## Abstract

Inspired by works on information transmission through quantum channels, we propose the use of a couple of mutual entropies to quantify the efficiency of continual measurement schemes in extracting information on the measured quantum system. Properties of these measures of information are studied and bounds on them are derived.

## 1 Quantum measurements and entropies

We speak of quantum continual measurements when a quantum system is taken under observation with continuity in time and the output is not a single random variable, but rather a stochastic process [1, 2]. The aim of this paper is to quantify, by means of entropic quantities, the effectiveness of a continual measurement in extracting information from the underlying quantum system.

Various types of entropies and bounds on informational quantities can be introduced and studied in connection with continual measurements [3–5]. In particular, in Ref. [5] the point of view was the one of information transmission: the quantum system is a channel in which some information is encoded at an initial time; the continual measurement represents the decoding apparatus. In this paper, instead, we consider the quantum system in itself, not as a transmission channel, and we propose and study a couple of mutual entropies giving two indexes of how good is the continual measurement in extracting information about the quantum system.

### 1.1 Algebras, states, entropies

From now on  $\mathcal{H}$  will be a separable complex Hilbert space, the space where our quantum system lives.

### 1.1.1 Von Neumann algebras and normal states

A normal state on  $L(H)$  (bounded linear operators on  $H$ ) is identified with a statistical operator,  $T(H)$  and  $S(H) = T(H)$  are the trace-class and the space of the statistical operators on  $H$ , respectively.

Let  $(\Omega; \mathcal{F}; Q)$  be a measure space, where  $Q$  is a  $\sigma$ -finite measure. We consider the  $W^*$ -algebras  $L^1(\Omega; \mathcal{F}; Q)$  and  $L^\infty(\Omega; \mathcal{F}; Q; L(H))' \subset L^1(\Omega; \mathcal{F}; Q; L(H))$ . Let us note that a normal state on  $L^1(\Omega; \mathcal{F}; Q)$  is a probability density with respect to  $Q$ , while a normal state on  $L^1(\Omega; \mathcal{F}; Q; L(H))$  is a measurable function  $f: \Omega \rightarrow \mathbb{R}$  such that  $\text{Tr} f(\cdot)g$  is a probability density with respect to  $Q$ .

### 1.1.2 Relative entropy

The general definition of the relative entropy  $S(\rho \parallel \sigma)$  for two states  $\rho$  and  $\sigma$  is given in [6]; here we give only some particular cases of the general definition.

Let us consider two quantum states  $\rho, \sigma \in S(H)$  and two classical states  $q_k$  on  $L^1(\Omega; \mathcal{F}; Q)$  (two probability densities with respect to  $Q$ ). The von Neumann entropy, the quantum relative entropy and the classical one are

$$S_q(\rho) = -\text{Tr} \rho \ln \rho; \quad S(\rho \parallel \sigma) = \text{Tr} (\rho \ln \rho - \rho \ln \sigma); \quad (1)$$

$$S_c(q_1 \parallel q_2) = \int_\Omega Q(d\omega) q_1(\omega) \ln \frac{q_1(\omega)}{q_2(\omega)}; \quad (2)$$

Let us consider now two normal states  $\rho_k$  on  $L^1(\Omega; \mathcal{F}; Q; L(H))$  and set  $q_k(\omega) = \text{Tr} \rho_k(\omega)g$ ,  $\rho_k(\omega) = \rho_k(\omega)g_k(\omega)$  (these definitions hold where the denominators do not vanish and are completed arbitrarily where the denominators vanish). Then, the relative entropy is

$$\begin{aligned} S(\rho_1 \parallel \rho_2) &= \int_\Omega Q(d\omega) \text{Tr} \rho_1(\omega) \ln \rho_1(\omega) - \text{Tr} \rho_1(\omega) \ln \rho_2(\omega) \\ &= S_c(q_1 \parallel q_2) + \int_\Omega Q(d\omega) q_1(\omega) S_q(\rho_1(\omega) \parallel \rho_2(\omega)); \end{aligned} \quad (3)$$

We are using a subscript "c" for classical entropies, a subscript "q" for purely quantum ones and no subscript for general entropies, eventually of a mixed character. Having used the natural logarithm in these definitions, the entropies are in nats. To obtain entropies in bits one has to divide by  $\ln 2$ .

The following result is very useful ([6] Corollary 5.20 and Eq. (5.22)).

**Proposition 1.** Let  $\rho_1, \rho_2$  and  $\rho_{12}$  be normal states of the tensor product von Neumann algebra  $M_1 \otimes M_2$  and let  $\rho_i = \rho_{12}|_{M_i}$ ,  $i=1,2$ . Then,

$$\begin{aligned} S(\rho_{12} \parallel \rho_1 \otimes \rho_2) &= S(\rho_1 \parallel \rho_1) + S(\rho_{12} \parallel \rho_1 \otimes \rho_2) \\ &= S(\rho_1 \parallel \rho_1) + S(\rho_2 \parallel \rho_2) + S(\rho_{12} \parallel \rho_1 \otimes \rho_2) \end{aligned} \quad (4)$$

The quantity  $S(\rho_{12} \parallel \rho_1 \otimes \rho_2)$  is the relative entropy of a state with respect to its marginals; this is what we call mutual entropy.

## 1.2 Instruments and channels

### 1.2.1 Channels

Let  $M_1$  and  $M_2$  be two  $W^*$ -algebras. A linear map  $\phi$  from  $M_2$  to  $M_1$  is said to be a channel ([6] p. 137) if it is completely positive, unital (i.e. identity preserving) and normal (or, equivalently, weakly continuous).

Due to the equivalence [7] of  $w^*$ -continuity and existence of a predual, a channel is equivalently defined by:  $\phi$  is a norm-one, completely positive linear map from the predual  $M_1^*$  to the predual  $M_2^*$ . Let us note also that  $\phi$  maps normal states on  $M_1$  into normal states on  $M_2$ .

A key result which follows from the convexity properties of the relative entropy is Uhlmann monotonicity theorem ([6], Theor. 1.5 p. 21), which implies that channels decrease the relative entropy.

**Theorem 2.** If  $\phi$  and  $\psi$  are two normal states on  $M_1$  and  $\phi$  is a channel from  $M_1$  to  $M_2$ , then  $S(\phi(\psi)) \leq S(\psi)$ .

### 1.2.2 Instruments and POVM measures

The notion of instrument is central in quantum measurement theory; an instrument gives the probabilities and the state changes [8, 9].

Let  $(\mathcal{F}; F)$  be a measurable space. An instrument  $I$  is a map valued measure such that (i)  $I(F)$  is a completely positive, linear, bounded operator on  $\mathcal{T}(H)$ ,  $\|I(F)\| \leq 1$ , (ii)  $I(\emptyset) = 0$ , (iii) for every countable family  $\{F_i\}$  of disjoint sets in  $\mathcal{F}$  one has  $\sum_i I(F_i) = I(\bigcup_i F_i)$ ,  $\sum_i \|I(F_i)\| \leq 1$ ,  $\sum_i I(F_i) \in \mathcal{L}(H)$ .

The map  $F \mapsto I(F)$  turns out to be a positive operator valued (POV) measure (the observable associated with the instrument  $I$ ). For every  $\mu \in \mathcal{S}(H)$  the map  $F \mapsto \mu(I(F)) = \text{Tr}(\mu I(F))$  is a probability measure: the probability that the result of the measurement be in  $F$  when the pre-measurement state is  $\mu$ . Moreover, given the result  $F$ , the post-measurement state is  $\mu_F = I(F)^{-1} I(F) \mu$ .

### 1.2.3 The instrument as a channel

Given an instrument  $I$  with value space  $(\mathcal{F}; F)$  it is always possible to find a  $\sigma$ -finite measure on  $(\mathcal{F}; F)$  (or even a probability measure), such that all the probabilities  $\mu_F, \mu \in \mathcal{S}(H)$ , are absolutely continuous with respect to  $Q$ .

**Theorem 3** ([10], Theorem 2). Let  $I$  be an instrument on the trace-class of a complex separable Hilbert space  $H$  with value space  $(\mathcal{F}; F)$  and let  $Q$  be a  $\sigma$ -finite measure on  $(\mathcal{F}; F)$  such that  $\text{Tr} I(F) \leq Q(F), \forall F \in \mathcal{F}$ . Then, there exists a unique channel  $\phi_I$  from  $\mathcal{T}(H)$  into  $L^1(\mathcal{F}; Q; \mathcal{T}(H))$  such that

$$\int_{\mathcal{F}} \text{Tr}(\mu I(F)) dQ(F) = \text{Tr}(\mu \phi_I(Q)) \quad (5)$$

$$\mu \in \mathcal{S}(H); \quad \mu_F \in \mathcal{L}(H); \quad \mu_F \in L^1(\mathcal{F}; Q);$$

Viceversa, a channel  $\phi$  from  $\mathcal{T}(H)$  into  $L^1(\mathcal{F}; Q; \mathcal{T}(H))$  defines a unique instrument  $I$  by

$$I(F) = \int_{\mathcal{F}} \mu_F d\mu; \quad \mu \in \mathcal{S}(H); \quad \mu_F \in \mathcal{L}(H); \quad \mu_F \in L^1(\mathcal{F}; Q); \quad (6)$$

### 1.2.4 A posteriori states

When  $\rho \in S(H)$ , then  $\rho$  is a normal state on  $L^1(F; Q; L(H))$ . Let us normalize the positive trace-class operators  $\rho$  by setting

$$\rho = \begin{cases} (\text{Tr}_H f \rho) \rho^{-1} & \text{if } \text{Tr}_H f \rho > 0 \\ \sim \rho \in S(H), & \text{if } \text{Tr}_H f \rho = 0 \end{cases} \quad (7)$$

Then, we have

$$\int_F \rho(d!) = I(F)[\rho]; \quad \int_F \rho(d!) = I(F)[\rho]; \quad (\text{Bochner integral}): \quad (8)$$

According to Ozawa [11],  $\rho$  is a family of a posteriori states for the instrument  $I$  and the pre-measurement state  $\rho$ . The interpretation is that  $\rho$  is the state just after the measurement to be attributed to the quantum system if the result of the measurement has been exactly  $!$ .

Let us note that  $p = \text{Tr}_F \rho$  and  $\bar{p} = \int_F \rho(d!) = I(F)[\rho]$  are the marginals of the state  $\rho$  on the algebras  $L^1(F; Q)$  and  $L(H)$ , respectively. Then,  $S(\rho | p, \bar{p})$  is a first example of a mutual entropy. From Eqs. (3) and (1) we get

$$S(\rho | p, \bar{p}) = S_q(\rho) - \int_F \rho(d!) \log \bar{p}(d!) = S_q(\bar{p}) - \int_F \rho(d!) \log \bar{p}(d!); \quad (9)$$

Quantities like this one are used in quantum information transmission and are known as Holevo capacities or  $\rho$ -quantities [12,14]; Eq. (9) gives the  $\rho$ -quantity of the ensemble of states  $\rho$ ;

## 2 Continual measurements

Quantum continual measurement theory can be formulated in different equivalent ways. To construct our entropic measures of efficiency, we need two approaches to continual measurements: the one based on positive operator valued measures, instruments, quantum channels [1,5,15] and the one based on classical stochastic differential equations (SDE's), known also as quantum trajectory theory [2,4,16].

The SDE approach to continual measurements is based on a couple of stochastic equations, a linear one for random trace-class operators and a non-linear one for random statistical operators. The two equations are linked by a change of normalization and a change of probability measure. Both equations have a Hilbert space formulation, particularly suited for numerical computations. We shall use a simplified version of SDE's for continual measurements as presented in [2].

### 2.1 The linear equation

Let  $H(t); L_1(t); R_j(t); V_k^x(t); J_k(t)$  be bounded operators on  $H$ ; their time dependence is taken to be continuous from the left and with limits from the right in the strong topology. The indices  $k, l, j$  take a finite number of values; the index  $r$  can take infinitely many values, but in this case the series  $\sum_r V_k^x(t) V_k^x(t)$  is

strongly convergent. Let the operator  $H(t)$  be self-adjoint,  $H(t) = H(t)^*$ , and let us define  $(\otimes \otimes T(H))$

$$J_k(t)[\cdot] = \sum_r V_k^r(t) V_k^r(t) \cdot; \quad J_k(t) = J_k(t) \mathbb{1} = \sum_r V_k^r(t) V_k^r(t); \quad (10)$$

$$L(t) = L_0(t) + L_1(t) + L_2(t); \quad (11)$$

$$L_0(t)[\cdot] = i[H(t); \cdot] + \sum_1 L_1(t) L_1(t) - \frac{1}{2} f L_1(t) L_1(t); g; \quad (12)$$

$$L_1(t)[\cdot] = \sum_j R_j(t) R_j(t) - \frac{1}{2} f R_j(t) R_j(t); g; \quad (13)$$

$$L_2(t)[\cdot] = \sum_k J_k(t)[\cdot] - \frac{1}{2} f J_k(t); g; \quad (14)$$

By  $[\cdot; \cdot]$  we denote the commutator and by  $f; g$  the anticommutator.

Then, we introduce a probability space  $(\cdot; F; Q)$  where the Poisson processes  $N_k(t)$ , of intensity  $\gamma_k$ , and the standard (continuous) Wiener processes  $W_j(t)$  are defined. All the processes are assumed to be independent from the other ones. We introduce also the two-times natural filtration of such processes:

$$F_t^s = f W_j(u) \quad W_j(s); N_k(v) \quad N_k(s); u; v \in [s; t]; j, k = 1; \dots; m; \quad (15)$$

Having all these ingredients, we can introduce the linear equation of continuous measurement theory, for the a trace-class valued process  $\rho_t$ :

$$d\rho_t = L(t)[\rho_t] dt + \sum_j R_j(t) \rho_t + \rho_t R_j(t) dW_j(t) + \sum_k \frac{1}{k} J_k(t)[\rho_t] \rho_t (dN_k(t) - \gamma_k dt); \quad (16)$$

The initial condition is taken to be a non-random statistical operator:  $\rho_0 \in \mathcal{S}(H)$ .

The notation  $\rho_{t-}$  means that, in case there is a jump in the noise at time  $t$ , the value just before the jump  $\rho_{t-}$  of  $\rho_t$  has to be taken. More precisely, if the augmented natural filtration of the noises is considered, the solution can be taken to be continuous from the right and with limits from the left and  $\rho_{t-}$  is just the limit from the left. We prefer not to add the null sets to the natural filtration and by  $\rho_{t-}$  we mean some  $F_t^0$ -adapted version of the solution.

Properties of the solution. Let us consider now, for  $0 \leq s \leq t$ , the von Neumann algebra  $L^1(\cdot; F_t^s; Q; L(H))' \subset L^1(\cdot; F_t^s; Q) \subset L(H)$  (cf. Section 1.1.1) and let us give a name to the set of normal states on this algebra:

$$\mathcal{S}_t^s = \{ \rho \in L^1(\cdot; F_t^s; Q; L(H)) : \rho \geq 0; \text{Tr} \rho = 1; \text{Tr} \rho(d!)gQ(d!) = 1 \}; \quad (17)$$

First of all, it is possible to prove that  $\rho_t \in \mathcal{S}_t^0$ ; we can say that the solution at time  $t$  of Eq. (16) is a kind of quantum/classical state.

The marginals of  $\rho_t$  are (cf. Section 1.2.4):

{ The probability density  $p_t \equiv \text{Tr} f_t g$ . The probability measure  $p_t(\cdot)Q(d\cdot)$  will be the physical probability.

{ The a priori state at time  $t \equiv E_Q[\cdot] \otimes S(H)$ . This is the state to be attributed at time  $t$  to the system when no selection is done and the result of the measurement has not been taken into account.

Moreover, we define the random a posteriori state at time  $t \equiv \frac{1}{p_t} \cdot$ .

This is the state to be attributed at time  $t$  to the system known the result of the measurement up to  $t$ .

Note that  $p_0 = 1, \rho_0 = \rho = \rho, \tau = t = t_+$ .

## 2.2 Physical probabilities

A very important property of Eq. (16) is that  $p_t$  is a mean one  $Q$ -martingale, which implies that

$$P_t(d\cdot) \equiv p_t(\cdot)Q(d\cdot)_{F_t^0} \quad (18)$$

is a consistent family of probabilities, i.e., if  $0 \leq t < T, P_T(F) = P_t(F), \mathcal{F}_T \supset \mathcal{F}_t^0$ . These are taken as physical probabilities.

From Eq. (16) we have that  $p_t$  satisfies the Doléans equation

$$dp_t = p_t \sum_j m_j(t) dW_j(t) + \sum_k \frac{k(t)}{k} (1 - dN_k(t)) k dt; \quad (19)$$

where

$$m_j(t) = \text{Tr} (R_j(t) + R_j(t)) \rho_t; \quad k(t) = \text{Tr} J_k(t) \rho_t; \quad (20)$$

The solution of this equation, with  $p_0 = 1$ , is

$$p_t = \exp \left\{ \sum_j \int_0^t m_j(s) dW_j(s) - \frac{1}{2} \sum_j \int_0^t m_j(s)^2 ds \right. \\ \left. + \sum_k \int_0^t \ln \frac{k(s)}{k} dN_k(s) + \sum_k \int_0^t (k - k(s)) ds \right\}; \quad (21)$$

Remark 1. 1. The output of the continual measurement is the set of processes  $W_j(t), N_k(t), 0 \leq t \leq T$ , under the physical probability  $P$ ;  $T$  is a completely arbitrary large time. By the consistency of the probabilities (18),  $P_T$  can be substituted by  $P_t$  in any expectation involving  $F_t^0$ -measurable random variables (for  $t < T$ ).

2. By Girsanov theorem and its generalizations for situations with jumps, we have that, under the physical probability, the processes

$$\tilde{W}_j(t) = W_j(t) - \int_0^t m_j(s) ds \quad (22)$$

are independent, standard Wiener processes and  $N_k(t)$  is a counting process of stochastic intensity  $k(t)dt$ .

3. Expressions for the moments of the outputs can be given; in particular we have the mean values

$$E_{P_t} [W_j(t)] = \int_0^t n_j(s) ds; \quad E_{P_t} [N_k(t)] = \int_0^t k(s) ds; \quad (23)$$

where

$$n_j(t) = \text{Tr} f(R_j(t) + R_j(t)) \rho_t = E_{P_t} [m_j(t)]; \quad (24a)$$

$$k(t) = \text{Tr} fJ_k(t) \rho_t = E_{P_t} [k(t)]; \quad (24b)$$

## 2.3 The non-linear SDE

Under the physical law  $P_T$ , the a posteriori states  $\rho_t$  satisfy the non-linear SDE

$$d\rho_t = L(t)[\rho_t]dt + \sum_j R_j(t) \rho_t + \rho_t R_j(t) - m_j(t) \rho_t - dW_j(t) \\ + \sum_k \frac{1}{k(t)} J_k(t) [\rho_t] \rho_t - (dN_k(t) - k(t)dt); \quad (25)$$

Let us stress that for the a priori states we have

$$\rho_t = E_Q[\rho_t] = E_{P_t}[\rho_t] \quad (26)$$

and that they satisfy the master equation

$$\frac{d}{dt} \rho_t = L(t)[\rho_t]; \quad (27)$$

## 2.4 The fundamental matrix and the instruments

To apply the notions of Section 1 to continual measurements, we need to see how such a theory is connected to instruments and channels [25]. This is done by introducing the fundamental matrix  $\rho_t^s$  of (16). This operator is defined by stipulating that  $\rho_t^s[j_i]u_j$  satisfies (16) with initial condition  $\rho_0^s[j_i]u_j = j_i]u_j$  where  $f_{j_i} = 1; \dots$  is a c.o.n.s. in  $H$ . It turns out that  $\rho_t^s$  is a channel from  $T(H)$  into  $L^1; F_t^s; Q; T(H)$ , or, by trivial ampliation, from  $L^1; F_s^r; Q; T(H)$  into  $L^1; F_t^r; Q; T(H)$ ,  $0 \leq r \leq s \leq t$ . Then, we have

$$\rho_t^s[\rho_s] = \rho_t; \quad \rho_t^s = \rho_t^u \rho_u^s; \quad 0 \leq s \leq u \leq t; \quad (28)$$

The instrument associated to this channel is

$$I_t^s(F)[\rho] = E_Q[\rho F \rho_t^s[\rho]] \quad \rho_t^s(!)[\rho](d!) = 8F \cdot 2 F_t^s; \quad (29)$$

The time evolution of the quantum states is the one generated by  $L(t)$  and we have

$$U(t;s)[\rho] = I_t^s(\rho)[\rho] = E_Q[\rho_t^s[\rho]]; \quad (30)$$

$$U(t;s)[\rho_s] = \rho_t; \quad U(t;s) = U(t;u) U(u;s); \quad 0 \leq s \leq u \leq t; \quad (31)$$

According to the definitions of Section 1.2.4, the random statistical operator  $\rho_t$  is the a posteriori state for the instrument  $I_t^0$  and the pre-measurement state  $\rho_0$ .

Another important property is

$$E_Q [\tau F_t^s] = \tau [s] 2 S_t^s : \quad (32)$$

Indeed, by the first of (28) and the fact that  $\tau$  is  $F_t^s$ -measurable, we have  $E_Q [\tau F_t^s] = \tau E_Q [s F_t^s]$ . By the fact that all the noises have independent increments, we have that  $s$  is independent from  $F_t^s$  and  $E_Q [s F_t^s] = E_Q [s] = s$ . This gives Eq. (32).

### 3 Mutual entropies and information gains

#### 3.1 The information embedded in the a posteriori states

The quantity  $\tau$  is a state on  $L^1(\cdot; F_t^0; Q; L(H)) = L^1(\cdot; F_t^0; Q) \otimes L(H)$  and its marginals on  $L^1(\cdot; F_t^0; Q)$  and  $L(H)$  are  $p_t$  and  $\tau$ , respectively. The mutual entropy  $S(\tau | p_t)$  is the "information" contained in the joint state with respect to the product of these marginals; more explicitly we have (compare with (9))

$$S(\tau | p_t) = - \int \tau(d!) \text{Tr} \tau(!) \ln \tau(!) \ln \tau$$

and we can write

$$S(\tau | p_t) = E_{p_t} [S_q(\tau | k_t)] = S_q(\tau) - E_{p_t} [S_q(\tau)]: \quad (33)$$

This mutual entropy is a sort of quantum information embedded by the measurement in the a posteriori states. When the measurement is not informative, we have  $\tau(!) = \tau$  and  $S(\tau | p_t) = 0$ . It is zero also if for any reason it happens that  $\tau$  is a pure state. For instance, if  $U(t; 0)$  has a unique equilibrium state which is pure, then  $\lim_{t \rightarrow +\infty} S(\tau | p_t) = 0$  even if the measurement is "good".

Let us note that from Eq. (33) we have the bound

$$S(\tau | p_t) \leq S_q(\tau): \quad (34)$$

When the von Neumann entropy of the a priori state is not zero, an instantaneous index of "goodness" of the measurement could be  $S(\tau | p_t) - S_q(\tau)$ , while a "cumulative" index could be  $\int_0^T \frac{S(\tau | p_t) - S_q(\tau)}{S_q(\tau)} dt$ .

#### 3.2 A classical continual information gain

##### 3.2.1 Product densities

Let us consider any times in the time interval  $(0; t)$  and let us decompose the von Neumann algebra  $L^1(\cdot; F_t^0; Q)$  as  $L^1(\cdot; F_t^0; Q) = L^1(\cdot; F_s^0; Q) \otimes L^1(\cdot; F_t^s; Q)$ . Now, the density  $p_t$  can be seen as a state on  $L^1(\cdot; F_t^0; Q)$  and we can consider its marginals  $p_s^0$  and  $p_t^s$  on the two factors  $L^1(\cdot; F_s^0; Q)$  and  $L^1(\cdot; F_t^s; Q)$ , respectively. These marginals are given by

$$p_s^0 = E_Q [p_t F_s^0]; \quad p_t^s = E_Q [p_t F_t^s]: \quad (35)$$

By using the fact that  $f_{p_t}; t \geq 0$  is a martingale and by taking the trace of Eq. (32), we get

$$p_s^0 = p_s; \quad p_t^s = \text{Tr} f_t^s [s] g: \quad (36)$$

By comparing the last equality with  $p_t = \text{Trf}_t g = \text{Trf}_t^0 [0]g$ , we see that  $p_t^s$  is similar to  $p_t$ , but with  $s$  as initial time, instead of 0, and with  $s$  as initial state, instead of  $0$ . By this remark and Eq. (21), we get

$$p_t^s = \exp \left\{ \sum_j \int_s^{Z_t} m_j(u;s) dW_j(u) - \frac{1}{2} \sum_j \int_s^{Z_t} m_j(u;s)^2 du \right. \\ \left. + \sum_k \int_s^{Z_t} \ln \frac{k(u;s)}{k} dN_k(u) + \sum_k \int_s^{Z_t} (k - k(u;s)) du \right\}; \quad (37)$$

where

$$m_j(t;s) = \text{Tr} (R_j(t) + R_j(t)) \frac{s}{t}; \quad k_k(t;s) = \text{Tr} J_k(t) \frac{s}{t}; \quad (38)$$

$$\frac{s}{t} = \frac{1}{p_t^s} \frac{s}{t} [s]: \quad (39)$$

The random state  $\frac{s}{t}$  is the a posteriori state for the instrument  $I_t^s$  and the pre-measurement state  $s$ ; it satisfy the non-linear SDE (25).

Then, we can consider the mutual entropy  $S_c(p_t k p_s^0 p_t^s)$ . But the significance of this quantity is dubious, because the time  $s$  is completely arbitrary and, moreover, we could divide the time interval in more pieces. For instance, we can take the decomposition  $L^1(\cdot; F_t^0; Q) = L^1(\cdot; F_r^0; Q) \cdot L^1(\cdot; F_s^r; Q) \cdot L^1(\cdot; F_t^s; Q)$  and we recognize that  $p_r^0 p_s^r p_t^s$  is the product of the marginals of  $p_t$  related to this decomposition. Taking a finer generic partition of  $(0;t)$  with  $t_0 = 0$  and  $t_n = t$ , we recognize that  $\prod_{j=1}^n p_{t_{j-1}}^{t_j}$  is again a product of marginals of  $p_t$ . To eliminate arbitrariness, let us consider finer and finer partitions and let us go to a continuous product of marginals.

Let us note that we have

$$\lim_{s \rightarrow t} m_j(t;s) = n_j(t); \quad \lim_{s \rightarrow t} k_k(t;s) = k_k(t); \quad \text{a.s.}$$

Then, for an infinitesimal interval we get

$$p_{s+ds}^s = \exp \left\{ \sum_j \int_s^{Z_t} n_j(s) dW_j(s) - \frac{1}{2} \sum_j \int_s^{Z_t} n_j(s)^2 ds \right. \\ \left. + \sum_k \int_s^{Z_t} \ln \frac{k(s)}{k} dN_k(s) + \sum_k \int_s^{Z_t} (k - k(s)) ds \right\} \quad (40)$$

and, so, the following density  $q_t$  is the continuous product of marginals of  $p_t$ :

$$q_t = \exp \left\{ \sum_j \int_0^{Z_t} n_j(s) dW_j(s) - \frac{1}{2} \sum_j \int_0^{Z_t} n_j(s)^2 ds \right. \\ \left. + \sum_k \int_0^{Z_t} \ln \frac{k(s)}{k} dN_k(s) + \sum_k \int_0^{Z_t} (k - k(s)) ds \right\}; \quad (41)$$

Notice that  $n_j(t)$  and  $k_k(t)$  are deterministic functions. Under the probability  $q_t(!)Q(d!)$ , the processes  $W_j(t) - \int_0^t n_j(s) ds$  are independent, standard Wiener processes and  $N_k(t)$  is a Poisson process of time dependent intensity  $k_k(t)$ .

Under  $q_T (!) Q (d!)$ , the processes  $W_j, N_k$  have independent increments as under  $Q$  (so they can be interpreted as noises), but the means have been changed and made equal to the means they have under  $P_T$ .

The fact that it is possible to consider a "continuous product of marginals" is not so unexpected; indeed, the theory of continuous measurements is connected to infinite divisibility [15].

We have already seen that the marginals of  $p_t$  with respect to the decomposition of the time interval  $(0;t)$  into  $(0;s)$  and  $(s;t)$  are  $p_s^0 = p_s$  and  $p_t^s$  given by Eq. (37). The analogous marginals for  $q_t$  are  $q_s^0 = q_s$  and

$$q_t^s = \exp \left\{ \sum_j \int_t^u n_j(s) dW_j(s) - \frac{1}{2} \sum_j \int_t^u n_j(s)^2 ds + \sum_k \int_t^u \ln \frac{k(s)}{k} dN_k(s) + \sum_k \int_t^u (k - k(s)) ds \right\} = \frac{q_t}{q_s} : \quad (42)$$

### 3.2.2 The classical mutual entropy $S_c(p_t k q_t)$

The density  $q_t$  is no more dependent on some arbitrary choice of intermediate times and the measure  $q_T (!) Q (d!)$  has a distinguished role and can be considered as a reference measure. So, we can introduce the relative entropy

$$S_c(p_t k q_t) = E_{P_t} \ln \frac{p_t}{q_t} :$$

Being  $q_t$  a product of marginals of  $p_t$ , this quantity is a mutual entropy and, being  $q_t$  the nest product of marginals, we can interpret  $S_c(p_t k q_t)$  as a measure of the classical information on the measured system extracted in the time interval  $(0;t)$ . Other reasons can be given to reinforce this interpretation.

By Eqs. (21), (37), (41), (42) we have  $p_t^0 = p_t$ ,  $q_t^0 = q_t$ ,  $q_t = q_t^t$ . By Proposition 1 or by direct computation, we get

$$S_c(p_t k q_t) - S_c(p_s k q_s) = S_c(p_t k p_s^s q_t^s); \quad 0 \leq s \leq t : \quad (43)$$

Firstly, by the positivity of relative entropies, this equation says that

$$0 \leq S_c(p_s k q_s) \leq S_c(p_t k q_t); \quad (44)$$

i.e. that  $S_c(p_t k q_t)$  is non negative and not decreasing in time, as should be for a measure of an information gain in time. Moreover, the increment of information in the time interval  $(s;t)$  can be written as

$$S_c(p_t k p_s^s q_t^s) = E_{Q - p_s} E_Q \frac{p_t}{p_s} \ln \frac{p_t - p_s}{q_t - q_s} F_s^0 : \quad (45)$$

This expression can be interpreted as a conditional relative entropy ([17] pp. 22{23}). The quantity  $E_Q \frac{p_t}{p_s} \ln \frac{p_t - p_s}{q_t - q_s} F_s^0$  has the same structure as  $S_c(p_t k q_t)$ , but it refers to the interval  $(s;t)$  and it is constructed with the conditional densities. We can say that Eq. (43) expresses in a consistent way a kind of "additivity property" of our measure of information.

Having the explicit exponential forms of the densities  $p_t$  and  $q_t$ , we can compute the explicit expression of the information gain.

Proposition 4. The explicit expression of the classical mutual entropy  $S_c(p_t k_q)$  is

$$S_c(p_t k_q) = \frac{1}{2} \sum_j \int_0^{Z_t} \text{Var}_{P_t} [n_j(s)] ds + \sum_k \int_0^{Z_t} E_{P_t} [k(s) \ln \frac{k(s)}{k(s)}] ds \quad (46)$$

Proof. By Eqs. (21) and (41) we get

$$\begin{aligned} \ln \frac{p_t}{q_t} &= \sum_j \int_0^{Z_t} m_j(s) - n_j(s) dW_j(s) - \frac{1}{2} \sum_j \int_0^{Z_t} m_j(s)^2 - n_j(s)^2 ds \\ &+ \sum_k \int_0^{Z_t} \ln \frac{k(s)}{k(s)} dN_k(s) - \sum_k \int_0^{Z_t} k \ln \frac{k(s)}{k(s)} ds + \sum_k \int_0^{Z_t} k(s) + k(s) ds \\ &= \sum_j \int_0^{Z_t} m_j(s) - n_j(s) dW_j(s) - \sum_j \int_0^{Z_t} m_j(s) ds + \frac{1}{2} \sum_j \int_0^{Z_t} m_j(s) - n_j(s)^2 ds \\ &\quad + \sum_k \int_0^{Z_t} \ln \frac{k(s)}{k(s)} dN_k(s) - \sum_k \int_0^{Z_t} k(s) ds \\ &\quad + \sum_k \int_0^{Z_t} k(s) - \frac{k(s)}{k(s)} \ln \frac{k(s)}{k(s)} - 1 ds : \end{aligned}$$

By point 2 in Remark 1, the first term in the  $j$  sum and the first term in the  $k$  sum have zero mean under  $P_T$  (or under  $P_t$ , by consistency). Therefore, Eq. (46) follows by taking the  $P_t$ -mean of  $\ln p_t = q_t$  and by taking into account Eqs. (24).  $\square$

Remark 2. 1. By (24b) and Jensen inequality applied to the convex function  $x \ln x$ , we have that both integrands in formula (46) are non-negative and, so, we have

$$\frac{d}{dt} S_c(p_t k_q) = \frac{1}{2} \sum_j \text{Var}_{P_t} [n_j(t)] + \sum_k E_{P_t} [k(t) \ln \frac{k(t)}{k(t)}] \geq 0 : \quad (47)$$

The positivity of this time derivative follows also from Eq. (44).

2. By the properties of relative entropy  $E_{P_T} [S_q(p_t k_t)] = 0$  is equivalent to  $p_t = q_t, P_T$ -a.s. By Eqs. (24), (47), this last relation implies the vanishing of the quantity (47). So, we have

$$E_{P_T} [S_q(p_t k_t)] = 0 \implies \frac{d}{dt} S_c(p_t k_q) = 0 : \quad (48)$$

3. From Eqs. (20), (24), (47) we see that

$$\begin{aligned} \text{if } R_j(t) + R_j(t) &\neq 1, \text{ then } \text{Var}_{P_t} [n_j(t)] = 0, \\ \text{if } J(t) &\neq 1, \text{ then } \ln \frac{k(t)}{k(t)} = 0. \end{aligned}$$

This says that when both conditions hold for all  $j$  and  $k$ , no information is extracted from the system, whatever the initial state is.

### 3.3 A quantum /classical mutual entropy

The two mutual entropies introduced in Sections 3.1 and 3.2.2 can be obtained from a unique mutual entropy

$$S(\rho_t k_{\mathbb{F}} \rho_t) = \sum_{d \in \mathcal{D}} \text{Tr}(\rho_t(!)) \ln \rho_t(!) - \ln q(!) \rho_t : \quad (49)$$

Indeed, by Proposition 1 or by direct computation, we get

$$S(\rho_t k_{\mathbb{F}} \rho_t) = S(\rho_t k_{\mathbb{P}} \rho_t) + S_c(\rho_t k_{\mathbb{F}}) = E_{\mathbb{P}_t}[S_q(\rho_t k_{\mathbb{F}})] + S_c(\rho_t k_{\mathbb{F}}) : \quad (50)$$

## 4 An upper bound on the increments of $S_c(\rho_t k_{\mathbb{F}})$

### 4.1 The main bound

By Proposition 1 and Eqs. (21), (37), (41), (42), the increment of information in the time interval  $(t; u)$  can be expressed as

$$S_c(\rho_u k_{\mathbb{F}}) - S_c(\rho_t k_{\mathbb{F}}) = S_c(\rho_u k_{\mathbb{P}} \rho_u^t) + S_c(\rho_u^t k_{\mathbb{F}}^t) : \quad (51)$$

Lemma 5. For  $0 \leq t \leq u$ , we have the bound

$$0 \leq S_c(\rho_u k_{\mathbb{P}} \rho_u^t) - E_{\mathbb{P}_u}[S_q(\rho_t k_{\mathbb{F}})] - S_{q-u} k_{\mathbb{F}}^t : \quad (52)$$

Proof. Consider the mutual entropy  $S(\rho_t k_{\mathbb{P}} \rho_t)$  introduced in Section 3.1 and apply to both states the channel  $\rho_u^t$ . By Theorem 2 and the definition (39) we get the inequality

$$\begin{aligned} E_{\mathbb{P}_t}[S_q(\rho_t k_{\mathbb{F}})] &= S(\rho_t k_{\mathbb{P}} \rho_t) - S_{\mathbb{F}}^t[\rho_t] k_{\mathbb{F}}^t[\rho_t] = S_{\mathbb{F}}^t k_{\mathbb{P}} \rho_u^t \\ &= S_{\mathbb{P}_u} k_{\mathbb{P}} \rho_u^t \rho_u^t = E_{\mathbb{P}_u} \text{Tr} \rho_u \ln \rho_u + \ln \rho_u - \ln \rho_t \rho_u^t - \ln \rho_u^t \\ &= S_c(\rho_u k_{\mathbb{P}} \rho_u^t) + E_{\mathbb{P}_u}[S_{q-u} k_{\mathbb{F}}^t] ; \end{aligned}$$

and this gives (52).  $\square$

Apart from the different notations, Eq. (52) is the bound (29) in Ref. [5]. From Eqs. (40) and (42) we get immediately

$$\lim_{u \rightarrow t} \frac{S_c(\rho_u^t k_{\mathbb{F}}^t)}{u - t} = 0 : \quad (53)$$

Then, the second summand in the expression (51) of the increment of information becomes negligible with respect to the first when  $u \rightarrow t$ . Therefore, from Lemma 5 we have immediately the following theorem.

Theorem 6 (The bound on the derivative of  $S_c(\rho_t k_{\mathbb{F}})$ ). The following bound holds:

$$\begin{aligned} 0 \leq \frac{d}{dt} S_c(\rho_t k_{\mathbb{F}}) &= \frac{d}{dt} E_{\mathbb{P}_t}[S_q(\rho_t k_{\mathbb{F}})]_{u=t^+} \\ &= \frac{d}{dt} E_{\mathbb{P}_t}[S_q(\rho_t)]_{u=t^+} - \frac{d}{dt} E_{\mathbb{P}_t}[S_q(\rho_t^t)]_{u=t^+} : \quad (54) \end{aligned}$$

Remark 3. We already saw in Remark 2 that  $E_{P_T} [S_q(t_k t)] = 0$  is equivalent to  $t = t, P_T - a.s.$ ; but this implies  $u = \frac{t}{u}, P_T - a.s.$ , because in this case these two quantities, which satisfy the same equation, have the same initial condition at time  $t$ . Therefore we have  $E_{P_T} [S_q(u k \frac{t}{u})] = 0, \forall u \geq t$ , and

$$E_{P_T} [S_q(t_k t)] = 0 \quad \left( \frac{d}{du} E_{P_T} [S_q(u k \frac{t}{u})] \right)_{u=t^+} = 0: \quad (55)$$

## 4.2 Explicit computation of the bound

All the derivatives can be elaborated and from Eq. (54) we get the following explicit form of the difference between the bound and the time derivative in which we are interested in.

Proposition 7. By computation of all the terms appearing in Eq. (54) we get

$$\begin{aligned} & 0 - \frac{d}{dt} E_{P_T} [S_q(t)] - \frac{d}{du} E_{P_T} [S_q(\frac{t}{u})]_{u=t^+} - \frac{d}{dt} S_c(p_t k q_t) \\ &= E_{P_T} \left[ \text{Tr} J_k(t) \left( \ln \frac{t}{t} - \ln \frac{t}{t} \right) - J_k(t) [t] (\ln J_k(t) [t] - \ln J_k(t) [t]) \right] \\ &+ \sum_k E_{P_T} \left[ \text{Tr} R_j(t) \left( \ln \frac{t}{t} - \ln \frac{t}{t} \right) - R_j(t) \left( \ln \frac{t}{t} - \ln \frac{t}{t} \right) \right] \\ &+ \sum_j E_{P_T} \left[ \text{Tr} L_1(t) \left( \ln \frac{t}{t} - \ln \frac{t}{t} \right) - L_1(t) \left( \ln \frac{t}{t} - \ln \frac{t}{t} \right) \right] \\ &+ \frac{1}{2} \sum_j E_{P_T} \int_0^{Z+1} du \text{Tr} R_j(t) \frac{t}{u+t} R_j(t) \frac{t}{u+t} \\ &\quad R_j(t) \frac{t}{u+t} R_j(t) \frac{t}{u+t} \\ &+ \frac{t}{u+t} R_j(t) \frac{t}{u+t} R_j(t) - \frac{t}{u+t} R_j(t) \frac{t}{u+t} R_j(t) \\ &+ \frac{2}{u+t} R_j(t) \frac{t^2}{u+t} R_j(t) - \frac{2}{u+t} R_j(t) \frac{t^2}{u+t} R_j(t) : \quad (56) \end{aligned}$$

Proof. Let us start with the term  $\frac{d}{du} E_{P_T} [S_q(\frac{t}{u})]_{u=t^+}$ . By recalling that  $\frac{t}{u}$  satisfies in  $u$  the non-linear SDE with initial condition  $\frac{t}{t}$  at  $u = t$  and that  $\frac{t}{t} + L(t) [t] dt = \frac{t}{t+dt}$ , we get

$$\frac{t}{t+dt} - \frac{t}{t} dt = \sum_j A_j(t) dW_j(t) + \sum_k (k(t) - t) (dN_k(t) - k(t) dt);$$

where

$$A_j(t) := R_j(t) \frac{t}{t} + \frac{t}{t} R_j(t) - n_j(t) \frac{t}{t}; \quad k(t) := \frac{1}{k(t)} J_k(t) [t];$$

$$dW_j(t) := dW_j(t) - n_j(t) dt;$$

By setting also

$$B(t) := \frac{1}{2} \sum_k f J_k(t) - k(t); \quad t g + L_0(t) [t] + L_1(t) [t];$$

we can write

$$1_{t \leq t+dt} = 1 - \sum_k \lambda_k(t) dt + \sum_k \lambda_k(t) dt + B(t) dt :$$

Moreover, by the properties of the increments of the counting processes, we have

$$dN_k(t) = \lambda_k(t) dt + dW_k(t) :$$

$$\begin{aligned} 1_{t \leq t+dt} &= 1 - \sum_k \lambda_k(t) dt + \sum_k \lambda_k(t) dt + B(t) dt + \sum_j A_j(t) dW_j(t) \\ &= 1 - \sum_k \lambda_k(t) dt + B(t) dt + \sum_j A_j(t) dW_j(t) : \end{aligned}$$

By putting these things all together and by using the rules of stochastic calculus, we get

$$\begin{aligned} \ln \frac{t}{t+dt} &= \ln t - \ln(t+dt) = - \sum_k \lambda_k(t) dt + B(t) dt + \sum_j A_j(t) dW_j(t) \\ &= - \sum_k \lambda_k(t) dt + B(t) dt + \sum_j A_j(t) dW_j(t) \\ &= - \sum_k \lambda_k(t) dt + B(t) dt + \sum_j A_j(t) dW_j(t) : \end{aligned}$$

It exists a nearly obvious and very useful integral representation of the logarithm of an operator ([6] p. 51):

$$\ln A = \int_0^{Z+1} \frac{1}{1+t} \frac{1}{t+A} dt :$$

By iterating this formula we get also

$$\begin{aligned} \ln(A+B) - \ln A &= \int_0^{Z+1} \frac{1}{t+A} B \frac{1}{t+A+B} dt \\ &= \int_0^{Z+1} \frac{1}{t+A} B \frac{1}{t+A} dt - \int_0^{Z+1} \frac{1}{t+A+B} dt : \end{aligned}$$

These two formulae and stochastic calculus rules allow to write

$$\begin{aligned} E_{P_T} \text{Tr} \int_0^t \ln \frac{t}{t+dt} &= \text{Tr} \int_0^t \ln \frac{t}{t+dt} = \sum_k \int_0^t S_k(t) S_k(t) dt \\ &= \sum_k \int_0^t S_k(t) S_k(t) dt \\ &= \sum_k \int_0^t S_k(t) S_k(t) dt \\ &= \sum_k \int_0^t S_k(t) S_k(t) dt \\ &= \sum_k \int_0^t S_k(t) S_k(t) dt : \end{aligned}$$

By computing the integral we get

$$\begin{aligned}
\text{Tr } B(t) \ln_t + \int_0^{Z+1} \frac{t}{(u+t)^2} du &= \text{Tr} fB(t) (\ln_t + \mathbb{1})g \\
&= \text{Tr} fB(t) \ln_t g = \sum_k \text{Tr} f[J_k(t) - J_k(t)]_t \ln_t g \\
&\quad + \sum_j \text{Tr} f[R_j(t) - R_j(t) - R_j(t) - R_j(t)]_t \ln_t g \\
&\quad + \sum_l \text{Tr} f[L_1(t) - L_1(t) - L_1(t) - L_1(t)]_t \ln_t g
\end{aligned}$$

and by using the integration by parts with  $\frac{1}{(u+t)^2} = \frac{d}{du} \frac{1}{u+t}$  we have also

$$\begin{aligned}
\sum_j \int_0^{Z+1} du \text{Tr} \frac{1}{u+t} A_j(t) \frac{1}{u+t} A_j(t) &= \sum_j \int_0^{Z+1} du \text{Tr} A_j(t) \frac{1}{(u+t)^2} A_j(t) \frac{u}{u+t} \\
&= \sum_j \int_0^{Z+1} du \text{Tr} A_j(t) \frac{t}{(u+t)^2} A_j(t) \frac{1}{u+t} \\
&= \frac{1}{2} \sum_j \int_0^{Z+1} du \text{Tr} \frac{1}{u+t} A_j(t) \frac{1}{u+t} A_j(t) :
\end{aligned}$$

From the previous formulae we have the final expression

$$\begin{aligned}
\frac{d}{du} E_{P_T} [S_q(\frac{t}{u})]_{u=t^+} &= \sum_k \text{Tr} J_k(t)_t \ln \frac{J_k(t)_t}{J_k(t)} - J_k(t)_t \ln_t \\
&\quad + \sum_j \text{Tr} R_j(t)_t R_j(t) ; \ln_t + \sum_l \text{Tr} L_1(t)_t L_1(t) ; \ln_t \\
&\quad + \frac{1}{2} \sum_j \int_0^{Z+1} du \text{Tr} R_j(t) \frac{t}{u+t} R_j(t) \frac{t}{u+t} + \frac{t}{u+t} R_j(t) \frac{t}{u+t} R_j(t) \\
&\quad + \frac{2}{u+t} R_j(t) \frac{t^2}{u+t} R_j(t) - n_j(t)^2 : \quad (57)
\end{aligned}$$

Analogously we get

$$\begin{aligned}
\frac{d}{dt} E_{P_T} [S_q(\frac{t}{t})] &= \sum_k E_{P_T} \text{Tr} J_k(t)_t \ln \frac{J_k(t)_t}{J_k(t)} - J_k(t)_t \ln_t \\
&\quad + \sum_j E_{P_T} \text{Tr} R_j(t)_t R_j(t) ; \ln_t + \sum_l E_{P_T} \text{Tr} L_1(t)_t L_1(t) ; \ln_t \\
&\quad + \frac{1}{2} \sum_j \int_0^{Z+1} du \text{Tr} R_j(t) \frac{t}{u+t} R_j(t) \frac{t}{u+t} \\
&\quad + \frac{t}{u+t} R_j(t) \frac{t}{u+t} R_j(t) + \frac{2}{u+t} R_j(t) \frac{t^2}{u+t} R_j(t) - m_j(t)^2 : \quad (58)
\end{aligned}$$

By (57), (58), (47) we get the statement of the Proposition.  $\square$

Corollary 8. A sufficient condition to have the equality in the main bound

$$\frac{d}{dt} S_c(p_k q_k) = \frac{d}{dt} E_{P_T} [S_q(t)] - \frac{d}{du} E_{P_T} [S_q(\frac{t}{u})]_{u=t^+} \quad (59)$$

is to have  $P_T$ -a.s. in  $! (T - t)$

$$[V_k^x(t); t(!)] = 0; [R_j(t); t(!)] = 0; [L_1(t); t(!)] = 0; \quad 8r; k; j; l: \quad (60)$$

In the autonomous case, i.e. when  $H; V_k^x; R_j; L_1$  are time independent, we have that the conditions

$$[H; 0] = 0; [V_k^x; 0] = 0; [R_j; 0] = 0; [L_1; 0] = 0; \quad 8r; k; j; l: \quad (61)$$

imply Eqs. (60) and (59)  $8t \geq 0$ .

Proof. By the commutation relations (60) we get

$$\begin{aligned} J_k(t) t (\ln t - \ln t) - J_k(t) [t] (\ln J_k(t) [t] - \ln J_k(t) [t]) \\ = J_k(t) t (\ln t - \ln t - \ln J_k(t) t + \ln J_k(t) t) = 0 \end{aligned}$$

and the first term in Eq. (56) vanishes.

By Eq. (60) also the second and third term in Eq. (56) vanish because they explicitly involve vanishing commutators.

Finally, let us consider one of the summands in (56). We have

$$\begin{aligned} E_{P_T} \int_0^{Z+1} du \operatorname{Tr} R_j(t) \frac{t}{u+t} R_j(t) \frac{t}{u+t} \\ = E_{P_T} \int_0^{Z+1} du \operatorname{Tr} R_j(t)^2 \frac{t^2}{(u+t)^2} \\ = E_{P_T} \operatorname{Tr} R_j(t)^2 t = \operatorname{Tr} R_j(t)^2 t : \end{aligned}$$

Similar formulae hold also for the other summands and the last term vanishes too.

In the autonomous case, when the initial state  $\rho_0 = \rho_0$  commutes with all the operators involved in the evolution equations, we get that Eqs. (60) hold for all  $t$  and the conclusion follows from the first part of the corollary.  $\square$
