorname{tr}\left[\hat{\mathrm{H}}_{0} \hat{\rho}(0)\right] \tag{2}
\end{equation*}
$$

where $\hat{\mathrm{V}}$ is a unitary operator that describes the interaction. Using the mathematical identity $\operatorname{tr}[\mathrm{AB}]=\operatorname{tr}[\mathrm{BA}]$ this can be rewritten as,

$$
\begin{equation*}
\mathrm{W}=\operatorname{tr}\left[\hat{\mathrm{V}}^{\dagger} \hat{\mathrm{H}}_{0} \hat{\mathrm{~V}} \hat{\rho}(0)\right]-\operatorname{tr}\left[\hat{\mathrm{H}}_{0} \hat{\rho}(0)\right] \tag{3}
\end{equation*}
$$

Allahverdyan and Nieuwenhuizen claim that W must be non-negative for all possible interactions. Since the interaction is described by $\hat{V}$ this means that W must be non-negative for all possible unitary operators $\hat{V}$. I will give an example where this is not the case.

I will examine this problem for a quantized fermion field interacting with a quantized electromagnetic field in the temporal gauge. In the temporal gauge the gauge condition is given by the relationship $\mathrm{A}_{0}=0[2,3,4,5]$ where $\mathrm{A}_{0}$ is the scalar component of the electric potential. We will work in the Schrödinger picture and use natural units so
that $\hbar=\mathrm{c}=1$. In the Schrödinger picture the field operators are time independent and the time dependence of the quantum system is reflected in the state vectors $|\Omega(t)\rangle$. The Hamiltonian is given by,

$$
\begin{equation*}
\hat{\mathrm{H}}_{0}=\hat{\mathrm{H}}_{0, \mathrm{D}}+\hat{\mathrm{H}}_{0, \mathrm{M}}-\int \hat{\mathbf{J}}(\mathbf{x}) \cdot \hat{\mathbf{A}}(\mathbf{x}) \mathrm{d} \mathbf{x} \tag{4}
\end{equation*}
$$

where,

$$
\begin{align*}
& \hat{\mathrm{H}}_{0, \mathrm{D}}=\frac{1}{2} \int\left[\hat{\Psi}^{\dagger}(\mathbf{x}), \mathrm{H}_{0, \mathrm{D}} \hat{\psi}(\mathbf{x})\right] \mathrm{d} \mathbf{x} ; \mathrm{H}_{0, \mathrm{D}}=-\mathrm{i} \boldsymbol{\alpha} \cdot \nabla+\beta \mathrm{m}  \tag{5}\\
& \hat{\mathrm{H}}_{0, \mathrm{M}}=\frac{1}{2} \int\left(\hat{\mathbf{E}}^{2}+\hat{\mathbf{B}}^{2}\right) \mathrm{d} \mathbf{x} ; \quad \hat{\mathbf{B}}(\mathbf{x})=\nabla \times \hat{\mathbf{A}}(\mathbf{x})  \tag{6}\\
& \hat{\mathbf{J}}(\mathbf{x})=\frac{\mathrm{q}}{2}\left[\hat{\Psi}^{\dagger}(\mathbf{x}), \boldsymbol{\alpha} \hat{\psi}(\mathbf{x})\right] \tag{7}
\end{align*}
$$

In the above expressions m is the fermion mass, $\boldsymbol{\alpha}$ and $\beta$ are the usual 4 x 4 matrices, q is the electric charge, $\hat{\mathrm{H}}_{0, \mathrm{D}}$ is the Dirac Hamiltonian, $\hat{\mathrm{H}}_{0, \mathrm{M}}$ is the Hamiltonian for the electromagnetic field, and $\hat{\mathbf{J}}(\mathbf{x})$ is the current operator. The Schrödinger picture time independent fermion field operators are $\hat{\psi}(\mathbf{x})$ and $\hat{\psi}^{\dagger}(\mathbf{x})$. The Schrödinger picture time independent field operators for the electromagnetic field are $\hat{\mathbf{A}}(\mathbf{x})$ and $\hat{\mathbf{E}}(\mathbf{x})$. The electromagnetic field operators are real so that $\hat{\mathbf{A}}^{\dagger}(\mathbf{x})=\hat{\mathbf{A}}(\mathbf{x})$ and $\hat{\mathbf{E}}^{\dagger}(\mathbf{x})=\hat{\mathbf{E}}(\mathbf{x})$.

The field operators obey the following relationships [3,4],

$$
\begin{equation*}
\left[\hat{\mathrm{A}}^{\mathrm{i}}(\mathbf{x}), \hat{\mathrm{E}}^{\mathrm{j}}(\mathbf{y})\right]=-\mathrm{i} \delta_{\mathrm{ij}} \delta^{3}(\mathbf{x}-\mathbf{y}) ;\left[\hat{\mathrm{A}}^{\mathrm{i}}(\mathbf{x}), \hat{\mathrm{A}}^{\mathrm{j}}(\mathbf{y})\right]=\left[\hat{\mathrm{E}}^{\mathrm{i}}(\mathbf{x}), \hat{\mathrm{E}}^{\mathrm{j}}(\mathbf{y})\right]=0 \tag{8}
\end{equation*}
$$

and

$$
\begin{equation*}
\left\{\hat{\psi}_{\mathrm{a}}^{\dagger}(\mathbf{x}), \hat{\psi}_{\mathrm{b}}(\mathbf{y})\right\}=\delta_{\mathrm{ab}} \delta(\mathbf{x}-\mathbf{y}) ;\left\{\hat{\Psi}_{\mathrm{a}}^{\dagger}(\mathbf{x}), \hat{\psi}_{\mathrm{b}}^{\dagger}(\mathbf{y})\right\}=\left\{\hat{\Psi}_{\mathrm{a}}(\mathbf{x}), \hat{\psi}_{\mathrm{b}}(\mathbf{y})\right\}=0 \tag{9}
\end{equation*}
$$

where "a" and "b" are spinor indices. In addition, all commutators between the electromagnetic field operators and fermion field operators are zero, i.e.,

$$
\begin{equation*}
[\hat{\mathbf{A}}(\mathbf{x}), \hat{\psi}(\mathbf{y})]=[\hat{\mathbf{E}}(\mathbf{x}), \hat{\psi}(\mathbf{y})]=\left[\hat{\mathbf{A}}(\mathbf{x}), \hat{\psi}^{\dagger}(\mathbf{y})\right]=\left[\hat{\mathbf{E}}(\mathbf{x}), \hat{\psi}^{\dagger}(\mathbf{y})\right]=0 \tag{10}
\end{equation*}
$$

Define the quantity,

$$
\begin{equation*}
\hat{\mathrm{G}}(\mathbf{x})=\nabla \cdot \hat{\mathbf{E}}(\mathbf{x})-\hat{\rho}(\mathbf{x}) \tag{11}
\end{equation*}
$$

where the current operator $\hat{\rho}(\mathbf{x})$ is defined by,

$$
\begin{equation*}
\hat{\rho}(\mathbf{x})=\frac{\mathrm{q}}{2}\left[\hat{\psi}^{\dagger}(\mathbf{x}), \hat{\psi}(\mathbf{x})\right] \tag{12}
\end{equation*}
$$

All valid state vectors $|\Omega\rangle$ must satisfy the Gauss constraint [2],

$$
\begin{equation*}
\hat{\mathrm{G}}(\mathbf{x})|\Omega\rangle=0 \tag{13}
\end{equation*}
$$

The unitary operator $\hat{\mathrm{V}}$ converts the state vector $|\Omega\rangle$ into the state vector $\hat{\mathrm{V}}|\Omega\rangle$. The Gauss constraint must be still be satisfied so that in the temporal gauge $\hat{\mathrm{V}}$ is restricted to those operators which satisfy,

$$
\begin{equation*}
\hat{\mathrm{G}}(\mathbf{x}) \hat{\mathrm{V}}|\Omega\rangle=0 \text { for all }|\Omega\rangle \text { for which } \hat{\mathrm{G}}(\mathbf{x})|\Omega\rangle=0 \tag{14}
\end{equation*}
$$

I will show that for the Hamiltonian operator defined in (4) it is possible to find a unitary operator $\hat{\mathrm{V}}$ which satisfies the Gauss constraint for which W of equation (3) is negative. This is contrary to the assertion of reference [1].

Now let,

$$
\begin{equation*}
\hat{\mathrm{V}}=\hat{\mathrm{U}} \hat{\mathrm{R}} \tag{15}
\end{equation*}
$$

where $\hat{U}$ and $\hat{R}$ are unitary operators. Let $\hat{U}$ satisfy the Gauss constraint (14) and define $\hat{R}$ by,

$$
\begin{equation*}
\hat{\mathrm{R}}=\mathrm{e}^{\mathrm{i} \hat{U}^{\dagger} \hat{C} \hat{U}} \tag{16}
\end{equation*}
$$

where

$$
\begin{equation*}
\hat{\mathrm{C}}=\int \hat{\mathbf{E}} \cdot \nabla \chi \mathrm{d} \mathbf{x} \tag{17}
\end{equation*}
$$

where $\chi(\overrightarrow{\mathrm{x}})$ is an arbitrary real valued function. Note that $\hat{\mathrm{C}}=\hat{\mathrm{C}}^{\dagger}$ so that $\hat{\mathrm{R}}^{\dagger}=\mathrm{e}^{-\mathrm{i} \hat{U}^{\dagger} \hat{C} \hat{U}}$ therefore $\hat{\mathrm{R}}^{\dagger} \hat{\mathrm{R}}=1$ so that $\hat{\mathrm{R}}$ is unitary.

Using the commutator relations we obtain,

$$
\begin{equation*}
\left[\hat{\mathrm{H}}_{0, \mathrm{D}}, \hat{\mathrm{C}}\right]=[\hat{\mathbf{J}}(\mathbf{x}), \hat{\mathrm{C}}]=[\rho(\mathbf{x}), \hat{\mathrm{C}}]=0 \tag{18}
\end{equation*}
$$

and,

$$
\begin{equation*}
[\hat{\mathbf{A}}(\mathbf{x}), \hat{\mathrm{C}}]=-\mathrm{i} \nabla \chi(\mathbf{x}) \tag{19}
\end{equation*}
$$

Use this result to obtain,

$$
\begin{equation*}
[\hat{\mathbf{B}}(\mathbf{x}), \hat{\mathrm{C}}]=\nabla \times[\hat{\mathbf{A}}(\mathbf{x}), \hat{\mathrm{C}}]=-\mathrm{i} \nabla \times \nabla \chi(\mathbf{x})=0 \tag{20}
\end{equation*}
$$

Therefore,

$$
\begin{equation*}
\left[\hat{\mathrm{H}}_{0, \mathrm{M}}, \hat{\mathrm{C}}\right]=0 \tag{21}
\end{equation*}
$$

From the above we obtain,

$$
\begin{equation*}
[\hat{\mathrm{G}}(\mathbf{x}), \hat{\mathrm{C}}]=0 \tag{22}
\end{equation*}
$$

Next we want to determine if $\hat{V}=\hat{U} \hat{R}$ satisfies the Gauss constraint. To do this we use the obvious relationship,

$$
\begin{equation*}
\left[\hat{\mathrm{U}}^{\dagger} \hat{\mathrm{O}}_{1} \hat{\mathrm{U}}, \hat{\mathrm{U}}^{\dagger} \hat{\mathrm{O}}_{2} \hat{\mathrm{U}}\right]=\hat{\mathrm{U}}^{\dagger}\left[\hat{\mathrm{O}}_{1}, \hat{\mathrm{O}}_{2}\right] \hat{\mathrm{U}} \tag{23}
\end{equation*}
$$

where $\hat{\mathrm{O}}_{1}$ and $\hat{\mathrm{O}}_{2}$ are operators. Use this in (22) to obtain,

$$
\begin{equation*}
\left[\hat{\mathrm{U}}^{\dagger} \hat{\mathrm{G}}(\mathbf{x}) \hat{\mathrm{U}}, \hat{\mathrm{U}}^{\dagger} \hat{\mathrm{C}} \hat{\mathrm{U}}\right]=\hat{\mathrm{U}}^{\dagger}[\hat{\mathrm{G}}(\mathbf{x}), \hat{\mathrm{C}}] \hat{\mathrm{U}}=0 \tag{24}
\end{equation*}
$$

Therefore $\hat{V}=\hat{U} \hat{R}$ satisfied Gauss constraint since $\hat{U}$ has been assumed to satisfy this constraint and $\hat{U}^{\dagger} \hat{C} \hat{U}$, and thereby $\hat{R}$, commutes with $\hat{U}^{\dagger} \hat{G}(\mathbf{x}) \hat{U}$.

Next we want to evaluate $\hat{\mathrm{V}}^{\dagger} \hat{\mathrm{H}}_{0} \hat{\mathrm{~V}}$. Use (4) to obtain,

$$
\begin{equation*}
\hat{\mathrm{V}}^{\dagger} \hat{\mathrm{H}}_{0} \hat{\mathrm{~V}}=\hat{\mathrm{V}}^{\dagger}\left(\hat{\mathrm{H}}_{0, \mathrm{D}}+\hat{\mathrm{H}}_{0, \mathrm{M}}-\int \hat{\mathbf{J}}(\mathbf{x}) \cdot \hat{\mathbf{A}}(\mathbf{x}) \mathrm{d} \mathbf{x}\right) \hat{\mathrm{V}} \tag{25}
\end{equation*}
$$

We will require the Baker-Campell-Hausdorff relationships [6] which states that,

$$
\begin{equation*}
\mathrm{e}^{+\hat{\mathrm{O}}_{1}} \hat{\mathrm{O}}_{2} \mathrm{e}^{-\hat{\mathrm{O}}_{1}}=\hat{\mathrm{O}}_{2}+\left[\hat{\mathrm{O}}_{1}, \hat{\mathrm{O}}_{2}\right]+\frac{1}{2}\left[\hat{\mathrm{O}}_{1},\left[\hat{\mathrm{O}}_{1}, \hat{\mathrm{O}}_{2}\right]\right]+\ldots \tag{26}
\end{equation*}
$$

Use this along with (18), (21), and (24) to obtain,

$$
\begin{equation*}
\hat{\mathrm{V}}^{\dagger}\left(\hat{\mathrm{H}}_{0, \mathrm{D}}+\hat{\mathrm{H}}_{0, \mathrm{M}}\right) \hat{\mathrm{V}}=\hat{U}^{\dagger}\left(\hat{\mathrm{H}}_{0, \mathrm{D}}+\hat{\mathrm{H}}_{0, \mathrm{M}}\right) \hat{\mathrm{U}} \tag{27}
\end{equation*}
$$

Next we obtain,

$$
\begin{equation*}
\hat{\mathrm{V}}^{\dagger}(\hat{\mathbf{J}}(\mathbf{x}) \cdot \hat{\mathbf{A}}(\mathbf{x})) \hat{\mathrm{V}}=\left(\hat{\mathrm{V}}^{\dagger} \hat{\mathbf{J}}(\mathbf{x}) \hat{\mathrm{V}}\right) \cdot\left(\hat{\mathrm{V}}^{\dagger} \hat{\mathbf{A}}(\mathbf{x}) \hat{\mathrm{V}}\right) \tag{28}
\end{equation*}
$$

Use (10), (19), (24), and (26) to yield,

$$
\begin{equation*}
\left(\hat{\mathrm{V}}^{\dagger} \hat{\mathbf{J}}(\mathbf{x}) \hat{\mathrm{V}}\right)=\left(\hat{\mathrm{U}}^{\dagger} \hat{\mathbf{J}}(\mathbf{x}) \hat{\mathrm{U}}\right) \tag{29}
\end{equation*}
$$

and,

$$
\begin{equation*}
\left(\hat{\mathrm{V}}^{\dagger} \hat{\mathbf{A}}(\mathbf{x}) \hat{\mathrm{V}}\right)=\hat{\mathrm{U}}^{\dagger}(\hat{\mathbf{A}}(\mathbf{x})-\nabla \chi(\mathbf{x})) \hat{\mathrm{U}} \tag{30}
\end{equation*}
$$

Use these results in (28) to obtain

$$
\begin{align*}
\hat{\mathrm{V}}^{\dagger}(\hat{\mathbf{J}}(\mathbf{x}) \cdot \hat{\mathbf{A}}(\mathbf{x})) \hat{\mathrm{V}} & =\left(\hat{U}^{\dagger} \hat{\mathbf{J}}(\mathbf{x}) \hat{\mathrm{U}}\right) \cdot \hat{\mathrm{U}}^{\dagger}(\hat{\mathbf{A}}(\mathbf{x})-\nabla \chi(\mathbf{x})) \hat{\mathrm{U}} \\
& =\hat{\mathrm{U}}^{\dagger}(\hat{\mathbf{J}}(\mathbf{x}) \cdot(\hat{\mathbf{A}}(\mathbf{x})-\nabla \chi(\mathbf{x}))) \hat{\mathrm{U}} \tag{31}
\end{align*}
$$

Use this and (27) in (25) to obtain,

$$
\begin{equation*}
\mathrm{V}^{\dagger} \hat{\mathrm{H}}_{0} \mathrm{~V}=\hat{\mathrm{U}}^{\dagger}\left(\hat{\mathrm{H}}_{0}-\int \hat{\mathbf{J}}(\mathbf{x}) \cdot \nabla \chi(\mathbf{x}) \mathrm{d} \mathbf{x}\right) \hat{\mathrm{U}} \tag{32}
\end{equation*}
$$

Use this in (3) to yield,

$$
\begin{equation*}
\mathrm{W}=\mathrm{W}_{0}-\int \operatorname{tr}\left[\hat{\mathrm{U}}^{\dagger} \hat{\mathbf{J}}(\mathbf{x}) \hat{\mathrm{U}} \hat{\rho}(0)\right] \cdot \nabla \chi(\mathbf{x}) \mathrm{d} \mathbf{x} \tag{33}
\end{equation*}
$$

where,

$$
\begin{equation*}
\mathrm{W}_{0}=\operatorname{tr}\left[\hat{\mathrm{U}}^{\dagger} \hat{\mathrm{H}}_{0} \hat{\mathrm{U}} \hat{\rho}(0)\right]-\operatorname{tr}\left[\hat{\mathrm{H}}_{0} \hat{\rho}(0)\right] \tag{34}
\end{equation*}
$$

Integrate the second term in (33) with respect to parts and assume reasonable boundary conditions to obtain,

$$
\begin{equation*}
\mathrm{W}=\mathrm{W}_{0}+\int \chi(\mathbf{x}) \nabla \cdot \hat{\mathbf{J}}_{\hat{\mathrm{U}}}(\mathbf{x}) \mathrm{d} \mathbf{x} \tag{35}
\end{equation*}
$$

where $\hat{\mathbf{J}}_{\hat{\mathrm{U}}}(\mathbf{x})$ is defined by,

$$
\begin{equation*}
\hat{\mathbf{J}}_{\hat{\mathrm{U}}}(\mathbf{x})=\operatorname{tr}\left[\hat{U}^{\dagger} \hat{\mathbf{J}}(\mathbf{x}) \hat{\mathrm{U}} \hat{\rho}(0)\right] \tag{36}
\end{equation*}
$$

Note that $\mathrm{W}_{0}$ and the quantity $\hat{\mathbf{J}}_{\hat{\mathrm{U}}}(\mathbf{x})$ are independent of $\chi(\mathbf{x})$. Therefore $\chi(\mathbf{x})$ can be varied in an arbitrary manner without affecting $\mathrm{W}_{0}$ or $\hat{\mathbf{J}}_{\hat{U}}(\mathbf{x})$. Assume that $\hat{U}$ is chosen so that $\nabla \cdot \hat{\mathbf{J}}_{\hat{\mathrm{U}}}(\mathbf{x})$ is non-zero. In this case we can always find a $\chi(\mathbf{x})$ which makes W a negative number. For example let $\chi(\mathbf{x})=-\lambda \nabla \cdot \hat{\mathbf{J}}_{\hat{\mathrm{U}}}(\mathbf{x})$ where $\lambda$ is a constant. In this case (35) becomes,

$$
\begin{equation*}
\mathrm{W}=\mathrm{W}_{0}-\lambda \int\left(\nabla \cdot \hat{\mathbf{J}}_{\hat{\mathrm{U}}}(\mathbf{x})\right)^{2} \mathrm{~d} \mathbf{x} \tag{37}
\end{equation*}
$$

Therefore, since $\nabla \cdot \hat{\mathbf{J}}_{\hat{\mathrm{U}}}(\mathbf{x})$ is non-zero the quantity under the integral must be positive. Therefore for sufficiently large $\lambda$ the work W will be negative.

This result depends on the assumption that we can find a unitary transformation $\hat{\mathrm{U}}$ such that $\nabla \cdot \hat{\mathbf{J}}_{\hat{\mathrm{U}}}(\mathbf{x})$ is non-zero. How do we know that this can be done? $\hat{\mathbf{J}}_{\hat{\mathrm{U}}}(\mathbf{x})$ is the current averaged over the distribution after an interaction associated with the unitary operator $\hat{U}$. Therefore we must have an interaction the takes the average current from an initial equilibrium state, where the divergence of the average current is zero, to some nonequilibrium state where $\nabla \cdot \hat{\mathbf{J}}_{\hat{\mathrm{U}}}(\mathbf{x})$ is non-zero. Since there are many interaction that can take a system into a non-equilibrium state it is reasonable to assume that a $\hat{U}$ exists.

In conclusion a counterexample has been found to the proof presented in [1] that the quantity W in equation (2) must be non-negative for any unitary operator $\hat{\mathrm{V}}$. The counterexample is for a quantized fermion field coupled to a quantized electromagnetic field in the temporal gauge. It is shown that in this case a unitary operator $\hat{\mathrm{V}}$ exists for which W is negative.
