Abstract

The problem of finding the large order asymptotics for the eigenfunction perturbation theory in quantum mechanics is studied. The relation between the wave function argument x and the number of perturbation theory order k that allows us to construct the asymptotics by saddle-point technique is found: $x = k^{1/2} = \text{const}; k \rightarrow \infty$. Classical ideal solutions starting from the classical vacuum play an important role in constructing such asymptotics. The correspondence between the trajectory end and the parameter $x = k^{1/2}$ is found. The obtained results can be applied to the calculation of the main values of the observables depending on k in the k -th order of perturbation theory at large k and, probably, to the multiparticle production problem.

It is well-known that the perturbation series in quantum mechanics, as well as in quantum field theory, diverges [1] because of the factorial growth of the coefficients at large orders. High order asymptotics of the coefficients, which is important, for example, for the problem of the divergent series summation, has been discussed in many papers. For the quantities such as the ground state energy in quantum mechanics [2, 3] or Green functions in quantum field theory [4], the asymptotics is determined by the euclidean finite action classical solution satisfying the following boundary conditions: when "euclidean time" tends to ± 1 , the euclidean solution tends to the classical vacuum.

In this paper the role of classical euclidean solutions with other boundary conditions is discussed. It occurs that when the large order asymptotics not for eigenvalue, but for eigenfunction in quantum mechanics is considered, one must treat the classical trajectory starting from the classical vacuum as ± 1 but finishing at some point Q as $Q \rightarrow 0$.

Namely, consider, as usual, the following dependence of the Hamiltonian on the perturbation theory parameter g ,

$$H = -\frac{1}{2} \Delta + \frac{1}{g^2} V(gx); \quad (1)$$

where Δ is the Laplace operator, $x = (x_1; \dots; x_n)$ is a set of coordinates, function V is a potential, which has a local minimum as its argument is equal to zero. Without loss of generality, suppose that $V(Q) = Q^2 + O(Q^3)$ as $Q \rightarrow 0$. The dependence (1) was considered in [2, 3].

Consider the perturbation theory for the ground state eigenfunction. This perturbation theory can be treated in several ways, namely, one can change the variable $gx = Q$ and consider the wave function asymptotic expansion at fixed Q ; this expansion is a tunnel semiclassical expansion because of the dependence (1), the analog of the Planck constant is g^2 . Large order asymptotics of semiclassical expansion can be

also found [5], and the asymptotics of the ground state energy perturbation theory, which was obtained in [2, 3, 6, 7] for various cases can be checked [5].

Nevertheless, consider in this paper the ordinary way of treating the eigenfunction perturbation theory,

$$\psi(x) = \sum_{k=0}^{\infty} g^k \psi_k(x); \quad (2)$$

The purpose is to find the ψ_k asymptotics at large k . In order to do it, let us write ψ_k through the functional integral. Make use of the path integral representation of the ground state wave function,

$$\psi(x) = \int Dq \exp \left\{ -\frac{1}{g^2} S[q] \right\};$$

where the integral is taken over the trajectories $q(\cdot)$ satisfying the boundary conditions, $q(-1) = 0; q(0) = x$; and S is the euclidean action of the theory,

$$S[q] = \int_{-1}^0 dQ \left[\frac{1}{2} \dot{Q}^2 + V(Q) \right]; \quad (3)$$

One can develop the perturbation theory for the ground state wave function with the help of the expansion of the integrand in the path integral representation into a series in g , the k -th order of this expansion can be written as a contour integral, so the k -th order of the wave function is given by

$$\psi_k(x) = \int_{C(q)} Dq \int \frac{dg}{2ig^{k+1}} \exp \left(-\frac{1}{g^2} S[q] \right); \quad (4)$$

the contour $C(q)$ runs around the origin counterclockwise.

Let us transform the integral (4) to a saddle-point form. For this purpose rescale the variables $q(\cdot)$ and g in $\frac{1}{k}$ times:

$$g = \frac{1}{k} g_0; q(\cdot) = \frac{1}{k} q_0(\cdot); \quad (5)$$

This substitution means that the boundary condition for $q, q(0) = x$, must be rescaled in $\frac{1}{k}$ times, too. Thus, the ψ_k asymptotics at large k and fixed x is not of a saddle-

point type, while such asymptotics as

$$k \rightarrow 1; x = \frac{p_-}{k} \rightarrow 0 = \text{const} \quad (6)$$

is obtained from the rescaled integral with the help of saddle-point technique and is given by the following expression,

$$k(0) = \frac{p_-}{k} \quad (k=2) \exp(-kA(0)); \quad (7)$$

where the function A equaling to

$$A(0) = -\frac{1}{2} S \left[\frac{p_-}{k} \right] + \frac{1}{2} \left(\ln \frac{p_-}{2} - 1 \right) \quad (8)$$

is taken in the extremum point, is a trajectory starting from zero as $k \rightarrow 1$ and finishing at the point 0 as $k = 0$. Varying the trajectory $Q(k)$, one can obtain that the function $Q(k) = \frac{p_-}{k}$ satisfies the classical euclidean equation of motion,

$$Q = r V(Q); \quad (9)$$

When one varies the quantity k , the following equation for it can be obtained:

$$2 = \int_0^Q dQ [V(Q) - Q r V(Q)] = 2; \quad (10)$$

where $2 \in (-1; 0]$. We can treat the parameter (10) as a function of the end $Q(0) = Q$ of the classical trajectory $Q(k)$ satisfying eq.(9). So we obtain the following relations connecting the point Q and the parameter 0 in eq.(6),

$$Q = \frac{p_-}{k(Q)} = 0; \quad (11)$$

When one searches for the asymptotic formula for k under conditions (6), one must first find the boundary condition for the classical euclidean solution at $k = 0$ from eq.(11), then find the classical trajectory arriving at this euclidean time moment in point Q and, finally, substitute the classical euclidean action on the trajectory and the parameter 0 to eq.(7). Notice that the function k in eq.(11) can be multivalued.

The correspondence (11) is non-trivial and interesting. Namely, suppose the trajectory $Q(\tau)$ to spend all euclidean time in the vicinity of the point $Q = 0$, so that the coordinates of the trajectory end are small. Then the parameter τ_0 is of order $O(Q^3)$. Therefore, the corresponding value of τ_0 is large. Thus, if one makes an attempt to find the behaviour of the asymptotics at large τ_0 , trajectories closed to the path $Q = 0$ must be taken into account, so one is in need only of knowledge of the first non-vanishing term of the difference $V - Q^2/2$ at small Q . This statement can be illustrated as follows. In each order of the perturbation theory the wave function is expressed as a product of the $3k$ -th order polynomial in x function by the Gaussian exponent. It is the term of order x^{3k} expressed only through the third derivatives $\partial^3 V = \partial Q_i \partial Q_j \partial Q_k$ of the potential V at $Q = 0$ that becomes the main one at large τ_0 .

We have seen that classical euclidean solutions starting at $\tau = -1$ from zero correspond to large order behaviour of τ_k , while the parameter τ_0 in the condition (6) depends on the coordinates of the trajectory end. We can consider all such points in Q -space that the discussed classical trajectory passes through them. According to eq.(11), each such point Q can be associated with the corresponding point in τ_0 -space by shifting of the parameter τ to a constant in order to make the euclidean time moment at which the trajectory passes through the point Q to be equal to zero. Therefore, each trajectory in Q -space is related with the trajectory in τ_0 -space (9.1), $\tau_0(\tau) = Q(\tau) = \int_{\tau_0(0)}^{\tau} Q(\tau) d\tau$: Focus the attention on the distinction between this path and the trajectory $\tau_0(\tau) = Q(\tau) = \int_0^{\tau} Q(0) d\tau$: According to the previous discussion, the trajectory $\tau_0(\tau)$ starts from infinity, while the trajectory $\tau_0(\tau)$ starts from the origin. Another interesting feature of the path $\tau_0(\tau)$ is that the derivative of the function A with respect to τ_0 is written in the form, $A'(\tau_0(\tau)) = \tau_0^{-1}$, where $\tau_0 = Q^{-1}$. The form is analogous to the formula $dS = P dQ$.

If the trajectory in Q -space finishes as $\tau \rightarrow +1$ at zero then the corresponding

curve in ϕ_0 -space finishes in the point $\phi_0 = 0$ as $Q \rightarrow +1$, too, because the integral (10) becomes the classical action at large Q , which is not equal to zero. Thus, when one makes an attempt to find the asymptotics at small ϕ_0 , one must consider the classical trajectory closed to the loop-like euclidean solution (9.1) with the action S_0 . Since the function ϕ_0 is approximately equal to $2S_0$ up to $O(Q^{-3})$, the function A is equal to $\frac{1}{2} \ln S_0 - \frac{Q^2}{4S_0}$ to the same accuracy. The k -th asymptotics as $k \rightarrow \infty$ is, therefore, given by $(k=2)S_0^{k=2} e^{k^2=2}$. Notice that the pre-exponential factor in the k -th asymptotics, which is omitted in this formula, diverges. Namely, it is connected with the determinant of fluctuations near the classical solution. When Q is small and the trajectory is closed to the loop-like solution, we come across the "almost zero mode" of the solution: when we shift the parameter to a large constant, $Q(0)$ is shifted to the small quantity. So the determinant is small. Therefore, we can expect the following form of the k -th asymptotics at fixed x and large k ,

$$\frac{(k=2)}{S_0^{k=2}} (x); \quad (12)$$

where (x) is not square integrable because of its exponential growth at large x , $(x) \sim e^{x^2=2}$.

Since the ground state eigenvalue is defined by the behaviour of the eigenfunction near the point $\phi_0 = 0$, large order asymptotics of perturbation theory for it has the form similar to (12) up to a pre-exponential factor. This formula coincides with the results obtained in [2, 6, 3, 7].

Notice that the presented method can be applied to high order behaviour of perturbation theory not only for the ground state wave function but also for the ground state density matrix equaling to the product $\rho = \psi(x) \psi(y)$ because of the reality of the ground state wave function. The density matrix and the k -th order for it can be presented in a form analogous to (4). We can change the variables like eq.(5) and

and the k -asymptotics as

$$k! \sim 1; x = \frac{P}{k}; y = \frac{P}{k} \quad (13)$$

which is given by

$$k! \sim \frac{P}{k} \exp \left(\sum_{k=2}^{\infty} \frac{1}{k} (S^{(1)} + S^{(2)}) \right) + \frac{1}{2} \ln \frac{1}{2} \quad (14)$$

where $S^{(1)}$ and $S^{(2)}$ are the trajectories satisfying the boundary conditions $S^{(1)}(0) = \frac{P}{2}$; $S^{(2)}(0) = \frac{P}{2}$. We can also obtain that the trajectories $Q_1 = S^{(1)}$ and $Q_2 = S^{(2)}$ are classical, while the parameter $\beta = 2$ is equal to the sum of the integrals (10) corresponding to these two euclidean solutions. Notice that eq.(14) can be also obtained by making use of the k -asymptotics under conditions (6), but the derivation is not so trivial, because one is in need of estimation of the sum $\sum_{n=0}^P k_n(x) k_n(y)$ under conditions (13).

Consider the loop-like trajectory $Q(\beta)$ shown in fig.1. Let $Q_1(\beta) = Q(\beta)$; $Q_2(\beta) = Q(\beta)$; $\beta < 0$: This set of trajectories contributes to the asymptotics (14) at following values of β ; $\beta_1 = \beta_2 = Q(0) = \frac{P}{2S_0}$; while the parameter is equal to $2S_0$, so that the asymptotics (14) at coinciding arguments takes the form $(k=2)S_0^{k=2}$. Thus, we see that for finding the density matrix large order asymptotics at coinciding arguments which is necessary for obtaining the asymptotics of the main values of the operators like $x_{i_1} \dots x_{i_n}$ ("Green functions") one is in need of making use of classical solution $Q(\beta)$, and the corresponding asymptotics has the form analogous to the ground state energy large order behaviour. This result is in agreement with the technique developed in [4].

But the results obtained in the present paper allow us to find the asymptotic behaviour of the k -th order of perturbation theory for the main values of the observables \hat{O} being the operators with the kernels $O(x; y; k)$ depending on k as follows, $O(x; y; k) = f\left(\frac{P}{k}; \frac{P}{k}\right) \exp(kg\left(\frac{P}{k}; \frac{P}{k}\right))$. Namely, these quantities being

the integrals $\int_{\mathbb{R}^n} dx dy \, \phi_k(x; y) \phi_0(x; y; k)$ can be approximately calculated by making use of eq.(14) and applying the Laplace method.

One can also calculate other quantities. Namely, the k -th order of perturbation theory for the wave functions is presented as a product of a polynomial function $\prod_{i_1, \dots, i_n} a_{i_1, \dots, i_n} x_1^{i_1} \dots x_n^{i_n}$ by the Gaussian exponent $e^{-x^2/2}$. It occurs that the obtained result (7) allows us to find the a_{i_1, \dots, i_n} asymptotics as $i_1=k; \dots; i_n=k$ tend to constants, because these coefficients can be written through the contour integrals having the saddle-point form under mentioned conditions.

The investigation of the wave function large order asymptotics gives us a possibility to substitute it to perturbative recursive relations, to check the exponential approximation (7) and to find the pre-exponential factor, as well as the corrections, not only by calculating the determinant of fluctuations in the path integral approach, but also by direct analysis of recursive relations, which allows us to consider the cases of singular quantum corrections [7] to the Hamiltonian and of instanton-anti-instanton pair [6]. For semiclassical expansion such analysis was made in [5]. From the recursive relations research one can also confirm the asymptotics (12) and find the function ϕ_0 in it.

I hope that the suggested method of constructing asymptotics can clarify the problem: what classical solutions contribute to the large orders of perturbation theory and, in particular, find the correspondence between the existence of this contribution and the parity of a number of negative modes around the euclidean solution. The correspondence was found in [7] for the ground state energy and confirmed in [5] for the large orders of semiclassical expansion.

Probably, the suggested method can give rise to a new vision of a multiparticle production problem considered recently in many papers, see, for example, [8, 9, 10, 11]. For considering this problem it is important to know the behaviour of Feynman

diagram with a large number of the external lines and a large number of vertices, i.e. the main values of the observables depending on k in the k -th order of perturbation theory at large k which has been already discussed.
