Version of 17 M ay 1995

#### Abstract

P recise rules are developed in order to form alize the reasoning processes involved in standard non-relativistic quantum $m$ echanics, $w$ ith the help of analogies from classical physics. A classical or quantum description of a $m$ echanical system involves a fram ework, often chosen im plicitly, and a statem ent or assertion about the system which is either true or false within the fram ew ork with which it is associated. Q uantum descriptions are no less \ob jective" than their classical counterparts, but di er from the latter in the follow ing respects: (i) T he fram ew ork em ploys a $H$ ilbert space rather than a classical phase space. (ii) T he rules for constructing m eaningful statem ents require that the associated projectors com $m$ ute $w$ ith each other and, in the case of tim e-dependent quantum histories, that consistency conditions be satis ed. (iii) T here are incom patible fram eworks which cannot be combined, either in constructing descriptions or in $m$ aking logical inferences about them, even though any one of these fram ew orks m ay be used separately for describing a particular physical system.

A new type of \generalized history" is introduced which extends previous proposals by $O m$ nes, and $G$ ell-M ann and $H$ artle, and a corresponding consistency condition which does not involve density $m$ atrices or single out a direction of tim e. A pplications which illustrate the form alism include: m easurem ents of spin, two-slit di raction, and the em ergence of the classical world from a fully quantum description.

## I Introduction

Seventy years after non-relativistic quantum m echanics reached what is essentially its present form, the ongoing controversy over its conceptual foundations and the proper interpretation of w ave functions, $m$ easurem ents, quantum probabilities, and the like show s no sign of abating. Indeed, $m$ odem experim ents involving neutron di raction, ions in traps, and quantum optics seem to cry out for a m ore satisfactory form ulation of basic quantum ideas than was available to Feynm an [i] when he rem arked, in com paring special relativity and quantum

[^0]theory，that while the form er was well understood，\nobody understands quantum m echan－ ics．＂

This lack of understanding $m$ anifests itself in various ways．Take，for exam ple，the well－
 From this itm ight seem reasonable to conclude that allderivations ofB ell＇s inequality contain one orm ore errors，in the sense that either the prem ises or the procedures of logical inference entering the argum ent violate one or $m$ ore principles of standard quantum m echanics．H ad som eone in 1964 attem pted to publish an inequality violating the predictions of special relativity，the experts would have pointed out precisely where the reasoning went astray as soon as the argum ent reached the printed page，if not earlier．But this did not happen in the case of Bells work．Indeed，m uch of the subsequent literature on the sub ject［3］w ould lead one to believe that standard quantum $m$ echanics is either w rong，or illogical，or unintelligible， or at the very least contains a hidden assum ption that the world is non－local，an assum ption which com pletely escaped the physicists who rst developed the theory（because they did not understand what they were doing？）．This despite the fact that all predictions of standard quantum $m$ echanics seem am ply supported by every experim ental test designed to uncover some aw．

A s a second exam ple，consider the recent assertion by Englert et al．［7］that B ohm ian $m$ echanics 目，目］$m$ akes predictions（or at least retrodictions）which disagree $w$ th the results of standard quantum $m$ echanics and also $w$ ith com $m$ on sense：detectors designed to detect particles passing through them can actually be triggered by particles which，according to the Bohm ian interpretation，never com e close to the detector．O ne might have im agined that this observation would have prom pted advocates of Bohm ian m echanics to w ithdraw or m odify their claim［7］that this theory reproduces all the results of standard quantum m echanics，especially given an independent veri cation［］］of the essential correctness of the calculations by Englert et al．Instead，the response 园，［］has been that standard quantum $m$ echanics，in contrast to Bohm ian mechanics，does not provide an adequate theoretical fram ew ork for sensibly discussing whether the particle passed through the detector；thus one m ust take the B ohm ian result seriously，as the precise outcom e of a well－de ned theory， how ever counterintuitive it $m$ ay appear to be．

The ultim ate goalofthe research reported in the present article is to place non－relativistic quantum $m$ echanics on as $m$ and precise a conceptual foundation as that of special rel－ ativity．This is not as ambitious a project as $m$ ight at rst seem to be the case，for two reasons．First，a large part of non－relativistic quantum theory is already in a quite sat－ isfactory state，at least by the som ew hat lax standards of theoretical physics．The basic conceptualdi culties are focused in a sm all（but critical）area，the point at which the $m$ ath－ em atical form alism of Schrodinger＇s equation，H ibert space operators，and the like，which by now is quite well understood，is used to generate the probabilities needed to com pare theoretical predictions w ith experim ental results．Second，a set of ideas which seem to be adequate for integrating the probabilistic and determ in istic aspects of quantum theory into a coherent whole are already in the published literature，although their signi cance has not been widely appreciated．The rst of these ideas is von $N$ eum ann＇s form ulation of quantum theory using closed subspaces of H illbert space to represent quantum properties［10］｜to be carefully distinguished from his theory ofm easurem ents 11］and his proposal（together w th B irkho ）of a special quantum logic［12］，neither of which are em ployed in the form ulation
of quantum theory presented here. N ext com es the concept of a consistent history 13], followed by Om nes' proposal that quantum reasoning must involve separate \logics" 14], and the G ell-M ann and H artle decoherence functional [15]. To this list the present article adds one new idea, or at least a new w ord: the fram ew ork in which a classical or quantum description is em bedded, and relative to which its truth $m$ ust be assessed.

A fram ew ork corresponds to a consistent fam ily in the notation of [13], or a \logic" in the notation of [14]. It is closely related (but not identical) to the concept of an \interpretation" in $m$ athem atical logic 16]. The key to $m$ aking sense out of the description of a quantum system, either at a single tim e or as it develops in tim $e$, is to note that such a description cannot be $m$ ade $w$ ithout adopting, at least im plicitly, som e fram ew ork; that the truth of such a description is relative to its fram ew ork; and that reasoning in the quantum dom ain requires the use of com patible fram ew orks. A ll of these concepts can be m ade quite precise, and using them should help clear up (what I regard as) som em isunderstandings, and respond to various criticism s of the consistent history program [17, 18, [19].

The present work is very much indebted to 0 m nes' ideas [14]. A crucial di erence is that the notion of $\backslash$ truth" is $m$ ade to depend explicitly on the fram ew ork, follow ing certain classical analogies, Sec. II A, and the exam ple of form al logic. By contrast, 0 m nes de ned \truth" in term s of \facts" which arise in a quasi-classical approxim ation, Sec. $V \mathrm{D}$. . The latter does not seem an entirely satisfactory approach for a fiundam ental theory of nature, and certain criticism s have been made by d'E spagnat [18], and by D ow ker and K ent 19]. O m nes him self [20] agrees that his approach has som e problem s.

The conceptual structure presented in this paper appears adequate to support the position of Englert et al. [4] (the argum ents are not presented here), and to nd the $m$ istakes (from the perspective of standard quantum mechanics) in at least som e derivations of $B$ ell's inequality; 21]. There are other derivations of $B$ ell's inequality which rest upon counterfactual reasoning: what would have happened if som ething had been di erent; in addition, $m$ any quantum paradoxes involve a counterfactual elem ent. A nalyzing these will require an extension of the ideas discussed here; see Sec. VIB.

W hile its m ain goal is the clari cation of conceptual issues through the introduction of suitably precise rules of reasoning in the quantum dom ain, this paper also contains, in Sec. IV, som e new results on quantum histories and consistency conditions. The representation of histories through the use of pro jectors on tensor products of copies of the H ibert space seem s to be a new idea, and the notion of a \generalized" history based upon this representation includes, but also goes well.beyond, previous proposals by the author [13, 22], Om nes [14], and G ell-M ann and $H$ artle [15]. The \consistency functional" introduced in the sam e context generalizes the \decoherence functional" of Gell M ann and H artle [15], and results in a form ulation of fundam ental quantum theory which is (transparently) invariant under reversing the direction of tim e.

P hilosophical issues are not the $m$ ain topic of this paper. H ow ever, its central argum ent provides a num ber of details supporting a proposal, found in an earlier publication 23], for interpreting quantum $m$ echanics in a \realistic" $m$ anner.

M any of the crucial features which distinguish quantum reasoning from its classicalcountenpart already arise when one considers a single $m$ echanical system at a single instant of time. H ence Secs. II and III, in which the quantum description of a system at one time is developed w th the help of classical analogies, form the heart of this paper. In particular,
discussing both classical and quantum system $s$ from the sam e point of view helps avoid the error of supposing that the latter som ehow involve a subjective elem ent not present in the form er, while bringing out the genuine di erences between the reasoning processes appropriate in the two situations.

D escribing how a quantum system evolves in time tums out to be, form ally at least, very sim ilar to describing its properties at a single tim e if one em ploys the technical tools in Sec. IV , which allow a history to be represented by a single projector on a tensor product space. T he notion of consistency has, to be sure, no counterpart in a system at a single tim e, and discussing it in a precise and general way makes Sec. IV m ore com plicated than the other parts of the paper. The reader who is unfam iliar with the use of consistent histories in quantum mechanics should look elsew here [13, 14, 22] for a discussion of the physical $m$ otivation behind the consistency requirem ent, and sim ple exam ples of its use.

The applications in Sec. V can be understood w ithout the technicalm achinery of Sec. IV if the reader is $w$ illing to accept various results on faith; the proofs are, in any case, not included in this paper. These exam ples are not new (except, perhaps, for the discussion of tw o-slit di raction), but have been chosen to ilhustrate the form ulation ofquantum reasoning introduced earlier in the paper. Sec. V I contains a sum mary of this form ulation, together w th a list of open questions.

## II C lassical $R$ easoning

## II A Fram ew orks and D escriptions

A scienti c description of a physical system is, at best, an abstract, sym bolic representation of reality, or of what the scientist believes that reality to be; the description is never reality itself. Thus it necessarily embodies certain elem ents of hum an choice. N onetheless, at least in the \classical" world of our everyday experience, it is not unreasonable to claim that such a description is, or at least $m$ ight be, a fathful or \true" representation of reality. U nderstanding the process ofdescription in the classical realm w illassist us in understanding how elem ents ofchoioe can enter quantum descriptions w ithout necessarily $m$ aking them any less \ob jective" than their classical counterparts.

A s a rst exam ple, consider representing a three-dim ensional ob ject, such as a vase, by $m$ eans of a two-dim ensional draw ing which show s a pro jection of the ob ject on a particular plane. It will be convenient to refer to the choioe of projection plane and the various conventions for representing salient features of the ob ject in the draw ing as a fram ew ork $F$, and the draw ing itself as a statem ent, f, with the pair ( $F$;f) constituting a description of the ob ject. The follow ing are obvious properties of such descriptions:

1. A fram ew ork is chosen by the person $m$ aking the description, and $w$ ithout such a choige no description is possible.
2. C hoosing a fram ew ork has, by itself, no in uence on the ob ject being described; on the other hand $\mathbb{I}$ constrains what can correctly be said about the ob ject. (Features which are visible in one projection $m$ ay well be invisible in another.)
3. A fram ew ork by itself is neither true nor false. A statem ent can be true (ie., a correct representation of the ob ject) or false, but to determ ine which it is, one m ust know the corresponding fram ew ork. T hat is, truth or falsity is relative to the fram ew ork.
4. The correctness of a description can be tested experim entally. (For exam ple, the distance betw een two points on the draw ing can be checked by m easuring the distanœe between the corresponding features on the ob ject, provided one know s the pro jection plane and the scale of the draw ing.)
5. A n arbitrary collection ofdescriptions, each ofw hich applies individually to the ob ject, can alw ays be thought of as parts of a collective or com posite description of the ob ject.

A part from the comments in parentheses, every item in this list, with the sole exception of 5, also applies to a quantum description! That is, quantum descriptions are no less \ob jective" or \realistic" than their classical countenparts. H ow ever, they are di erent (reecting, one $m$ ight suppose, the peculiar nature of quantum reality) in that it is not alw ays possible to com bine various descriptions which might separately apply to a particular ob ject into a single com posite description. This feature has no classical analog (that we know of), and hence understanding what it $m$ eans is essential for consistent quantum reasoning. In particular, one needs an appropriate $m$ athem atical form alism, discussed in Secs. III and IV below, giving the precise rules for combining (or not com bining) quantum descriptions, and reasoning about them, together with exam ples, of which there are som e in Sec. V , which illustrate the rules.

Each of the ve points in the preceding list can be illustrated using as an exam ple the intrinsic angular $m$ om entum or spin, $m$ easured in units of $\sim$, ofa spin $1 / 2$ quantum particle. O ne possible description, which em ploys the x com ponent of the spin, has the form :

$$
\begin{equation*}
\left(S_{x} ; 1=2\right) ; \tag{1}
\end{equation*}
$$

$w$ here $S_{x}$ is the fram ew ork and $1=2$ is the statem ent. Together they form the description usually w ritten as $S_{x}=1=2$. A nother equally good description is:

$$
\begin{equation*}
\left(S_{x} ; \quad 1=2\right) ; \tag{2}
\end{equation*}
$$

or $S_{x}=1=2$. Because (1) and (2) em ploy the same fram ew ork, the same (fram ew ork dependent!) notion of (truth" applies to both. In fact, if (1) is true, (2) is false, and vice versa. Choosing the fram ew ork $S_{x}$, i.e., choosing to talk about $S_{x}$, does not $m$ ake $S_{x}=1=2$ true or false, in fact, it has no e ect whatsoever on the spin of the particle. H ow ever, such an assertion is sub ject to experim ental veri cation (or falsi cation) \in principle", that is to say, in term $s$ of idealized experim ents which, while they $m$ ay not be practical, at least do not violate the principles of quantum theory itself. T hus we $m$ ight im agine that the spin $1 / 2$ particle is a neutron traveling slow ly tow ards a Stem-G erlach apparatus whose $m$ agnetic eld gradient is in the $x$ direction, equipped $w$ ith a pair of counters to determ ine the channel in which the neutron em erges. If the neutron later em erges in the $+1=2$ channel, that will verify the correctness of the description $S_{x}=1=2$ at the present tim e, before the neutron enters the eld gradient. Even the \classical" problem ofchecking a two-dim ensional projection of a three-dim ensional object by $m$ aking $m$ easurem ents on the object requires a
certain theoretical analysis: relating the distance between two points on the draw ing to the $m$ easured distance between the corresponding features on the ob ject requires know ing both the pro jection plane and the scale factor of the draw ing, and using som e trigonom etry. Sím ilarly, experim ental veri cation of a quantum description requires an appropriate theory ofm easurem ent, as discussed in Sec.V A.

W e now come to item 5 in the list. T he description

$$
\begin{equation*}
\left(S_{z} ; \quad 1=2\right) ; \tag{3}
\end{equation*}
$$

or $S_{z}=1=2$, which uses the $z$ com ponent of the spin, is on a par with (1) or (2). It sim ply represents a \projection" of the particle's angular mom entum on a di erent axis. W ere we dealing $w$ th a classicalspinning ob ject there w ould be not the slightest problem in com bining its various com ponents of angular $m$ om entum into a com plete description corresponding to a three-dim ensional vector. But in the quantum case, the fram ew orks $S_{x}$ and $S_{z}$ are incom patible, a term which will later receive a precise de nition, and as a consequence one of the basic rules of quantum descriptions asserts that there is no way to com bine $S_{x}=1=2$ and $S_{z}=1=2$ into a single description. $N$ ote that this is not the assertion that if $S_{x}=1=2$ is \true", then $S_{z}=1=2$ is \false". Truth and falsity are concepts relative to a particular fram ew ork, and in the case of descriptions using $S_{x}$ and $S_{z}$, there is no single fram ew ork in which a com $m$ on notion of truth can be applied to both of them .

The issue of com patibility of fram ew orks arises because standard quantum mechanics, unlike classical mechanics, em ploys a H ilbert space, rather than a classical phase space, for descriptions. Incom patibility re ects the fact that certain operators do not com $m$ ute $w$ th each other, a peculiarly quantum phenom enon. In term $s$ of a spin $1 / 2$ particle, the $H$ ilbert space structure $m$ anifests itself in the follow ing way. D escriptions (1), (2), and (3) correspond, as is well known, to particular one-dim ensional subspaces or rays of the twodim ensional $H$ ibert space $H$ which represents the spin of the particle; in fact, they are the subspaces spanned by the corresponding eigenvectors of the operator $S_{x}$ or $S_{z}$. B ut as there are no sim ultaneous eigenvectors of $S_{x}$ and $S_{z}$, there are no subspaces of $H$ which $m$ ight be thought of as corresponding to $S_{x}=1=2$ and $S_{z}=1=2$, that is, to the conjunction of these two descriptions. A nother way of thinking about the $m$ atter is to note that in classical $m$ echanics, specifying the $z$ com ponent of angular $m$ om entum provides additional inform ation beyond that obtained through specifying the $x$ com ponent, whereas for a spin $1 / 2$ particle one cannot specify any inform ation in addition to $S_{x}=1=2$, which is already a pure state.

It is helpfulto think of a fram ew ork, classicalor quantum, as de ning a \topic of conversation" and, just as in ordinary conversation, in scienti c discourse the fram ew ork is often chosen im plicitly. The phrase \oranges cost 25 cents each at the superm arket" both de nes a topic of conversation and sim ultaneously asserts som ething about the nature of the world, and the sam $e$ is true of $\backslash S_{x}=1=2 \prime$ ". W hile it is hard to im agine any e cient schem e of scienti c com m unication which did not de ne fram ew onks im plicitly most of the tim $e$, it is som etim es helpful, especially in the quantum case, to re ect upon just what fram ew ork is being used at som e point in a discussion, as this can help avoid the nonsensical statem ents and generalconfusion which arises when an invalid change of fram ew ork occurs in the m iddle of an argum ent.

## II B C lassical P hase Space

The usual fram ew ork for discussing a classicalm echanical system of $N$ particles at a single instant of tim e is provided by its 6 N -dim ensional phase space D , in which a single point $x$ represents the state of the system at the tim e in question. A statem ent p, such as: \the total energy is betw een 10 and 11 ergs", can then be thought of as associated w ith the subset

$$
\begin{equation*}
P={ }^{\prime}(p) \tag{4}
\end{equation*}
$$

of points in $D$ where $p$ is true, that is, the set contained betw een two surfaces of constant energy, one at 10 ergs and the other at 11 ergs. The negation ofp, denoted $p$, corresponds to $D r P$, the com plem ent ofP in $D$, the region in the phase space forw hich the energy is less than 10 ergs or greater than 11 ergs. A nother statem ent q: \there are exactly 35 particles in the volum e elem ent $V_{1}$ ", where $V_{1}$ denotes som e de nite region in three-dim ensional space, corresponds to the subset $\mathrm{Q}={ }^{\prime}(\mathrm{q})$ of D . The conjunction of p and q , \energy between 10 and 11 ergs and 35 particles in $V_{1}$ ",w ritten $p^{\wedge} q$, corresponds to the intersection $P \backslash Q$ of the sets $P$ and $Q$. Thus one sees that various lelem entary" statem ents which describe properties of the system can bem apped onto subsets ofD, and other \com posite" statem ents form ed from the elem entary statem ents by use of the logical operations \not", \and", \or", denoted respectively by $;^{\wedge}$; , are then also $m$ apped to subsets of $D$ using complem ents, intersections, and unions of the sets corresponding to the elem entary statem ents. N ote that under the operations ofcom plem ent, union, and intersection, the subsets ofD form a B oolean algebra B .

It will be convenient to think of the fram ew ork F as consisting of elem entary and com posite statem ents, together w th the set D, the B oolean algebra B of its subsets, and the function' which $m$ aps the statem ents onto elem ents of $B$. A description ( $F$; $f$ ), where $f$ is one of the statem ents, corresponds to the assertion that the state of the $m$ echanical system is one of the points in the subset $F='(f)$, and is true or false depending upon whether the point $x$ corresponding to the actual state of the system at the tim $e$ in question is or is not in $F$. N ote that $m$ any di erent statem ents $m$ ay correspond to the sam e $F$; for exam $p l e, p-p$ for any statem ent $p$ is $m$ apped onto the entire phase space $D . W$ hen it is not im portant to distinguish the di erent possibilities corresponding to som e F , one m ay use a description ( $F$; $F$ ), w ith $F$ a surrogate for any statem ent which is $m$ apped onto it by ${ }^{\prime}$.

A description form ed in this way is what in rst-order predicate logic [16] is called an interpretation. For our purposes it su ces to sum $m$ arize the rules of logical reasoning, $m$ odus ponens and the like, as applied to descriptions of our classical m echanical system, in the follow ing w ay. T he logical process of inference from a set of assum ptions to valid conclusions consists in taking the intersection, let us call it A, of all the subsets ofD corresponding to all of the assum ptions| if one prefers, A is the im age under' of the single statem ent consisting of the conjunction ( $\backslash$ and") of all the assum ptions. Then any conclusion which corresponds to a subset C ofD which contains A is a valid conclusion from these assum ptions. That is to say, logical reasoning in this context is the process of checking that if there is any $x$ in $D$ for which all the assum ptions are true, then for this $x$ the conclusion will also be true. N ote that the process of inference can begin with no assum ptions at all, in which case one sets A equal to $D$, and a valid conclusion is a tautology, such as p_ $p$.

## III Quantum System s at O ne Time

## III A Q uantum Fram ew orks

The counterpart for a quantum system of the classical phase space $D$ is a $H$ ibert space $H$, and an elem entary statem ent $p$ which ascribes to the quantum system a property at a particular time is associated with a closed subspace $P$ of $H$ or, equivalently, the projector (orthogonalpro jection operator) $P$ onto this subspace. For exam ple, ifp is the assertion that \the totalenergy is between 10 and 11 ergs", the subspace $P$ is spanned by the eigenvectors of H w ith eigenvalues (assum ed, for sim plicity, to be discrete) which lie between 10 and 11 ergs. The negation $p$, which asserts that the energy lies outside this interval, corresponds to the orthogonal com plem ent $P$ ? of $P$ (not to be confiused with H rP), w ith projector I P , where I is the identity operator on H .

A fram ew ork $F$ in the quantum case is generated by a nite collection of elem entary statem ents associated w ith pro jectors onto closed subspaces of H provided these projectors commute with each other. The projector associated with a statem ent p will be denoted by ' (p). The additional statem ents belonging to $F$ are produced from the elem entary statem ents using logical operations, as discussed in Sec. II, and are mapped by ' onto projectors consistent w the the rules

$$
\begin{equation*}
\left.\prime(p)=I \quad{ }^{\prime}(p) ; \quad{ }^{\prime}\left(p^{\wedge} q\right)=\right)^{\prime}(p)^{\prime}(q): \tag{5}
\end{equation*}
$$

(T hese rules su ce, because every logicaloperation can be buitt up using \not" and \and".) The sm allest fam ily B of commuting projectors closed under com plem ents and products, and containing the projectors associated w ith the statem ents of F , is a Boolean algebra in which the operations of $\backslash$ and [ , thought of as acting on pairs of pro jectors, are de ned by

$$
\begin{equation*}
P \backslash Q=P Q ; P \quad[Q=P+Q \quad P Q ; \tag{6}
\end{equation*}
$$

and whose least and largest elem ents are ; (the zero operator) and I, respectively. The fram ew ork F can then be de ned as the collection of statem ents generated from a set of elem entary statem ents by logicaloperations, along $w$ ith the $H$ ilbert space $H$ and them apping ' which carries statem ents onto the Boolean algebra B of commuting projectors in the $m$ anner indicated above.

A quantum description ( $F$; f) consists of a fram ew ork $F$ and a statem ent $f$ belonging to the collection of statem ents associated with F. Som etim es it is convenient to use a description ( $F ; F$ ), where the projector $F$ is an elem ent of the B oolean algebra B associated $w$ th $F$, and serves as a surrogate for any $f m$ apped to this $F$ by'. As long as $F$ is held xed, there is a close analogy w ith classical descriptions based upon a phase space as discussed in Sec. II B above. Since all the projectors in the Boolean algebra B associated w ith F commute w ith each other, it is possible to choose a representation in which they are sim ultaneously diagonal, which $m$ eans that each diagonal elem ent hjf jiji of a projector $P='(p)$ in $B$ is either 0 or 1 . If one thinks of the set of labels $f j g$ of the diagonalelem ents as constituting a set $D$, then the subset of $D$ where hjp $j i=1$ is analogous to the set of points in the classical phase space $D$ where the statem ent $p$ is true. T his analogy w orks very well as long as F is held xed, and perm its one to construct the nules for quantum reasoning in close analogy w ith their classical countenparts.

In particular, one thinks of a quantum description ( $F ; p$ ) as true provided the quantum system at the time in question is $\backslash$ in" the subspace onto which $P='(p)$ projects. To be more precise, if we assume that any projector B belonging to the Boolean algebra B associated with F represents a statem ent about, or property of the quantum system which is true at the time in question, then this im plies the truth of any statem ent $s$ w th the property that

$$
\begin{equation*}
B S=B ; \tag{7}
\end{equation*}
$$

where $S=$ ' (s) is the projector corresponding to $s$, that is, provided the subspace onto which B projects is contained in the subspace onto which S projects. Just as in the case of the classical descriptions discussed in Sec. $\prod_{\text {, the }}$ the truth of a quantum description must always be thought of as relative to a fram ew ork, which $m$ ay have been de ned im plicitly. Hence it is best to think of $\backslash(F ; f)$ is true" as meaning: \G iven $F$, then $f$ is true."
$Q$ uantum reasoning w ithin the context provided by a single fram ew ork F proceeds in the follow ing way. The assum ptions of the argum ent, $a_{1} ; a_{2} ;::: a_{1}$, which $m$ ust allbe statem ents belonging to F , are m apped by ${ }^{\prime}$ onto a set ofpro jectors $\mathrm{A}_{1} ; \mathrm{A}_{2} ;::: \mathrm{A}_{1}$ belonging to B , whose product is:

$$
\begin{equation*}
A=A_{1} A_{2} \quad 1: A \tag{8}
\end{equation*}
$$

$T$ hen a statem ent C in F is a valid conclusion provided $\mathrm{AC}=\mathrm{A}$, where $\mathrm{C}={ }^{\prime}$ (c).

## III B C om patible and In com patible Fram ew orks

The most im portant di erences between classical and quantum descriptions em erge when one considers several di erent fram ew orks. In the classical case, as long as the fram ew orks refer to the sam e system, there is no problem in combining the corresponding descriptions. But in the quantum case this is no longer true, and it is necessary to pay attention to the rules which state when descriptions can and cannot be com bined.

A nite collection of fram ew onks $f F_{i} 9 ; i=1 ; 2 ;::: 1, w$ illbe said to be (m utually) com patible ifeach fram ew ork em ploys the sam e H ilbert space H, and if all the pro jectors associated $w$ ith the di erent Boolean algebras $B_{i}$ com $m$ ute $w$ ith one another. In addition, the state$m$ ents belonging to the di erent fram eworks should be mapped onto the projectors in a consistent way, so that an elem entary statem ent which occurs in $m$ ore than one fram ew ork ism apped to the sam e pro jector. (T his last point is a $m$ atter ofnotational consistency which causes little di culty in practioe.) G iven a com patible collection fF ${ }_{i} 9$ there is a sm allest fram ework F which contains them all: its statem ents are generated from the union of the sets of elem entary statem ents for the individual $\mathrm{F}_{\mathrm{i}}$, and its B oolean algebra B of pro jectors is the sm allest one containing all the pro jectors of all the Boolean algebras $\mathrm{B}_{\mathrm{i}}$ associated w ith the di erent fram ew orks in the collection. W e shall say that the com patible collection $\mathrm{fF}_{\mathrm{i}} \mathrm{g}$ generates this sm allest fram ew ork F .

Two orm ore fram ew orks which are not com patible are called incom patible. T he distinctive problem s associated with quantum reasoning arise from the existence of fram ew orks which use the sam e H ibert space, and can thus (potentially) refer to the sam e physical system, but which are mutually incom patible because the projectors associated with one fram ew ork do not com $m$ ute w ith those of another. There is nothing quite like this in classical $m$ echanics, since the classical counterparts of projectors alw ays com $m$ ute $w$ ith one
another.
W e adopt the follow ing as a fundam ental rule. A m eaningfiulquantum description $m$ ust consist of a single fram ework and one of its statem ents, ( $F$; f), or else a com patible collection of fram ew orks $\mathrm{fF}_{\mathrm{i}} \mathrm{g}$ and associated statem ents $\mathrm{ff}_{\mathrm{i}} \mathrm{g}$, which together form a collective description $f\left(F_{i} ; f_{i}\right) g$. A collective description can alw ays be replaced by a single $m$ aster description (D; d ), where D is the fram ew onk generated by the collection $\mathrm{fF}_{\mathrm{i}} \mathrm{g}$, and d is any statem ent such that

$$
\begin{equation*}
D={ }^{\prime}(\mathrm{d})=\mathrm{F}_{1} \mathrm{~F}_{2} \quad 1 \mathrm{~F} \tag{9}
\end{equation*}
$$

is the product of the projectors $F_{i}=$ ' $\left(f_{i}\right)$ corresponding to the di erent statem ents.
The rules for logical reasoning about quantum descriptions are sim ilar to the rules for reasoning about classicaldescriptions, but $w$ ith the additional requirem ent that all the fram $e^{-}$ works m ust be com patible. A logical argum ent begins w ith a a set of assum ptions, which is to say a set of descriptions $f\left(A_{i} ; a_{i}\right) g ; i=1 ; 2 ;::: 1$, associated w ith a com patible fam ily $f A_{i} g$ of fram ew orks; one is assum ing that these descriptions are sim ultaneously true (w ithin the fram ew ork generated by the collection $\mathrm{fA}_{\mathrm{i}} \mathrm{g}$ ). From these assum ptions one can deduce a set of valid conclusions $f\left(C_{j} ; C_{j}\right) g ; j=1 ; 2 ;::: m$, provided the union of the collections $\mathrm{fA}_{\mathrm{i}} \mathrm{g}$ and $\mathrm{fC}_{j} \mathrm{~g}$ is a com patible collection of fram ew orks, and

$$
\begin{equation*}
'\left(C_{j}\right) A=A ; \tag{10}
\end{equation*}
$$

holds for every $j$, where

$$
\begin{equation*}
\mathrm{A}=\mathrm{A}_{1} \mathrm{~A}_{2} \quad 1 \mathrm{~A} \tag{11}
\end{equation*}
$$

is the product of the projectors $A_{i}='\left(a_{i}\right)$. The set of assum ptions can alw ays be replaced by the corresponding $m$ aster description acting as a single assum ption, since the process of reasoning just described allow s one to deduce the original set of assum ptions from this $m$ aster description. A valid argum ent can begin $w$ th the true assum ption ( $F ; I$ ), where $F$ is any fram ework, and I is the identity operator.

It is extrem ely im portant that w thin a single argum ent, all the fram ew orks, for both the assum ptions and conclusions, be com patible. In particular, the follow ing sort of \quasiclassical reasoning", $m$ any exam ples of which are to be found in the published literature, is not valid: O ne starts w ith an assum ption ( $\mathrm{A} ; \mathrm{a}$ ), and from it deduces a conclusion ( $\mathrm{C} ; \mathrm{c}$ ), after checking that the fram ew orks A and C are com patible. Next, ( $C$; C) is used as the assum ption in an argum ent whose conclusion is (E;e), again after checking that the fram eworks $C$ and $E$ are com patible. Combining these two argum ents one draws the conclusion that \is a is true, then em ust be true". But this reasoning process is only correct ifA and E are com patible fram ew orks; if they are incom patible, it is invalid. (N ote that com patibility is not a transitive relationship: A can be com patible w ith C and C w ith E at the sam e tim e that A is incom patible w th E.) Failure to check com patibility can easily lead to inconsistent quantum reasoning which, just like inconsistent classical reasoning, often produces contradictions and paradoxes. In order to avoid $m$ aking $m$ istakes of the sort just described, it is helpful to think of a single quantum argum ent as a process in which the assum ptions, which them selves form a (collective) description, are extended into a longer and longer collective description by adding additional sm ple descriptions w ithout ever erasing anything; in particular, w ithout forgetting the original assum ptions. The com patibility rule for collective quantum descriptions $w$ ill then rule out any attem pt to introduce incom patible fram ew orks.

On the other hand, two or m ore separate argum ents $m$ ay very well involve di erent, and perhaps incom patible fram ew orks. But then they cannot be combined into a single argum ent. A s an exam ple, it is possible to construct two perfectly valid argum ents, each based upon the sam e assum ption ( $A$; a), one leading to the conclusion ( $C$; $c$ ) and the other to the conclusion ( $E ;$ e), where the fram ew orks $C$ and $E$ are incom patible. If one grants the truth of the assum ption, then $c$ is true relative to fram ew ork $C$, and $e$ is true relative to fram ew ork E. H ow ever, there is no fram ew ork relative to which it can be said that both c and e are true statem ents. $G$ iven a particular physical system for which the assum ptions are satis ed, it is possible in principle to chedk the validity of either c or e by m eans of $m$ easurem ents, but not (at least in general) the validity of both. An exam ple (involving histories) which illustrates this point w ill be found in Sec. V B below .

If one wishes to describe a quantum system, it is necessary to choose a fram ew ork, if only im plicitly, and in all but the $m$ ost trivial cases this choice $m$ eans that there are $m$ any incom patible fram ew orks whose statem ents cannot be em ployed in the description. W hile the choice of a fram ew ork does not in any way \in uence" the system being described, Sec. II A, it severely constrains what can sensibly be said about it. Thus if one wants to talk about the energy, this requires the use of certain pro jectors, depending on how precisely one wants to specify the energy, and what ranges one is interested in. It is then not possible, as part of the sam e description, to talk about som ething else represented by projectors which do not com $m$ ute $w$ ith the set em ployed for the energy.

The type of exclusion which arises from incom patible fram ew orks is easily confused w ith, but is in fact quite di erent from the sort of exclusion which arises all the tim e in classical $m$ echanical descriptions, where in order that som e property p be true, it is necessary that som e other property $q$ be false (because the corresponding subsets of the classical phase space do not overlap, Sec. II B). This \classical" type of exchusion also arises in quantum system $s$ where, to take the exam ple of a spin $1 / 2$ particle, $\backslash S_{x}=1=2$ " and $\backslash S_{x}=1=2$ " are $m$ utually exclusive statem ents belonging to the sam e fram ew ork: if one is true, the other is false.

By contrast, if $p$ and $q$ are assertions about a particular quantum system represented by projectors $P$ and $Q$ which do not commute, they cannot be part of the same fram ew ork. Hence in a fram ework $P$ in which it makes sense to talk about the truth and falsity of $p$, there is no way of discussing whether $q$ is true or false, since $w$ ithin this fram ew ork $q$ $m$ akes no sense. C onversely, in a fram ew ork $Q$ in which $q m$ akes sense, and could be true or false, $p$ has no $m$ eaning. Thus the truth of $p$ does not $m$ ake $q$ false; it does $m$ ean that because we have (perhaps im plicitly) adopted a fram ew ork in whidh it m akes sense to talk about $p$, $q$ cannot be discussed. Sim ilarly, the com bination $p^{\wedge} q$, or $\backslash p$ and $q "$, is not part of any fram ew ork, and therefore cannot be true or false. It is $\backslash \mathrm{m}$ eaningless" in the sense that within quantum theory one cannot ascribe any m eaning to it. In $m$ athem atical logic there are certain com binations of sym bols, for exam ple p^_q, which are \nonsense" because they are not \well-form ed form ulas", they are not constructed according to the rules for com bining sym bols of the language to form $m$ eaningfiul statem ents. In the quantum case, where the rules are, of course, di erent from those of classical logic, $p^{\wedge} q$ (and also $p, q$, etc.) has this nonsensical character when $P Q \in P$.

## IV Q uantum System $s$ at $M$ any $T$ im es

## IV A C lassical A nalogy

A classical stochastic process, such as rolling a die several tim es in succession, is a more usefiul analogy to quantum tim e dependence than is a continuous trajectory in a classical phase space. If a die is rolled three tim es in succession, the possible outcom es are triples of num bers $\left(d_{1} ; d_{2} ; d_{3}\right) ; 1 d_{j} 6$, which together constitute the set

$$
\begin{equation*}
D^{\sim}=D^{3} \tag{12}
\end{equation*}
$$

of $216=6^{3}$ histories, the sam ple space of classical probability theory. Here $D$ is the set of possible outcom es of one toss. A statem ent such as p: \the sum of the rst two tosses is four", is associated w th the subset $P^{r}=$ ' (p) of $D^{r}$ consisting of those histories for which $p$ is true. The process of logical inference em ploying statem ents of this kind is then form ally identical to that discussed in Sec. II.B. For exam ple, from $p$ one can im m ediately infer $r$ : \the sum of all three tosses is ve orm ore" by noting that $P^{r}$ is a subset of $R='(r)$, the set of histories where $r$ is true.

On the other hand, the statem ent q: \the sum of all three tosses is exactly seven", is not a logical consequence of $p$, since $\widetilde{Q}={ }^{\prime}(q)$ is a subset of $p$. H ow ever, if probabilities are assigned to $D^{\prime}$, one can com pute the conditional probability

$$
\begin{equation*}
\operatorname{Pr}(q j p)=W \quad\left(\widetilde{Q} \backslash P^{\sim}\right)=W \quad\left(\mathbb{F}^{\prime}\right) \tag{13}
\end{equation*}
$$

of $q$ given $p$, using weights $W(\mathbb{A})$ for subsets $\mathbb{A}$ of $D^{r}$. In the case of an unloaded die, W ( $\mathbb{A}$ ) is just the num ber of elem ents (histories) in the set $\mathbb{A}$. On the other hand, $m$ aking appropriate replacem ents in (13), one sees that $\operatorname{Pr}(\mathrm{r} j \mathrm{j})=1$. Indeed, as long as every history has a nite weight, there is a close connection between $r$ being a logical consequence of $p$, and $\operatorname{Pr}(r j p)=1$; the only di erence com es about in the case in which the statem ent $p$ corresponds to an em pty set w ith zero weight, for which the right side of (13) is unde ned.

## IV B H istories and P ro jectors

The sm plest type of history for a quantum system with $H$ ilbert space $H$ is constructed in the follow ing way. Let a nite set of tim es $t_{1}^{0}<t_{2}^{0}<\quad f_{j}^{f}$ le given, and at each $t_{j}^{0}$ let $P_{j}^{0}$ be a pro jector onto a closed subspace of $H$. The history consists of the set of tim es and the associated projectors, representing properties of the system which are true at the corresponding tim es. So that this history can be discussed within the sam e fram ew ork as other histories de ned at di erent sets of tim es, it is convenient to suppose that there is a com $m$ on set of tim es

$$
\begin{equation*}
t_{1}<t_{2}<\quad n<t \tag{14}
\end{equation*}
$$

su ciently large to include all those associated w ith the di erent histories in the fram ew ork, and that a particular history is represented by a sequence of pro jectors $\mathrm{P}_{1} ; \mathrm{P}_{2} ;::: \mathrm{P}_{\mathrm{n}}$, one for each of the tim es in (14). To do this, $P_{k}$ is set equal to the identity $I$ if $t_{k}$ is not one of the tim es for which the history was originally de ned, and to $P_{j}^{0}$ if $t_{k}=t_{j}^{0}$. Since the \property" represented by $I$ is alw ays true, it $m$ ay be \added" to the originalhistory at additionaltim es w thout m odifying its physical signi cance.

R ather than representing a history w ith a sequence of pro jectors $\mathrm{P}_{1} ; \mathrm{P}_{2} ;::: \mathrm{P}_{\mathrm{n}}$, it is technically m ore convenient to em ploy a single projector

$$
\begin{equation*}
P^{\sim}=P_{1} \quad P_{2} \quad{ }_{n} P \tag{15}
\end{equation*}
$$

on the tensor product space

$$
\begin{equation*}
\mathrm{H}^{\sim}=\mathrm{H} \quad \mathrm{H} \quad \mathrm{H} \tag{16}
\end{equation*}
$$

of $n$ copies of $H$, which is analogous to $D \sim$ in the classical case discussed earlier. It is obvious that if each of the $P_{j}$ on the right side of (15) is a projector, so is $\mathrm{P}^{2}$; on the other hand, not every projector on $\mathrm{H}^{\text {r }}$ has the form (15). It will be convenient to extend the concept of a history to include any projector on H . T he resulting category of generalized histories is large enough to include the proposalsm ade by O m nes [14] ( $\backslash n o n-G$ ri ths histories"), and by G ell-M ann and H artle [15] ( $\backslash$ history-dependent decom positions of the identity"), and m uch else besides. H ow ever, the applications discussed in Sec. V are all of the restricted form (15), hereafter referred to as sim ple histories.

A fram ew ork $F$ for the case ofm any tim es can be constructed in the follow ing way. We suppose that there are a nite num ber of elem entary statem ents p;q;::: and that to each of these there corresponds a projector on $\mathrm{H}^{\text {r }}$, representing some (generalized) history. As in the case of a quantum system at one tim e, we require that all these pro jectors com $m$ ute $w$ ith each other. They are therefore $m$ em bers of a sm allest B oolean algebra $B^{\sim}$ of com $m$ uting projectors closed under the operations of products and com plem ents, where $I T$ is the com plem ent of $P^{\sim}$, and

$$
\begin{equation*}
I=I \quad I \quad I \tag{17}
\end{equation*}
$$

is the identity on $\mathrm{H}^{\sim}$. Additional statem ents form ed from the elem entary statem ents by logical operations will also be m apped onto elem ents of $\mathrm{B}^{\sim}$ follow ing the rules in (5). T hus the structure is form ally the sam e as that in Sec. III. H ow ever, for a fram ew ork involving histories to be acceptable it m ust also satisfy consistency conditions, which is the next topic.

## IV C C onsistency and W eights

V arious consistency conditions have been proposed by various authors; w hat follow s is closest in spirit to [22], while very m uch indebted to the ideas in [15]. In the follow ing discussion it $w$ illbe convenient to assum e that the $H$ iblbert space $H$ is nite dim ensional, so that there are no questions about convergence of sum $s$. This $w i l l$ not bother low forow physicists who are quite content to consider a quantum system in a box of nite volum e w ith an upper bound (as large as one w ishes) on the energy. Extending the form alism in a $m$ athem atically precise way to an in nite-dim ensionalH rem ains an open problem.

Let $\mathrm{T}\left(\mathrm{t}^{0} ; \mathrm{t}\right)$ be the unitary tim e transform ation which represents Schrodinger tim e evolution from time to tim e $t^{0}$. In the case of a tim e-independent $H$ am iltonian $H$ it is given by:

$$
T\left(t^{0} ; t\right)=\exp \left[\begin{array}{ll}
i\left(t^{0}\right. & t) H=\sim \tag{18}
\end{array}\right]:
$$

The discussion which follow s is not restricted to tim e-independent $H$ am iltonians, but we do require that $T\left(t^{0} ; t\right)$ be unitary and satisfy the conditions

$$
\begin{align*}
\mathrm{T}(\mathrm{t} ; \mathrm{t}) & =\mathrm{I} ; \\
\mathrm{T}\left(\mathrm{t} ; \mathrm{t}^{0}\right) \mathrm{T}\left(t^{0} ; \mathrm{t}^{0}\right) & =\mathrm{T}\left(\mathrm{t} ; \mathrm{t}^{0}\right) ; \tag{19}
\end{align*}
$$

which imply that $T\left(t ; t^{0}\right)$ is the inverse of $T\left(t^{0} ; t\right)$.
G iven $T$ ( $t^{0}$; $t$ ), one can de ne a mapping from an arbitrary operator $\mathbb{A}$ on $H^{n}$ to an operator $K\left(A^{\sim}\right)$ on $H$ by $m$ eans of the formula:
where the $m$ atrix elem ents refer to som e orthonorm albasis $f j \mathrm{j} i g$ of $H$ and the corresponding tensor product basis of $H^{n}$. If, in particular, $\mathbb{A}$ is a pro jector $P^{r}$ of the form (15), then $K$ ( $\mathbb{P}^{\Omega}$ ) takes the form :

$$
\begin{equation*}
K\left(\mathbb{P}^{\sim}\right)=P_{1} T\left(t_{1} ; t_{2}\right) P_{2} T\left(t_{2} ; t_{3}\right) \quad T_{1}\left(t ; t_{n}\right) P_{n}: \tag{21}
\end{equation*}
$$

U sing $K$, we de ne the bilinear consistency functional $C$ on pairs of operators $\mathbb{A}, B$ on $H^{\top}$ by $m$ eans of the form ula:

$$
\begin{equation*}
\left.C\left(\mathbb{A}^{\sim} ; \mathbb{B}^{\check{ }}\right)=C \quad\left(\mathbb{B}^{\Upsilon} ; \mathbb{A}^{\Upsilon}\right)=\operatorname{Tr} \mathbb{K}^{\mathrm{y}}\left(\mathbb{A}^{\Upsilon}\right) \mathrm{K}\left(\mathbb{B}^{\check{ }}\right)\right]: \tag{22}
\end{equation*}
$$

$N$ ote that $C\left(\mathbb{A} ; \mathbb{A}^{\Upsilon}\right)$ is non-negative. If both $\mathbb{A}$ and $B^{\Upsilon}$ are pro jectors of the form (15), the consistency functional is the sam e as the G ell-M ann and H artle decoherence functional if the density $m$ atrix in the latter is replaced by $I$.

Because $\mathrm{H}^{\prime}$ is nite-dim ensional, the Boolean algebra B associated with F contains a nite num ber of projectors, and consequently there are a set of non-zero $m$ inim al elem ents $\mathrm{fM}^{(1)} \mathrm{g},=1 ; 2 ;:::$ which form a decom position of the identity,

$$
\begin{equation*}
I={ }^{X} M^{()} ; M^{()} M^{()}=M^{()} ; \tag{23}
\end{equation*}
$$

in term sof widh any projector $P^{r}$ in $B$ can be written in the form

$$
\begin{equation*}
P^{r}={ }^{X} \mathrm{~m} \mathrm{M}^{(1)} \text {; } \tag{24}
\end{equation*}
$$

$w$ ith each $m$ equalto 0 or 1 , depending on $P$. A n acceptable fram ew ork $F m$ ust satisfy the follow ing consistency condition in term $s$ of these $m$ inim al elem ents:

$$
\begin{equation*}
\mathrm{C}\left(\mathbb{M}^{()} ; \mathbb{M}^{(1)}\right)=0 \text { whenever } \notin: \tag{25}
\end{equation*}
$$

Ifthis is satis ed, a non-negative weightW ( $P^{\curvearrowleft}$ ) can be de ned for every elem ent of $B^{\curvearrowleft}$ through the formula:

$$
\begin{equation*}
\mathrm{W}\left(\mathbb{P}^{\widetilde{\prime}}\right)=\mathrm{C}\left(\mathbb{P}^{\widetilde{5}} ; \mathrm{P}^{\widetilde{J}}\right) ; \tag{26}
\end{equation*}
$$

and these weights can be used to generate conditional probabilities in analogy w th the classical case, [13), and as discussed in (13] and 22]. In particular, with $P^{r}=$ ' (p) and $\sigma={ }^{\prime}(q)$ the projectors associated $w$ ith $p$ and $q$, the counterpart of 13) is the form ula

$$
\begin{equation*}
\operatorname{Pr}(q j p)=W \quad\left(P^{\sim} Q^{\sim}\right)=W \quad\left(P^{\sim}\right) ; \tag{27}
\end{equation*}
$$

w th $W$ de ned by 26).

Ifonly a single tim e is involved, then it is easy to show that the consistency condition (25) is autom atically satis ed. It is also autom atically satis ed for all fam ilies of sim ple histories involving only two tim es, $\mathrm{n}=2$. H ow ever, in the case of generalized histories involving two orm ore tim es, and sim ple histories involving three or m ore tim es, the consistency condition is a non-trivial restriction on acceptable fam ilies.

The consistency functional (22), unlike the decoherence functional of Gell M ann and H artle, does not involve a density $m$ atrix. This $m$ eans that the form er, unlike the latter, does not single out a direction of tim e. There seem sto be no good reason why a density $m$ atrix should appear in a fundam ental form ulation of quantum $m$ echanics, especially since its classical analog is properly part of classical statistical m echanics rather than classical $m$ echanics as such. To be sure, a density $m$ atrix $m$ ay also arise in quantum mechanics, unlike classicalm echanics, as a technical device for describing the state of a subsystem of a total system when the latter is in a pure state. But it is not needed for describing a single closed system, which is what we are considering here. (A lso see the rem arks in Sec.V D.)

## IV D Fram ew orks, C om patibility, and Logical In ference

$T$ he discussion above can be sum $m$ arized by saying that a fram ew ork $F$ for a quantum system at several tim es, usually called a consistent fam ivy of histories, consists of a collection of statem ents generated from a set ofelem entary statem ents by logicaloperations, togetherw ith a m apping ', conform ing in an appropriate way to the logicaloperations, of these statem ents onto a B oolean algebra of com $m$ uting pro jectors on $\mathrm{H}^{\top}$, w ith the additional requirem ent that the $m$ inim al elem ents of this algebra satisfy the consistency condition (25).

A description is then a pair ( F ;f), consisting of the fram ew ork or consistent fam ily $F$ and one of its statem ents $f$. We shall, with a certain lack of precision, call both the description ( $\mathrm{F} ; \mathrm{f}$ ) and the corresponding statem ent f a quantum history. T his ought not to cause confusion ifone rem em bers that statem ents by them selves do not have a m eaning (and, in particular, cannot be true or false) unless they are em bedded in or associated with som e fram ew ork, which can either be speci ed explicitly by giving the pair ( $F$; f), or im plicitly. In particular, if $F^{r}$ is the pro jector corresponding to $f$, then the sm allest Boolean algebra containing $\mathrm{F}^{r}$ de nes, in the absence of any other inform ation, an im plicit fram ew ork for $f$, and this algebra willbe part of the B oolean algebra of any consistent fam ily which has f as one of its statem ents. (N ote that for a particular pro jector $\mathrm{F}^{r}$, even this sm allest Boolean algebra $m$ ay not satisfy the consistency condition (23); in such a case $f$ is an inconsistent (m eaningless) history, which cannot be part of any consistent fam ily.)

The intultive signi cance of a history ( $F$; f) is very sim ilar to that of a description at a single time, as discussed in Sec. $\Psi$. In partioular, in the case of a simple history corresponding to 115), one thinks of the quantum system as actually possessing the property (rep resented by) $P_{j}$ at each tim $e t_{j}$, if this history is the one which actually occurs. $Q$ uantum $m$ echanics, as a stochastic theory, cannot (in general) guarantee that such a history takes place; instead, it assigns it a probability, based on som e assum ption, such as the occurrenœe of the in itial state, using the weights generated by the consistency functional. An em pirical chedk on these probabilities is possible \in principle", ie., by idealized m easurem ents which do not violate the principles of quantum theory; se the extensive discussion in [13].

For a nite collection fF ig of consistent fam ilies to be (m utually) com patible, they m ust,
to begin $w$ ith, refer to a com $m$ on tensor product $H^{r}$, (16), or else it $m$ ust be possible to achieve this by de ning $H^{r}$ using a larger collection of tim es than those found in the individual fam ilies, and then extending the latter by adding identity operators to the histories at the tim es not previously considered. N ext com es a requirem ent of notational consistency: statem ents belonging to the di erent fram ew orks $m$ ust be $m$ apped onto the pro jectors in a consistent way, so that an elem entary statem ent which occurs in $m$ ore than one fram ew ork is $m$ apped to the sam e projector. There are then two additional and speci cally quantum conditions. The rst is the same as in Sec. IIIA: pro jectors corresponding to the di erent B oolean algebras $B_{i}$ of the di erent fam ilies $m$ ust com $m$ ute $w i t h$ each other. The second is the consistency condition (25) im posed on the $m$ inim al elem ents of the Boolean algebra $B^{r}$ associated w ith the sm allest consistent fam ily $F$ containing all the $F_{i}$, the fam ily generated by the collection $\mathrm{fF}_{\mathrm{i}} \mathrm{g}$.

G iven these de nitions, one has the sam e fundam ental rule as in Sec. IIIB; worded in term sofhistories, it reads: A m eaningfulquantum history $m$ ust consist of a single consistent fam ily together with one of its histories (statem ents), ( F ; f), or else a com patible collection of consistent fam ilies $f F_{i} g$ and associated histories $\mathrm{ff}_{\mathrm{i}} \mathrm{g}$, which together form a collective history (or description) $f\left(F_{i} ; f_{i}\right) g$. A collective history can alw ays be replaced by a single $m$ aster history ( $\mathrm{D} ; \mathrm{d}$ ), where D is the consistent fam ily generated by the collection $\mathrm{fF}{ }_{i} \mathrm{~g}$, and d is any history corresponding to the projector $\widetilde{V}^{\sim}$ which is the product of the projectors $\mathrm{F}_{\mathrm{i}}$ corresponding to the histories $f_{i}$, as in (9).

The rules for logical reasoning in the case of histories are sim ilar to those for a quantum system at one tim e, Sec. IIB, except that they are based upon conditionalprobabilities constructed from ratios of weights, using 27). A n argum ent begins with a a set of assum ptions, which is to say a set of histories or descriptions $f\left(A_{i} ; a_{i}\right) g ; i=1 ; 2 ;::: l$, associated $w$ ith a com patible set $f A_{i} g$ of consistent fam ilies; one is assum ing that these histories are sim ultaneously true (w ithin the consistent fam ily generated by the collection $f A_{i} g$ ). From these one can deduce a set of valid conclusions $f\left(C_{j} ; C_{j}\right) g ; j=1 ; 2 ;::: m$, provided the union of the collections $\mathrm{fA}_{\mathrm{i}} 9$ and $\mathrm{fC}_{\mathrm{j}} \mathrm{g}$ is a com patible collection of consistent fam ilies, and provided

$$
\begin{equation*}
\operatorname{Pr}\left(C_{j} j A^{\sim}\right)=W \quad\left(C_{j} A^{\sim}\right)=W \quad\left(\mathbb{A}^{\sim}\right)=1 \tag{28}
\end{equation*}
$$

holds for every $j$, where $C_{j}={ }^{\prime}\left(c_{j}\right)$, and

$$
\begin{equation*}
\overparen{A}=\overparen{A}_{1} \mathbb{A}_{2} \quad \overparen{A}_{1} ; \tag{29}
\end{equation*}
$$

$w$ ith $A_{i}$ the pro jector associated w ith the history $a_{i}$. In order for the inference to be valid, we require that $W$ ( $A^{\sim}$ ) be positive, so the right side of (28) is de ned. The case $W$ ( $A^{\top}$ ) = 0 corresponds to a probability of zero that all of the assum ptions in the argum ent are sim ultaneously satis ed, and is thus sim ilar to having contradictory hypotheses in ordinary logic. Excluding the possibility of $m$ aking any inferences from probability zero cases, as suggested here, seem s intrinsically no w orse than the solution in ordinary logic, in which any statem ent whatsoever can be inferred from a contradiction.

These rules coincide w ith those given in Sec. IIIB in the particular case where $\mathrm{n}=1$, assum ing $H$ is nite dim ensional, because $W(P)$ for a projector $P$ is then just the dim ension of the space onto which $P$ projects. The case of contradictory assum ptions, $A=0$, again form $s$ an exception, for the reasons discussed above.

The rem arks at the end of Sec. III B about the necessity of choosing a particular fram ework in order to describe a quantum system also apply to a quantum history. It is necessary to choose som e consistent fam ily, if only im plicitly, in order to describe the tim e develop$m$ ent of a quantum system, and while this choige has no in uence upon the system itself, it constrains w hat can sensibly be said about it. T he consistent fam ily is not itself either tnue or false, but a history can be tnue or false, ie., occur or not occur, as one of the possibilities w ithin a consistent fam ily. A s long as one considers a single fam ily, a particular history may well exclude another history in the sense that the probability is zero that both occur. But this sort of exclusion is very di erent from that which arises when two histories $f$ and $g$ are incom patible in the sense that there is no consistent fam ily whidh includes both of them. In such a case, the occurrence of history $f$ does not imply that $g$ does not occur; what it $m$ eans is that in order to even talk about the occurrence of $f$, we m ust em ploy a fram ew ork or consistent fam ily in which it $m$ akes no sense to say whether or not $g$ occurs, since $g$ is not one of the histories in this fam ily, and could not be added to this fam ily $w$ ithout $m$ aking it inconsistent. For the sam e reason, statem ents such as \f and g", or \f or $\mathrm{g}^{\prime \prime}$, m ake no sense when these histories cannot both belong to a single consistent fam ily. Such com binations are like im properly-form ed form ulas in $m$ athem atical logic, sequences of sym bols whidh cannot be interpreted because they are not constructed according to the rules appropriate to the particular language under discussion.

## V Applications

## V A M easurem ents

A s a sim ple exam ple of a m easurem ent, consider the process of determ ining $S_{x}$, the $x$ com ponent ofspin, for a spin $1 / 2$ particle using a Stem-G erlach apparatus equipped w ith detectors to determ ine in which channelthe particle em erges from the region where there is a m agnetic
eld gradient. T he essential features of the unitary tim e transform ation $T\left(t_{2} ; t_{1}\right)$ from a time $t_{1}$ before the $m$ easurem ent takes place to a time $t_{2}$ after it is completed are, in an obvious notation:

$$
\begin{equation*}
\text { j;Xi! j }{ }^{0} ; X^{+} i ; ~ j ; X i!~ j{ }^{0} \text {; X i; } \tag{30}
\end{equation*}
$$

where ji corresponds to the spin state $S_{x}=1=2$ for the particle, in units of $\sim$, $j$ ito $S_{x}=1=2$, $X$ i to the \ready" state of the apparatus before the particle has arrived, and $\mathrm{K}^{+}$i and $\mathrm{K}_{\mathrm{X}} \mathrm{i}$ are apparatus states $w$ hich result if the particle em erges from the eld gradient in the $S_{x}=1=2$ or $S_{x}=1=2$ channel, respectively. O ne should think of $X^{+} i$ and j i as m acroscopically distinct states corresponding to, say, tw o distinct positions of a pointer which indicate the outcom e of the measurem ent. The spin states $j{ }^{0} i$ and $j{ }^{0} i$ at tim e $t_{2}$ are arbitrary; they are not relevant for the $m$ easuring process we are interested in. Throughout the follow ing discussion we em ploy a sym bol outside a D irac ket to indicate the corresponding projector; for exam ple:

$$
\begin{equation*}
=j i h j X^{+}=j X^{+} i h X^{+} j: \tag{31}
\end{equation*}
$$

As a rst fram ew ork or consistent fam ily $\mathrm{F}_{1}$, we use the one generated by , and X at $t_{1}$, and $X^{+}$and $X$ at $t_{2}$. To use the term inology of Sec $I V, F_{1}$ contains statem ents
of the type $p: \backslash S_{x}=1=2$ at time $t_{1} ", q$ : \the pointer at $t_{2}$ corresponds to the apparatus having detected the particle em erging in the $S_{x}=1=2$ channel", and the like, which are then m apped to projectors

$$
\begin{equation*}
{ }^{\prime}(\mathrm{p})=\quad \mathrm{I} \boldsymbol{j}^{\prime}(\mathrm{q})=\mathrm{I} \quad \mathrm{X}^{+} \text {; } \tag{32}
\end{equation*}
$$

etc., on $H^{2}$. The result is a B oolean algebra of projectors associated w ith a fam ily of sim ple histories at only two tim es, which is therefore autom atically consistent.
$G$ iven the fram ew ork $F_{1}$, it is possible to use the weights (26) generated by the consistency functional, see [13, 22], to calculate various conditional probabilities such as:

$$
\begin{equation*}
\operatorname{Pr}\left(; t_{1} j X^{+} ; t_{2}\right)=1 ; \operatorname{Pr}\left(; t_{1} j X^{+} ; t_{2}\right)=0: \tag{33}
\end{equation*}
$$

Stated in words, given that the apparatus is in state $X^{+}$at $t_{2}$, one can be sure that the particle was in the spin state $S_{x}=1=2$ and not $S_{x}=1=2$ at time $t_{1}$. This is certainly the sort of result which one would expect to em erge from a reasonable quantum theory of $m$ easurem ent, and which does, indeed, em erge if one chooses an appropriate fram ew ork.

N ext, consider a situation in which for som e reason one know s that the particle at tim e $t_{1}$ has a spin polarization $S_{z}=1=2$ corresponding to the spin state

$$
\begin{equation*}
j i=(j i+j i)={ }^{p} \overline{2} \text {; } \tag{34}
\end{equation*}
$$

for exam ple, the particle $m$ ay have com e through a spin polarizer which selected this polarization. W hat will happen during the m easurem ent process? W e adopt as a fram ew ork the consistent fam ily $\mathrm{F}_{2}$ which is generated by $\quad\left(\mathrm{S}_{\mathrm{z}}=1=2\right)$,

$$
\begin{equation*}
j i=(j i \quad j i)={ }^{p} \overline{2} \tag{35}
\end{equation*}
$$

$\left(S_{z}=1=2\right)$, and $X$ at $t_{1}$; and, as before, $X^{+}$and $X$ at $t_{2} . U$ sing this fram ew ork (again, consistency is autom atic) and the weights generated by the consistency functional, one can calculate probabilities such as:

$$
\begin{equation*}
\operatorname{Pr}\left(X^{+} ; t_{2} j ; X ; t_{1}\right)=\operatorname{Pr}\left(X \quad ; t_{2} j ; X ; t_{1}\right)=1=2: \tag{36}
\end{equation*}
$$

Stated in words, given that $S_{z}=1=2$ and the apparatus $w$ as ready at $t_{1}$, the probability is $1 / 2$ that the apparatus is in the $\mathrm{X}^{+}$state, and $1 / 2$ that it is in the X state at time $\mathrm{t}_{2}$.

A lldiscussions w ithin the fram ew ork of standard quantum $m$ echanics eventually arrive at the conclusion (36), but $m$ any of them are forced to $m$ ake equivocations and unsatisfactory excuses along the way. The reason is that they adopt (im plicitly) yet another fram ew onk, $\mathrm{F}_{3}$, which is generated by and at $\mathrm{t}_{1}$, and at $\mathrm{t}_{2}$ the state

$$
\begin{equation*}
j G i=T\left(t_{2} ; t_{1}\right) j ; X i=\left(j^{0} ; X^{+} i+j^{0} ; X \quad i\right)={ }^{p} \overline{2}: \tag{37}
\end{equation*}
$$

w ith pro jector $G$. To be sure, $\mathrm{F}_{3}$ is an acceptable fram ew ork, the consistency conditions are satis ed, and w ithin this fram ew ork one can derive the conditional probability

$$
\begin{equation*}
\operatorname{Pr}\left(G ; t_{2} j ; X ; t_{1}\right)=1: \tag{38}
\end{equation*}
$$

Stated in words, it is the case that if one uses the consistent fam iry $\mathrm{F}_{3}$, the state G w ill occur w ith certainty at $t_{2}$, given that $S_{z}=1=2$ and the apparatus was ready at $t_{1}$.

The problem, of course, is that $\bar{j} \mathcal{G} i$ is a macroscopic quantum supenposition $(M Q S)$, or Schrodinger's cat state, and tells one nothing whatsoever about the position of the pointer on the apparatus. Indeed, adopting $F_{3} m$ akes it im possible even to discuss whether the apparatus is in state $X^{+}$or $X$ at the end of the $m$ easuring process, because the pro jectors $\mathrm{X}^{+}$and X do not com mute w ith G. All attem pts to som ehow deduce that the pointer is in one position or the other \for all practical purposes" are nonsensical once fram ew ork $\mathrm{F}_{3}$ has been adopted, in agreem ent w ith B ell's observations 24], based upon m ore intuitive, but nonetheless quite reasonable argum ents. If one wants to talk about the pointer positions, it is necessary to adopt a fram ew ork which includes the possibility of $m$ aking references to such positions, for exam ple, $\mathrm{F}_{2}$. But note that $w$ thin $\mathrm{F}_{2}$ 进 is equally nonsensical to refer to the MQS state G. Thus one sees that the enorm ous confiusion which surrounds $m$ ost discussions of \the $m$ easurem ent problem " is generated by a failure to distinguish the di erent fram ew orks or consistent fam ilies which are possible in quantum theory, and to note that a description em ploying one fram ew ork necessarily exchudes certain statem ents valid in other, incom patible fram ew orks.

The consistent fam ily $\mathrm{F}_{2}$, while it evades the problem of \ghostly" M Q S states, can be faulted as a description of a $m$ easurem ent process in that the outcom $e$ of the m easurem ent in term $s$ of pointer positions is not correlated w ith a property of the particle before the $m$ easurem ent. This can be rem edied by em bedding $F_{2}$ in a larger fram ew ork $F_{4}$ which is generated by the events already included in $F_{2}$ at $t_{1}$ and $t_{2}$, and, in addition, and , $S_{x}=1=2$, at a tim e $t_{1: 5}$ which is later than $t_{1}$ but earlier than the instant $w$ hen the particle actually enters them agnetic eld gradient of the apparatus. It tums out that $\mathrm{F}_{4}$ is consistent (this m ust be checked, as it is no longer autom atic), and using it one can show, am ong other things, that

$$
\begin{equation*}
\operatorname{Pr}\left(; t_{1: 5} j ; X ; t_{1} ; X^{+} ; t_{2}\right)=1 ; \tag{39}
\end{equation*}
$$

i.e., given the initial state at $t_{1}$, and the fact that $a t_{2}$ the pointer indicates that the particle has em erged in the $S_{x}=1=2$ channel, it follow $s$ that the spin state was $S_{x}=1=2$ at the tim e $t_{1: 5}$. T hus, using this fram ew ork, one can again say that the apparatus after them easurem ent indicates a state possessed by the particle before the $m$ easurem ent. There is, incidentally, nothing incom patible between having $S_{z}=1=2$ at $t_{1}$ and $S_{x}=1=2$ at $t_{1: 5}$ for the same particle, since these statem ents belong to the sam e fram ew ork or consistent fam ily. This is just one of the ways in which consistent quantum reasoning, with its precise nules, allows one to go wellbeyond what is possible in standard quantum m echanics slavishly interpreted in term $s$ of ill-de ned $\backslash m$ easurem ents".
$T$ his set of exam ples show $s$ that a satisfactory theory of quantum $m$ easurem ent requires the use of a fram ew ork which includes the possibility of discussing both the outcom e shown by the apparatus and, at a tim e before the m easurem ent, the properties of the m easured system which the $m$ easurem ent is designed to detect. To be sure, precisely the sam e conditions apply to a satisfactory theory ofm easurem ent in the context of classicalm edhanics. $T$ he di erence is that in the classical case the choice of an appropriate fram ew ork can be $m$ ade im plicitly w ith no di culty, whereas in the quantum case it is necessary to choose it $w$ ith som e care, in order to avoid $m$ eaningless statem ents associated $w$ ith attem pts to $m$ ix descriptions belonging to incom patible fram ew orks.

## V B Spin of a Particle B etw een Two M easurem ents

The follow ing exam ple, w ith trivialdi erences in notation, is from 133; applying the rules for descriptions contained in the present paper clari es the original presentation and responds to certain criticism s 19, 25].

C onsider a spin 1/2 particle which passes through tw o successive devices which m easure the spin polarization, $F$ ig.1. The rst device $m$ easures $S_{x}$ w ithout changing it, so the unitary transform ation is

$$
\begin{equation*}
\text { j;X i! j; } \mathrm{X}^{+} \text {i; j;Xi! j;X i; } \tag{40}
\end{equation*}
$$

which is identical to (30) except that the spin states $\left(\mathrm{S}_{\mathrm{x}}=1=2\right)$ and ( $\mathrm{S}_{\mathrm{x}}=1=2$ ) are the sam e before and after the $m$ easurem ent. A s in Sec.V A, XX i is the \ready" state of the device, and $\mathrm{X}^{+}$i and X i correspond to the two di erent pointer positions indicating the results of the $m$ easurem ent. T he second device, $F$ ig. 1 , is sim ilar, except that it m easures $S_{z}$, $w$ ith states zi ( $\backslash$ ready"), and $\mathrm{z}^{+} i$ and z i corresponding to having $m$ easured $S_{z}=1=2$ and $S_{z}=1=2$, respectively.

A s indicated in Fig. 1 , let $t_{1}$ be som e tim e before the particle enters the rst device, when its spin state is $j i$, corresponding to $S_{z}=1=2 ; t_{2}$ a timewhen it is between the two devioes; and $t_{3}$ a time when the particle has left the second devioe, and the pointers on both devices indicate the results of the respective $m$ easurem ents. Suppose that at $t_{3}$ the $m$ easuring devioes are in states $\mathrm{X}^{+} i$ and $z^{+} i$. W hat can one conclude about the spin of the particle at the tim e $t_{2}$ when it was betw een the two deviges?

F irst consider a consistent fam ily $\mathrm{F}_{1}$ generated by the initial state

$$
\begin{equation*}
j_{1} i=j X Z i \tag{41}
\end{equation*}
$$

at $t_{1}$ together $w$ ith the pointer positions for both devioes at $t_{3}$. $C$ onsistency is autom atic, as sim ple histories at only two tim es are involved. U sing this fam ily, one can calculate the conditional probabilities for the nal pointer positions given the intitial state; for exam ple,

$$
\begin{equation*}
\operatorname{Pr}\left(X^{+} Z^{+} ; t_{3} j_{1} ; t_{1}\right)=1=4: \tag{42}
\end{equation*}
$$

$N$ ext consider the fam ily $F_{2}$ obtained from $F_{1}$ by adding $S_{x}$ at time $t_{2}$. This fam ily is consistent, and using the corresponding weights one can show that

$$
\begin{equation*}
\operatorname{Pr}\left(S_{x}=1=2 ; t_{2} j_{1} ; t_{1} ; X^{+} Z^{+} ; t_{3}\right)=1 ; \tag{43}
\end{equation*}
$$

for the detailed caloulation, see [13]. That is, given the initial state and the nal pointer positions, one can be certain that at the interm ediate tim e $t_{2}$ the particle was in a spin state $S_{x}=1=2$. $N$ ote that this inference can be checked, in principle, by inserting a third devige betw een the rst tw o , show n dashed in F ig. 1 , which $m$ easures $S_{x}$, and verifying that it yields the sam e result as the rst device.
$O$ ne can also consider the fam ily $F_{3}$ obtained from $F_{1}$ by adding $S_{z}$ at time $t_{2}$. This, too, is consistent, and w ith the help of the corresponding weights (again, details are in [13]) one can show that

$$
\begin{equation*}
\operatorname{Pr}\left(S_{z}=1=2 ; t_{2} j_{1} ; t_{1} ; X^{+} Z^{+} ; t_{3}\right)=1: \tag{44}
\end{equation*}
$$

That is, given the same conditions as in (43) one can conclude that at the time $t_{2}$ the particle was in a spin state $S_{z}=1=2$. This inference is not particularly surprising when one
rem embers that, as shown in Sec. VA, the outcom e of a m easurem ent allow s one to infer the state of the $m$ easured system prior to the tim e when the m easurem ent takes place, if one uses an appropriate consistent fam ily.

N ote that there is no inconsistency betw een 43) and 44), because the conclusion $S_{x}=$ $1=2$ holds $w$ thin fram ew ork $F_{2}$, and $S_{z}=1=2 \mathrm{w}$ ithin fram ew ork $\mathrm{F}_{3}$, and these two fram ew orks are incom patible w ith each other, even though each one separately is com patible w ith $F_{1}$. T hus we have an exam ple of the possibility noted in Sec. IIIB, of tw o logical argum ents based upon the sam e assum ption, but using incom patible fram ew orks, and whose conclusions cannot, therefore, be com bined.

The correctness of $S_{z}=1=2$, w thin the fram ew ork $\mathrm{F}_{3}$, can be veri ed, in principle, by inserting a third device betw een the rst two, Fig. 1, but this tim e of a type which m easures $S_{z}$, and verifying that it yields the sam e result as the naldevige the particle passes through. O nem ay w orry that this third devige som ehow \creates" a value of $S_{z}$ which was \not there" before the particle passed through it. Such a worry is best put to rest by m eans of a precise analysis, and the reader is invited to carry out the appropriate calculations using a fram ew ork $F_{4}$ in which, w ith all three devices present, $S_{z}$ is speci ed both at $t_{2}$ and at a tim e $t_{2: 5}$ when the particle is betw een the two deviges which m easure $S_{z}$. It is easily show $n$ that $S_{z}$ has the sam e value at both these tim es; thus, passing through the interm ediate devige does not alter this com ponent of the spin.

## V C D ouble S lit

A com plete discussion of the paradoxes associated w ith double-slit di raction 26] would require, at the very least, a theory ofquantum counterfactuals, and that is beyond the scope of the present article. A signi cant insight into the source of the conceptual di culties can, nonetheless, be obtained using the tools of Secs. III and $\mathbb{I V}$. In order to focus on the essentials, we shall use the idealization that at time $t_{1}$ the particle is described by a wavepacket ${ }_{1}(r)$ which is approaching the slits from the left in the geom etry of $F$ ig. 2 , and that at a later tim e $t_{2}$ the w ave padket resulting from ${ }_{1}(r)$ by unitary tim e evolution consists of three pieces, two of which are waves con ned to the regions $R_{A}$ and $R_{B}$ just behind the two slits and m oving to the right, and the third a re ected wave located to the left of, and traveling aw ay from the slits. A nd we shall regard the presence, at tim e $t_{2}$, of the particle in $R_{A}$, represented by a pro jector $P_{A}$, as equivalent to the statem ent that the particle passed through slit A", and likew ise its presence in $R_{B}$, projector $P_{B}$, as equivalent to its having passed through slit $B$. In addition, let the pro jector $P=P_{A}+P_{B}$ correspond to the region

$$
\begin{equation*}
\mathrm{R}=\mathrm{R}_{\mathrm{A}}\left[\mathrm{R}_{\mathrm{B}}:\right. \tag{45}
\end{equation*}
$$

(T he projector $P_{A}$ acting on a wave function ( $r$ ) produces a function $\sim(r)$ equal to ( $r$ ) for r inside $R_{A}$, and equal to 0 for r outside $R_{A} ; P_{B}$ is de ned in a sim ilar way.) By time $t_{3}$ the particle, if it has passed through the slit system at all, will have been detected by one of the detectors in the di raction region, shown as circles in $F i g .2$, where for convenience the distance betw een the detectors and the slits has been considerably shortened.

A ll the fram ew orks or consistent fam ilies in the discussion which follow s w ill include an initial state

$$
\begin{equation*}
j_{1} i=j_{1} ; D_{1} ; D_{2} ;::: D_{m} i \tag{46}
\end{equation*}
$$

at time $t_{1}$, where $D_{j}$ indicates that detector $j$ is ready to detect a particle. $T$ he rst fam ily $\mathrm{F}_{1}$ wew ish to consider has, in addition to the initialstate, projectors $\mathrm{D}_{1} ; \mathrm{D}_{2} ;:::$ at $\mathrm{t}_{3}$, where $D_{j}$ is a pro jector indicating that detector $j$ has detected a particle. Since $F_{1}$ involves sim ple histories at just two tim es, the consistency condition is satis ed, and the weights 26) m ay be used to calculate the probability

$$
\begin{equation*}
\operatorname{Pr}\left(D_{j} ; t_{3} j{ }_{1} ; t_{1}\right) \tag{47}
\end{equation*}
$$

that, given the initial conditions, the joth counter will trigger. Its dependence on $j \mathrm{w}$ ill exhibit the usual di raction pattem.

The next fam ily of interest, $\mathrm{F}_{2}$, is obtained by adding to the events of $\mathrm{F}_{1}$ an event corresponding to the particle being in the region $R$ 45), projector $P$, at tim $e t_{2}$. $T$ his is again a consistent fam ily in which one can calculate quantities such as

$$
\begin{equation*}
\operatorname{Pr}\left(P ; t_{2} j \quad ; t_{1}\right) \tag{48}
\end{equation*}
$$

the probability that the particle was not re ected by the slit system, and

$$
\begin{equation*}
\operatorname{Pr}\left(D_{j} ; t_{3} j P ; t_{2} ; 1 ; t_{1}\right) ; \tag{49}
\end{equation*}
$$

the probability that the joth counter w ill trigger if the particle passes through the slit system . The latter shows the same di raction pattem as 47), as a function of j, aside from a $m$ ultiplicative constant. On the other hand, attem pting to add to $F_{2}$ the events that the particle is in one of the regions $R_{A}$ or $R_{B}$ at $t_{2}$ results in an inconsistent fam ily, despite the fact that the corresponding pro jectors $P_{A}$ and $P_{B}$ can be included in a B oolean algebra of projectors for the tensor product $H^{3}$. Thus, while one can consistently say that the particle was in R " at time $t_{2}$, it makes no sense, given this fram ew ork, to say that the particle was in $R_{A}$, or it was in $R_{B}$ ". But given that $R$, (45), is the union of two disjoint regions $R_{A}$ and $R_{B}$, it is di cult not to interpret the second phrase as equivalent to the rst. Thus we have a situation where it $m$ ay actually be helpful, in order to avoid confusion, to em ploy the pro jectors them selves in place of the corresponding English phrases.

The preceding discussion show s that the consistent history analysis supports the usual intuition that it is som ehow im proper to talk about which slit the particle passed through. H ow ever, it replaces an intuition which is alw ays a little vague w ith a precise $m$ athem atical criterion based upon the $H$ ibert space stnucture ofquantum $m$ echanics. $T$ hat this represents a signi cant advance is evident when one com es upon circum stances, such as that in which a detector is placed directly behind one of the slits, in which it seem s intuitively plausible that one should be able to specify the slit through which the particle passed.

Even w ithout displacing the detectors, one can construct a fram ew ork which perm its one to say which slit the particle passed through, once again for convenience interpreting this as an assertion about its presence in $R_{A}$ or $R_{B}$ at $t_{2}$. Let $F_{3}$ be the fam ily generated by $P_{A}$ and $P_{B}$ at $t_{2}$ along w ith 1 at $t_{1}$, and (for the $m$ om ent) no events at $t_{3}$. As these sim ple histories involve only two tim es, consistency is autom atic. O ne can then calculate the probabilities

$$
\begin{equation*}
\operatorname{Pr}\left(\mathrm{P}_{\mathrm{A}} ; \mathrm{t}_{2} j 1 ; \mathrm{t}_{1}\right) ; \operatorname{Pr}\left(\mathrm{P}_{\mathrm{B}} ; \mathrm{t}_{2} j 1 ; \mathrm{t}_{1}\right) ; \tag{50}
\end{equation*}
$$

that the particle passed through slit A and slit B , respectively, and dem onstrate that the particle surely did not pass through both slits by using the fact that $\mathrm{P}_{\mathrm{A}} \mathrm{P}_{\mathrm{B}}=$; . If, how ever,
one attem pts to add to $\mathrm{F}_{3}$ events of the sort $\mathrm{D}_{j}$ at $\mathrm{t}_{3}$, the result is an inconsistent fam ily. From this we see that what prevents one from sensibly talking about which slit the particle passes through in the usual discussions of double slit di raction is directly tied to the (m plicit) requirem ent of being able to describe the point at which the particle will arrive, or be detected, in the di raction plane. A description which includes which slit the particle goes through can also consistently include events referring to the detectors at tim e $t_{3}$; these events m ust, how ever, be suitable M Q S states. This suggests that the absence of a precise, clear discussion of two-slit di raction in textbooks is not unrelated to the absence of a clear treatm ent of M Q S states and the m easurem ent problem. A consistent logical analysis using the concept of a fram ew ork is able to dispose ofboth problem s sim ultaneously.

## V D Em ergence of the C lassical W orld

Both G ellM ann and Hartle [15], and Om nes [14] have discussed, from slightly di erent perspectives, how classical physics expressed in term s of suitable \hydrodynam ic" variables em erges as an approxim ation to a fully quantum $m$ echanical description of the world when the latter is carried out using suitable fram ew orks, i.e., fam ilies of consistent histories. It is not our puppose to recapitulate or even sum $m$ arize their detailed technical discussions, but instead to indicate the overall strategy, as view ed from the perspective of this paper, and how it is related to processes of \decoherence" 28] which arise when a particular quantum subsystem of interest interacts w ith a suitable environm ent, both of which are part of a larger (closed) quantum system.

The basic strategy of ellH M ann and H artle can be thought of as the search for a suitable \quasi-classical" fram ew ork, a consistent fam ily whose B oolean algebra includes pro jectors appropriate for representing coarse-grained variables, such as average density and average m om entum inside volum e elem ents which are not too sm all, variables which can plausibly be thought of as the quantum counterparts of properties which enter into hydrodynam ic and other descriptions of the w orld provided by classical physics. H ence it is necessary rst to nd suitable commuting projectors, and then to show that the consistency conditions are satis ed for the corresponding B oolean algebra. O m nes states his strategy in som ew hat di erent term swhich, how ever, seem at least roughly com patible w ith the point of view just expressed. ( T he actual technical calculations of Gell M ann and H artle, and of O m nes are based on sim ple, rather than generalized histories, in the term inology of Sec. IV B..)

O ne $m$ ight worry that the strategies of $O m$ nes, and GellM ann and $H$ artle, are incom patible w ith the formulation of quantum theory contained in the present paper, because their consistency conditions em ploy a density m atrix, whereas that in Sec. IV C does not. H ow ever, the di erence is probably of no great im portance when discussing \quasi-classical" system $s$ involving large num bers of particles, for the follow ing reason. In classical statisticalm echanics one knows (or at least believes!) that for $m$ acroscopic system $s$ the choioe of ensemble| $m$ icrocanonical, canonical, or grand |is form any punposes unim portant, and, indeed, the average behavior of the ensem ble will.be quite close to that of a \typical" m em ber. Stated in other words, the use of probability distributions is a convenience which is not \in principle" necessary. P resum ably an analogous result holds for quantum system s of m acrosoopic size: the use of a density matrix, both as an \initial condition" and as part of the consistency requirem ent $m$ ay be convenient, but it is not necessary when one is discussing
the behavior of a closed system. O fcourse, there are issues here which deserve serious study; the proper form ulation of tim e-dependent phenom ena in quantum statistical mechanics is an open problem, Sec.VIB.

The task of nding an appropriate quasi-classical consistent fam ily is $m$ ade som ew hat easier by two facts. The rst is that decoherence (as de ned above) is quite e ective in reducing \o -diagonal" term $\mathrm{SC}\left(\mathrm{M}^{(1)} ; \mathrm{M}^{(1)}\right)$, with $G$, in the consistency functional (42) for a suitably chosen B oolean algebra representing quasi-classical variables in circum stances in which them odynam ic irreversibility plays a role. T he second is that the consistency functional is a continuous function of its argum ents, and hence it is plausible that by making sm all changes in the projectors form ing the B oolean algebra, one can reduce the o -diagonal elem ents to zero, assum ing they are already sm all (see D ow ker and K ent 19]) so that the consistency condition (25) is satis ed. Since there is in any case som e arbitrariness in choosing which quantum projectors to associate w ith particular coarse-grained hydrodynam ic variables, sm all changes in these projectors are unim portant in term $s$ of their physical interpretation. Thus exact consistency does not seem di cult to achieve \in principle", even if in practige theoreticalphysicists are unlikely to be w orried if the \o -diagonal" elem ents of the consistency functional are not precisely zero, as long as they are suitably sm all in com parison w ith the \diagonal" weights C ( $\mathrm{P}^{\sim} ; \mathrm{P}^{\sim}$ ) which enter into a calculation of probabilities.

There are $m$ any fram ew orks which are not quasicclassical, and from a fundam entalpoint of view there is no reason to exclude using one of these to describe the world. The fundam ental principles of quantum $m$ echanics no $m$ ore dictate the choige of a fram ew ork than the concepts of geom etry dictate which projection a draftsm an must use for representing a three-dim ensional object. In both cases the issues are practical ones, related to what one is trying to achieve. A s noted in SecVA, a fram ew ork which includes M Q S states of a $m$ easurem ent apparatus after the $m$ easurem ent prechudes any attem pt to think of the process of its interaction $w$ ith the $m$ easured system as a $\backslash m$ easurem ent" in the ordinary sense of that word. U sing M Q S states to describe Schrodinger's cat does nothing whatsoever to the cat, but it does $m$ ake it im possible to discuss whether the cat is or is not alive, for such a discussion will em ploy concepts of a quasi-classical kind which cannot be inchuded in the
 w orld of everyday experience or of experim entalphysics m ust em ploy som e fram ew ork which allow s a description of the appropriate kind.

As a nal rem ark, the fact that in Sec. VA above no m ention was m ade of decoherence in addressing the $\backslash \mathrm{m}$ easurem ent problem " should not be taken to m ean that considerations of decoherence are irrelevant to discussions of quantum m easurem ents; quite the opposite is the case. For exam ple, the fact that certain physical properties, such as pointer positions in a properly designed apparatus, have a certain stability in the course of tim e despite perturbations from a random environm ent, while other physicalproperties do not, is a m atter of both theoretical and practical interest. H ow ever, decoherence by itself cannot single out a particular fram ew ork of consistent histories, nor can it disentangle conceptual dilem $m$ as brought about by $m$ ixing descriptions from incom patible fram ew orks. To the extent that the latter form the heart of the \m easurem ent problem ", decoherence will not resolve it, and claim $s$ to the contrary $m$ erely add to the confusion.

## V I Sum m ary and Open $Q$ uestions

## V I A Sum m ary

The description of a quantum system and the reasoning process relating one description to another are best thought of in term s of a fram ew ork, which serves to establish, in e ect, a topic of conversation or a point of view, and statem ents, which are assertions about the state of a quantum $m$ echanical system which are either true or false $w$ thin the fram ew ork w ith which they are associated. A classical analogy, Sec. II A, in which a fram ew ork must be chosen by the person constructing the description, and truth is relative to this fram ework, suggests that there is no reason to treat quantum descriptions as less \ob jective" than their classical counterparts. The m ost im portant di erence betw een classical and quantum descriptions is the fact that in the quantum case there are incom patible fram ew orks, any one of which could be em ployed for constructing descriptions of a given system, but which cannot be combined, either for the process of describing the system or reasoning about it. This incom patibility has no direct classical analog, and it leads to the rule which states that any description of a quantum system must either em ploy a single fram ew ork or a com patible fam ily of fram ew orks. Sím ilarly, a logical argum ent, leading from certain descriptions, taken as assum ptions, to other descriptions which form the conclusions, m ust use a single fram ework or a com patible fam ily of fram ew orks. In the case of a classicalm echanical system, a single fram ew ork su ces for all descriptions, and this fram ew ork is often chosen im plicitly. A quantum fram ew ork can also be chosen im plicitly, but carelessness can lead to invalid reasoning and to paradoxes.

The sam e com bination of fram ew ork and statem ent can be used to describe the behavior of a quantum system as a function of time. In this case the fram ew ork is usually called a \consistent fam ily of histories". O nœe again, a valid description or history m ust be based upon a single fram ew ork or consistent fam ily, or a com patible set of consistent fam ilies, and a logical argum ent leading from assum ptions to conclusions m ust likew ise em ploy a single consistent fam ily or a com patible set of fam ilies. It is convenient to represent (generalized) histories involving $n$ tim es using projectors on the tensor product of $n$ copies of the $H$ ibert space. The consistency condition can then be expressed using a bilinear consistency functional of such projectors, and when consistency is satis ed, the weights which determ ine conditional probabilities can also be com puted using this consistency functional.

A pplications of the form alism just described inchude $m$ easuring processes, the state of a quantum system betw een $m$ easurem ents, double-slit di raction, and the em ergence of the classical world from a fully quantum mechanical theory.

## VIB Open Questions

The discussion of consistency in Sec. IV C was carried out assum ing a nite-dim ensional H ilbert space in order to ensure, am ong other things, that the trace (22) and the $m$ inim al elem ents (23) of the Boolean algebra B" exist. It seem $s$ likely that by $m$ aking suitable restrictions on $\mathrm{B}^{2}$, the concept of consistency can be extended in a satisfactory way to an in nite-dim ensional H ilbert space, but this needs to be worked out in detail. There are sim ilar technical issues associated with fram ew orks which em ploy an in nite collection of
elem entary statem ents, the com patibility of in nite collections of fram ew orks, and histories de ned at an in nite set of tim es.

The structure for quantum reasoning proposed in this paper includes no mechanism for dealing w ith counterfactuals ( $\backslash$ if the counter had not been located directly behind the slit, then the particle would have :: :"). Inasmuch as many quantum paradoxes, including som e of the ones associated w th double-slit di raction, and certain derivations of Bell's inequality and analogous results, $m$ ake use of counterfactuals, disentangling them requires an analysis which goes beyond what is found in the present paper. A s philosophers have yet to reach general agreem ent on a satisfactory schem e for counterfactual reasoning applied to the classical world [27], an extension which covers all of quantum reasoning is likely to be di cult. On the other hand, a schem e su cient to handle the special sorts of counterfactual reasoning found in com $m$ on quantum paradoxes probably represents a sim pler problem.

The proper form ulation of tim e-dependent phenom ena in quantum statisticalm echanics rem ains an open question. On the one hand, as noted in Sec. V D, it seem s plausible that various form ulas which yield the \average" behavior of som em acroscopic system are not in need of revision, since, am ong other things, this \average" is likely to be essentially the sam e as the behavior of a typicalm em ber of an ensemble, and because decoherence (interaction w ith the environm ent) is very e ective in rem oving violations of the consistency conditions if one chooses an appropriate \quasi-classical" consistent fam ily. The results obtained in [14, 15] are quite encouraging in this connection. On the other hand, thought needs to be given to those cases in which di erent $m$ em bers of an ensem ble have signi cantly di erent behavior, that is, where \uctuations" are im portant. In any event, it would be useful to have a restatem ent of the fundam ental principles of quantum statistical m echanics based upon a fully consistent interpretation of standard quantum $m$ echanics.
$C$ an the structure of reasoning developed in this paper for non-relativistic quantum me chanics be extended to relativistic quantum mechanics and quantum eld theory? Various exam ples suggest that the sort of peculiar non-locality which is often thought to arise from violations of Bell's inequality and various EPR paradoxes will disappear when one enforoes the rule that consistent quantum argum ents must employ a single fram ew ork. W hile this is encouraging, it is also true that locality (or the lack thereof) in non-relativistic quantum theory has not yet been carefilly analyzed from the perspective presented in this paper, and hence $m$ ust be considered am ong the open questions. A nd, of course, getting rid of spurious non-localities is only a sm all step along the way tow ards a fiully relativistic theory.

Even in the dom ain ofnon-relativistic (and non-counterfactual) quantum reasoning, there is no proof that the schem e presented in this paper is appropriate and adequate for all of standard quantum $m$ echanics. Indeed, standard quantum $m$ echanics contains a great deal of seat-of-the-pants intuition which has never been form alized, and thus it is hard to think of any way of testing the system of reasoning presented here apart from applying it to a large num ber of exam ples, to see if it yields what the experts agree are the \right answers", and what the experim entalists nd in their laboratories. D uring the past ten years consistent history ideas have been applied to $m$ any di erent situations w ithout encountering serious problem s, but there is always the possibility that the fatal aw lies just around the next comer. If such a aw exists, it should not be hard to identify, since the schem e of reasoning presented in this paper has precise rules and is based on \straight" quantum mechanics, w ithout hidden variables, adjustable param eters, $m$ odi cations of the Schrodinger equation,
and excuses of the \for all practical purposes" type. The reader who considers it defective is invited to point out the problem s!
