We present a quantization procedure for the electromagnetic field in a circular cylindrical cavity with perfectly conducting walls, which is based on the decomposition of the field. A new decomposition procedure is proposed; all vector mode functions satisfying the boundary conditions are obtained with the help of this decomposition. After expanding the quantized field in terms of the vector mode functions, it is possible to derive the Hamiltonian for this quantized system.

1 Introduction

The behavior of an atom depends on the mode structure of the electromagnetic field surrounding it [1]. The mode structure in a cavity is determined by its boundary conditions which are quite different from the periodic boundary conditions used in Lorentz-covariant electrodynamics. There are many interesting effects on the interaction of the atom with the field with various boundary conditions. It is possible to calculate them and compare them with experimental data [2]. Thanks to many new "high-tech" experimental instruments, cavity electrodynamics has become one of the most active branches of physics in recent years.

In quantum electrodynamics, we use the plane waves satisfying the periodic boundary condition whose quantization volume eventually becomes infinite. As a result, the orientation of the field is not essential. On the other hand, the field in a cavity must satisfy the boundary conditions and the orientation of the field with respect to cavity walls becomes an important factor. For this reason, we have to use vector mode functions to deal with this problem. These functions satisfy the boundary conditions and the boundary effect in turn is contained in the functions. Thus, for a given cavity, the most important step in the quantization process is to construct the vector mode functions.

Indeed, several authors have investigated the quantization procedure for the field in cavities [3]. They have studied the field quantization, the emission rate, and the atomic level shifts in the cavities with one or two infinite plane mirrors. Cavity electrodynamics with rectangular coordinate system does not present further significant mathematical problems. However, the case is quite different for cavities with curved boundary conditions. Even for circular cylindrical or spherical cavities, the quantization procedure has not yet been firmly established. The purpose of the present paper is to discuss in detail the mathematical problems in constructing the vector mode functions with a circular cylindrical boundary condition. We hope to discuss the spherical cavity in a later paper.

Recently, we have carried out the field quantization for several different rectangular boundary conditions including a rectangular tube using the vector mode functions [4]. These functions have been derived with the help of an orthogonal matrix. However, the procedure developed there is not applicable to other cavities in a straightforward manner.

In this paper, we present a more general method of obtaining the vector mode functions and apply it to the field quantization in a circular cylindrical cavity with perfectly conducting walls. This will be summarized in two theorems.

With this in mind, we first decompose the field into three parts in the circular cylindrical coordinates in the following section. Then, in Sec. 3, we apply it to the circular cylindrical cavity. After obtaining all vector mode functions by using the decomposition, we arrive at the quantized field and the quantized electromagnetic Hamiltonian in Sec. 4.

2 Decomposition of Electromagnetic fields

Let us now derive the decomposition formula for the electromagnetic field from Maxwell's equations. Using the cylindrical coordinate system, we shall decompose the solutions of Maxwell's equations into three terms, in preparation for the field quantization within the

circular cylindrical cavity in Sec. 3. We emphasize here again that this decomposition process is the key to the quantization.

Maxwell's equations for the electric field \mathbf{E} and the magnetic field \mathbf{B} in free space are given by

$$\nabla \cdot \mathbf{E} = 0, \tag{2.1}$$

$$\nabla \cdot \mathbf{B} = 0, \tag{2.2}$$

$$\nabla \times \mathbf{E} + \partial_t \mathbf{B} = 0, \tag{2.3}$$

$$\nabla \times \mathbf{B} - \frac{1}{c^2} \partial_t \mathbf{E} = 0, \qquad (2.4)$$

where c is the velocity of light in free space and $\partial_t = \partial/\partial t$. As is well known, it follows from Maxwell's equations that the fields **E** and **B** satisfy the wave equations:

$$\left(\triangle -\frac{1}{c^2}\partial_t^2\right)\mathbf{E} = 0, \quad \left(\triangle -\frac{1}{c^2}\partial_t^2\right)\mathbf{B} = 0, \quad (2.5)$$

where \triangle is the Laplacian operator.

The electromagnetic field **E** and **B** can be written in the cylindrical coordinates (r, φ, z) as

$$\mathbf{E} = \mathbf{E}_T + \mathbf{E}_z, \quad \mathbf{B} = \mathbf{B}_T + \mathbf{B}_z, \tag{2.6}$$

where $\mathbf{E}_T = \mathbf{e}_r E_r + \mathbf{e}_{\varphi} E_{\varphi}$ is the transverse component of the field and $\mathbf{E}_z = \mathbf{e}_z E_z$. Here \mathbf{e}_r , \mathbf{e}_{φ} , and \mathbf{e}_z are the unit vectors in the r, φ , and z directions, respectively. Similarly, $\nabla \times \mathbf{E}$, $\nabla \cdot \mathbf{E}$, and $\nabla \phi$ (ϕ a scalar function) can also be divided into two parts. For example, $\nabla \times \mathbf{E} = \nabla_T \times \mathbf{E} + \nabla_z \times \mathbf{E}$, where the first term contains the derivatives with respect to rand φ , while the second term contains the derivative with respect to z. For simplicity, the derivatives with respect to r, φ , and z are described as $\partial/\partial r = \partial_r$, $\partial/\partial \varphi = \partial_{\varphi}$ and $\partial/\partial z = \partial_z$, respectively.

Since $\nabla_z \times \mathbf{E}_z = 0$, Eq. (2.3) gives

$$\partial_t \mathbf{B}_z = -\nabla_T \times \mathbf{E}_T, \quad \partial_t \mathbf{B}_T = -\nabla_T \times \mathbf{E}_z - \nabla_z \times \mathbf{E}_T.$$
 (2.7)

Similarly, from Eq. (2.4), we have

$$\frac{1}{c^2}\partial_t \mathbf{E}_z = \nabla_T \times \mathbf{B}_T, \quad \frac{1}{c^2}\partial_t \mathbf{E}_T = \nabla_T \times \mathbf{B}_z + \nabla_z \times \mathbf{B}_T.$$
(2.8)

Equations (2.7) and (2.8) give

$$\frac{1}{c^2}\partial_t^2 \mathbf{E}_T = \nabla_T \times \partial_t \mathbf{B}_z - \nabla_z \times (\nabla_T \times \mathbf{E}_z + \nabla_z \times \mathbf{E}_T),$$

$$\frac{1}{c^2}\partial_t^2 \mathbf{B}_T = -\frac{1}{c^2}\nabla_T \times \partial_t \mathbf{E}_z - \nabla_z \times (\nabla_T \times \mathbf{B}_z + \nabla_z \times \mathbf{B}_T),$$
(2.9)

which leads to

$$\frac{1}{c^2}\partial_t^2 \mathbf{E}_T + \nabla_z \times \nabla_z \times \mathbf{E}_T - \nabla_T \times \nabla_T \times \mathbf{E}_z = \nabla \times \partial_t \mathbf{B}_z - \nabla \times \nabla \times \mathbf{E}_z,
\frac{1}{c^2}\partial_t^2 \mathbf{B}_T + \nabla_z \times \nabla_z \times \mathbf{B}_T - \nabla_T \times \nabla_T \times \mathbf{B}_z = -\frac{1}{c^2}\nabla \times \partial_t \mathbf{E}_z - \nabla \times \nabla \times \mathbf{B}_z, (2.10)$$

where we have used $\nabla_T \times \mathbf{E}_z = \nabla \times \mathbf{E}_z$. Let us note that

$$\nabla_{z} \times \nabla_{z} \times \mathbf{E}_{T} = -\Delta_{z} \mathbf{E}_{T},$$

$$\nabla_{T} \times \nabla_{T} \times \mathbf{E}_{z} = -\Delta_{T} \mathbf{E}_{z},$$

$$\frac{1}{c^{2}} \partial_{t}^{2} \mathbf{E}_{T} = (\Delta \mathbf{E})_{T} = \Delta \mathbf{E}_{T},$$
(2.11)

where $(\Delta \mathbf{E})_T$ is the transverse part of $\Delta \mathbf{E}$; the last equation holds in the present coordinates, although it is not correct in general. (For example, it is not correct in the spherical coordinates.) Then, from Eq. (2.10), we arrive at

$$\Delta_T \mathbf{E} = -\nabla \times \nabla \times \mathbf{E}_z + \nabla \times \partial_t \mathbf{B}_z,$$

$$\Delta_T \mathbf{B} = -\frac{1}{c^2} \nabla \times \partial_t \mathbf{E}_z - \nabla \times \nabla \times \mathbf{B}_z.$$
 (2.12)

To rewrite Eq. (2.12), we must obtain an expression for the components E_z and B_z . Suppose that the field is in a finite region and expand E_z and B_z in terms of a certain complete system of functions with mode s:

$$E_z(\mathbf{r}, t) = \sum_s (E_{zs}(\mathbf{r}, t) + \text{c.c.}),$$

$$B_z(\mathbf{r}, t) = \sum_s (B_{zs}(\mathbf{r}, t) + \text{c.c.}),$$
(2.13)

where

$$E_{zs}(\mathbf{r},t) = \tilde{E}_{zs}(\mathbf{r})e^{-i\omega_{s1}t}, \quad B_{zs}(\mathbf{r},t) = \tilde{B}_{zs}(\mathbf{r})e^{-i\omega_{s2}t}.$$
(2.14)

Here $\omega_{s\sigma}$ ($\omega_{s\sigma} \ge 0$, $\sigma = 1, 2$) is determined by using given boundary conditions. Since E_z and B_z satisfy the wave equation, their components satisfy the Helmholtz equations:

$$\Delta E_{zs} = -k_{s1}^2 E_{zs}, \quad \Delta B_{zs} = -k_{s2}^2 B_{zs}, \tag{2.15}$$

where

$$k_{s\sigma}^2 = \frac{\omega_{s\sigma}^2}{c^2}.$$
 (2.16)

We assume that the components satisfy

$$\partial_z^2 E_{zs} = -h_{s1}^2 E_{zs}, \quad \partial_z^2 B_{zs} = -h_{s2}^2 B_{zs},$$
(2.17)

where $h_{s\sigma}^2$ is also determined by the boundary conditions. Then we have two dimensional Helmholtz equations:

$$\Delta_T E_{zs} = -g_{s1}^2 E_{zs}, \quad \Delta_T B_{zs} = -g_{s2}^2 B_{zs}, \tag{2.18}$$

where

$$g_{s\sigma}^2 = k_{s\sigma}^2 - h_{s\sigma}^2. \tag{2.19}$$

Now we define two functions F_{σ} from E_{zs} and B_{zs} with $g_{s\sigma}^2 \neq 0$ as

$$F_{\sigma}(\mathbf{r},t) = \sum_{g_{s\sigma}^2 \neq 0} [F_{s\sigma}(\mathbf{r},t) + \text{c.c.}] = \sum_{g_{s\sigma}^2 \neq 0} [\tilde{F}_{s\sigma}(\mathbf{r}) e^{-i\omega_{s\sigma}t} + \text{c.c.}], \qquad (2.20)$$

where

$$F_{s1} = E_{zs}/g_{s1}^2, \quad F_{s2} = B_{zs}/g_{s2}^2.$$
 (2.21)

The functions F_{σ} and their components $F_{s\sigma}$ satisfy the same equations as the z components of the field:

$$\Delta F_{\sigma} = -\frac{1}{c^2} \frac{\partial}{\partial_t} F_{\sigma}, \qquad \Delta_T F_{s\sigma} = -g_{s\sigma}^2 F_{s\sigma}$$
(2.22)

From Eqs. (2.21) and (2.22) the component $F_{s\sigma}$ is a solution of the Poisson equation

$$\Delta_T F_{s1} = -E_{zs}, \quad \Delta_T F_{s2} = -B_{zs} \tag{2.23}$$

and then the functions $\triangle_T F_{\sigma}$ satisfy

$$\Delta_T F_1 = -\sum_{\substack{g_{s_1}^2 \neq 0}} (g_{s_1}^2 F_{s_1} + \text{c.c.}) = -\sum_{\substack{g_{s_1}^2 \neq 0}} (E_{zs} + \text{c.c.}),$$

$$\Delta_T F_2 = -\sum_{\substack{g_{s_2}^2 \neq 0}} (g_{s_2}^2 F_{s_2} + \text{c.c.}) = -\sum_{\substack{g_{s_2}^2 \neq 0}} (B_{zs} + \text{c.c.}).$$
(2.24)

On the other hand, if there is a component E_{zs} or B_{zs} with $g_{s\sigma}^2 = 0$, Eq. (2.18) reduces to the two dimensional Laplace equation: $\Delta_T E_{zs} = 0$ or $\Delta_T B_{zs} = 0$. Now define E_{0z} and B_{0z} as

$$E_{0z} = \sum_{g_{s1}^2 = 0} (E_{zs} + \text{c.c.}), \quad B_{0z} = \sum_{g_{s2}^2 = 0} (B_{zs} + \text{c.c.}), \quad (2.25)$$

which satisfy

$$\Delta_T E_{0z} = 0, \quad \Delta_T B_{0z} = 0. \tag{2.26}$$

Then we have a useful expression for E_z and B_z ; for any E_z and B_z there exist functions F_{σ} given by Eq. (2.20) and functions E_{0z} and B_{0z} are given by Eq. (2.25) such that

$$E_z = -\Delta_T F_1 + E_{0z}, \quad B_z = -\Delta_T F_2 + B_{0z}.$$
 (2.27)

It is worth emphasizing again that the functions F_{σ} are constructed with the components E_{zs} and B_{zs} with $g_{s\sigma}^2 \neq 0$, while E_{0z} and B_{0z} consist of the components with $g_{s\sigma}^2 = 0$.

Using Eq. (2.27) and defining \mathbf{F}_{σ} by

$$\mathbf{F}_{\sigma} = \mathbf{e}_z F_{\sigma},\tag{2.28}$$

we can rewrite Eq. (2.12) as

$$\Delta_T \Big(\mathbf{E} - \nabla \times \nabla \times \mathbf{F}_1 + \nabla \times \partial_t \mathbf{F}_2 \Big) = -\nabla \times \nabla \times \mathbf{E}_{0z} + \nabla \times \partial_t \mathbf{B}_{0z}, \qquad (2.29)$$

$$\Delta_T \left(\mathbf{B} - \frac{1}{c^2} \nabla \times \partial_t \mathbf{F}_1 - \nabla \times \nabla \times \mathbf{F}_2 \right) = -\frac{1}{c^2} \nabla \times \partial_t \mathbf{E}_{0z} - \nabla \times \nabla \times \mathbf{B}_{0z}, \quad (2.30)$$

where $\mathbf{E}_{0z} = \mathbf{e}_z E_{0z}$ and $\mathbf{B}_{0z} = \mathbf{e}_z B_{0z}$. Let us define \mathbf{E}_0 and \mathbf{B}_0 as the quantities in the parentheses at the left hand side in Eqs. (2.29) and (2.30), respectively. The results of this section are then summarized in the following theorem.

Theorem 1: The field can be decomposed into three components as follows:

$$\mathbf{E} = \nabla \times \nabla \times \mathbf{F}_1 - \nabla \times \partial_t \mathbf{F}_2 + \mathbf{E}_0, \mathbf{B} = \frac{1}{c^2} \nabla \times \partial_t \mathbf{F}_1 + \nabla \times \nabla \times \mathbf{F}_2 + \mathbf{B}_0,$$
(2.31)

where \mathbf{E}_0 and \mathbf{B}_0 satisfy

$$\Delta_T \mathbf{E}_0 = -\nabla \times \nabla \times \mathbf{E}_{0z} + \nabla \times \partial_t \mathbf{B}_{0z},$$

$$\Delta_T \mathbf{B}_0 = -\frac{1}{c^2} \nabla \times \partial_t \mathbf{E}_{0z} - \nabla \times \nabla \times \mathbf{B}_{0z}.$$
 (2.32)

Theorem 1 plays a central role in performing field quantization in this paper. Take the z component of Eq. (2.31), we find that the z components of \mathbf{E}_0 and \mathbf{B}_0 are given by E_{0z} and B_{0z} in Eq. (2.27), respectively. Furthermore, Eq. (2.32) is consistent with Eq. (2.12).

Let us consider the physical meaning of the above decomposition formula. First it is worth emphasizing that each term in Eq. (2.31) is a solution to Maxwell's equations. That is, each term containing F_{σ} (F_{σ} term) satisfies Eqs. (2.1) - (2.4), which is easily shown by using the fact that F_{σ} satisfies the wave equation (2.22). As a result, the third term \mathbf{E}_0 , \mathbf{B}_0 is also a solution to Maxwell's equations, so that it satisfies Eq. (2.12), as mentioned above.

Next take a particular example of the boundary condition satisfying E_{0z} , $B_{0z} = 0$. Then the field \mathbf{E}_0 , \mathbf{B}_0 describes so-called the TEM (transverse electromagnetic) mode [5]. Since the F_1 term has no z component of the magnetic field, it becomes TM (transverse magnetic), while the F_2 term becomes TE (transverse electric), because it does not contain the z component of the electric field.

In the above particular case where $E_{0z}, B_{0z} = 0$, Maxwell's equations for the field $\mathbf{E}_0, \mathbf{B}_0$ reduce to

$$\nabla_T \cdot \mathbf{E}_0 = 0, \quad \nabla_T \times \mathbf{E}_0 = 0,$$

$$\nabla_T \cdot \mathbf{B}_0 = 0, \quad \nabla_T \times \mathbf{B}_0 = 0,$$

$$\nabla_z \times \mathbf{E}_0 + \partial_t \mathbf{B}_0 = 0,$$

$$\nabla_z \times \mathbf{B}_0 - \frac{1}{c^2} \partial_t \mathbf{E}_0 = 0.$$
(2.33)

3 Determination of Functions F_{σ}

We are considering here the cavity enclosed by a circular cylindrical wall with radius a and height L: r < a, 0 < z < L. We assume that the cavity has perfectly conducting walls at z = 0, L and at r = a. The tangential component of the electric field $\mathbf{E}|_{\text{tan}}$ and the normal component of the magnetic field $\mathbf{B}|_{\text{norm}}$ must accordingly vanish at the boundary of the cavity.

The above boundary condition reduces to that for the z components

$$E_z = 0, \quad \partial_r B_z = 0, \qquad (r = a), \tag{3.1}$$

$$B_z = 0, \quad \partial_z E_z = 0, \qquad (z = 0, L).$$
 (3.2)

It is easy to get the second condition in Eq. (3.1) if we take the φ component of Eq. (2.4). Equation (2.1) leads to the second condition in Eq. (3.2).

Before obtaining the components E_{zs} and B_{zs} , we show that the following lemma.

Lemma 1: $\mathbf{E}_0 = 0, \ \mathbf{B}_0 = 0.$

Proof: First we show that E_{0z} , $B_{0z} = 0$. Consider the component E_{0z} , which satisfies the Laplace equation $\Delta_T E_{0z} = 0$ [see Eq. (2.26)] with the boundary condition $E_{0z} = 0$ at the boundary (r = a). Then we have $E_{0z} = 0$; this is a well known property of the Laplace equation.

Next consider the component B_{0z} satisfying $\Delta_T B_{0z} = 0$ with the boundary condition $\partial_r B_{0z} = 0$ (r = a). Then B_{0z} must be a constant, i.e., independent of the variables r and φ : $B_{0z} = f(z, t)$. Applying the two-dimensional Gauss' theorem to $\nabla \cdot \mathbf{B}_0 = \nabla_T \cdot \mathbf{B}_{0T} + \partial_z B_{0z} = 0$, we get $\partial_z B_{0z} = 0$, because $B_{0r} = 0$ (r = a) and, as a result, B_{0z} is independent of the variables r, φ , and z. On the other hand, B_{0z} must be zero at z = 0, L, which leads to $B_{0z} = 0$.

As mentioned in the preceding section, the field \mathbf{E}_0 , \mathbf{B}_0 becomes TEM satisfying Eq. (2.33), because E_{0z} , $B_{0z} = 0$. There exists no TEM in the present cavity. That is, from Eq. (2.33) we have $\nabla_T \times \mathbf{B}_0 = 0$ and $\nabla_T \cdot \mathbf{B}_0 = 0$. As a result, there exists a function φ such that $\mathbf{B}_0 = -\nabla_T \varphi$, which gives $\mathbf{B}_0 = 0$ by the boundary condition at r = a. Similarly, we get a vector function \mathbf{A} such that $\mathbf{E}_0 = \nabla \times \mathbf{A}$. The boundary condition leads us to $\mathbf{E}_0 = 0$. Q.E.D.

Since $\mathbf{E}_0, \mathbf{B}_0 = 0$, Theorem 1 shows that the field is constructed from the functions F_{σ} . Consequently, from Eq. (2.20), the field only contains the components with $g_{s\sigma}^2 \neq 0$. Moreover, it is easy to prove that $g_{s\sigma}^2 > 0$ by using Gauss' theorem and the boundary condition.

Next we solve the Helmholtz equation (2.15) for the components E_{zs} and B_{zs} under the boundary conditions (3.1) and (3.2). Since $g_{s\sigma}^2 > 0$, the solution is given by

$$E_{zs}(\mathbf{r},t) = C_{s1}(t)J_m(\chi_{s1}r/a) e^{im\varphi}\cos(n\pi z/L),$$

$$B_{zs}(\mathbf{r},t) = C_{s2}(t)J_m(\chi_{s2}r/a) e^{im\varphi}\sin(n\pi z/L),$$
(3.3)

where the mode index is $s = (m, \mu, n)$ $(m = 0, \pm 1, \pm 2, \dots; \mu = 1, 2, 3, \dots; n = 0, 1, 2, \dots)$, J_m is the Bessel function of the first kind, $\chi_{s1} \equiv \chi_{m\mu 1}$ is the μ th zero point of J_m , and $\chi_{s2} \equiv \chi_{m\mu 2}$ is the μ th zero point of J'_m , the derivative of J_m . It follows from Eq. (2.14) that $C_{s\sigma}(t) \propto \exp(-i\omega_{s\sigma}t)$.

From the solution (3.3) we have

$$\Delta_T E_{zs} = -(k_{s1}^2 - (n\pi/L)^2)E_{zs} = -(\chi_{s1}/a)^2 E_{zs},$$

$$\Delta_T B_{zs} = -(k_{s2}^2 - (n\pi/L)^2)B_{zs} = -(\chi_{s2}/a)^2 B_{zs},$$
(3.4)

which gives

$$g_{s\sigma}^2 = (\chi_{s\sigma}/a)^2, \quad k_{s\sigma}^2 = (\chi_{s\sigma}/a)^2 + (n\pi/L)^2.$$
 (3.5)

Let us next obtain the functions F_{σ} , which are defined in Eqs. (2.20) and (2.21); they are given by

$$F_{s1}(\mathbf{r},t) = \frac{a^2 E_{zs}(\mathbf{r},t)}{\chi_{s1}^2} \equiv i \sqrt{\frac{\hbar\omega_{s1}}{2\varepsilon_0}} a_{s1}(t) \psi_{s1}(\mathbf{r}),$$

$$F_{s2}(\mathbf{r},t) = \frac{a^2 B_{zs}(\mathbf{r},t)}{\chi_{s2}^2} \equiv i \sqrt{\frac{\hbar\omega_{s2}}{2\varepsilon_0}} a_{s2}(t) \psi_{s2}(\mathbf{r}), \qquad (3.6)$$

where we have introduced $a_{s\sigma}$ and $\psi_{s\sigma}$:

$$a_{s\sigma}(t) = a_{s\sigma}(0)e^{-i\omega_{s\sigma}t},\tag{3.7}$$

$$\psi_{s1}(\mathbf{r},t) = c_{s1} J_m(\chi_{s1}r/a) e^{im\varphi} \cos(n\pi z/L), \qquad (3.8)$$

$$\psi_{s2}(\mathbf{r},t) = c_{s2}J_m(\chi_{s2}r/a)\,e^{im\varphi}\sin(n\pi z/L),\tag{3.9}$$

where $c_{s\sigma}$ are normalization constants. The functions $\psi_{s\sigma}$ have the orthonormality property, which is used in quantization in the next section.

Lemma 2:

$$\int_{c} d\mathbf{r} \,\psi_{s\sigma}^{*}(\mathbf{r})\psi_{s'\sigma}(\mathbf{r}) = \frac{1}{2} |c_{s\sigma}|^{2} V \alpha_{s\sigma} \delta_{ss'}, \qquad (3.10)$$

where $\int_{c} d\mathbf{r} = \int_{cavity} r dr d\varphi dz$, V is the cavity volume, and

$$\alpha_{s1} \equiv \alpha_{m\mu1} = J_{m+1}^2(\chi_{m\mu1}),$$

$$\alpha_{s2} \equiv \alpha_{m\mu2} = J_m^2(\chi_{m\mu2}) - J_{m+1}^2(\chi_{m\mu2}).$$
(3.11)

Here the quantity $\cos(n\pi z/L)$ in Eq. (3.8) must be changed to $1/\sqrt{2}$ when n = 0.

Proof: The orthonormality property (3.10) is easily derived from the following equality for the Bessel functions:

$$\int_{0}^{a} dr \, r J_{m}(\chi_{m\mu\sigma}r/a) J_{m}(\chi_{m\mu'\sigma}r/a) = \frac{1}{2} \, a^{2} \alpha_{s\sigma} \, \delta_{\mu\mu'}. \tag{3.12}$$

To prove Eq. (3.12), let us first observe the following two integrals [6]

$$\int_{0}^{1} dx \, x J_{m}(\chi_{i}x) J_{m}(\chi_{j}x) = \frac{1}{\chi_{i}^{2} - \chi_{j}^{2}} \Big[\chi_{i} J_{m+1}(\chi_{i}) J_{m}(\chi_{j}) - \chi_{j} J_{m+1}(\chi_{j}) J_{m}(\chi_{i}) \Big] \\ = \frac{1}{\chi_{i}^{2} - \chi_{j}^{2}} \Big[-\chi_{i} J_{m}'(\chi_{i}) J_{m}(\chi_{j}) + \chi_{j} J_{m}(\chi_{i}) J_{m}'(\chi_{j}) \Big]$$
(3.13)

$$\int_{0}^{1} dx \, x J_{m}^{2}(\chi_{i}x) = \frac{1}{2} \Big[J_{m}^{2}(\chi_{i}) - J_{m-1}(\chi_{i}) J_{m+1}(\chi_{i}) \Big] \\ = \frac{1}{2} \Big[J_{m}^{2}(\chi_{i}) - J_{m+1}^{2}(\chi_{i}) - 2J_{m}'(\chi_{i}) J_{m+1}(\chi_{i}) \Big], \quad (3.14)$$

where χ_i $(i = 1, 2, \dots)$ is a positive real number and $\chi_i \neq \chi_j$.

Considering that $\chi_{m\mu 1}$ is the μ th zero point of $J_m(x)$ and that $J_{m-1}(\chi_{m\mu 1}) + J_{m+1}(\chi_{m\mu 1}) = 0$, from Eqs. (3.13) and (3.14), we have

$$\int_0^1 dx \, x J_m(\chi_{m\mu 1} x) J_m(\chi_{m\mu' 1} x) = \frac{1}{2} \alpha_{m\mu 1} \, \delta_{\mu\mu'}, \qquad (3.15)$$

where $\alpha_{m\mu 1}$ is given by Eq. (3.11). If we change the variable x to r/a, Eq. (3.15) gives Eq. (3.12) for $\sigma = 1$.

Similarly, Eqs. (3.13) and (3.14) lead to

$$\int_0^1 dx \, x J_m(\chi_{m\mu 2} x) J_m(\chi_{m\mu' 2} x) = \frac{1}{2} \alpha_{m\mu 2} \, \delta_{\mu\mu'}, \qquad (3.16)$$

where $\alpha_{m\mu 2}$ is given by Eq. (3.11). Equation (3.16) gives us Eq. (3.12) for $\sigma = 2$. Q.E.D.

4 Vector Mode Functions and Field Quantization

After defining the vector mode functions, we quantize the field and obtain the quantized Hamiltonian. The mode functions are constructed according to the decomposition formula given in Eq. (2.31)

In the cavity with the perfectly conducting walls, the decomposition (2.31) in Theorem 1 reduces to

$$\mathbf{E} = \nabla \times \nabla \times \mathbf{F}_1 - \nabla \times \partial_t \mathbf{F}_2, \mathbf{B} = \frac{1}{c^2} \nabla \times \partial_t \mathbf{F}_1 + \nabla \times \nabla \times \mathbf{F}_2,$$
(4.1)

because of $\mathbf{E}_0, \mathbf{B}_0 = 0$ [see Lemma 1].

Substituting the functions F_{σ} in Eq. (3.6) into **E** in Eq. (4.1), we find

$$\mathbf{E}(\mathbf{r},t) = i \sum_{s\sigma} \sqrt{\frac{\hbar\omega_{s\sigma}}{2\varepsilon_0}} \Big[a_{s\sigma}(t) \mathbf{u}_{s\sigma}(\mathbf{r}) - a_{s\sigma}^*(t) \mathbf{u}_{s\sigma}^*(\mathbf{r}) \Big], \tag{4.2}$$

where the vector mode functions $\mathbf{u}_{s\sigma}$ are given by

 $\mathbf{u}_{s1} = \nabla \times \nabla \times \mathbf{e}_z \psi_{s1}, \quad \mathbf{u}_{s2} = i\omega_{s2} \nabla \times \mathbf{e}_z \psi_{s2}. \tag{4.3}$

Similarly, substituting F_{σ} into **B** and considering the equality

$$\nabla \times \mathbf{u}_{s1} = k_{s1}^2 \nabla \times \mathbf{e}_z \psi_{s1}, \tag{4.4}$$

we obtain

$$\mathbf{B}(\mathbf{r},t) = \sum_{s\sigma} \sqrt{\frac{\hbar}{2\varepsilon_0 \omega_{s\sigma}}} \Big[a_{s\sigma}(t) \nabla \times \mathbf{u}_{s\sigma}(\mathbf{r}) + a_{s\sigma}^*(t) \nabla \times \mathbf{u}_{s\sigma}^*(\mathbf{r}) \Big].$$
(4.5)

Before obtaining the quantized field and Hamiltonian, let us present some properties of the mode functions.

Lemma 3:

$$\nabla \cdot \mathbf{u}_{s\sigma} = 0, \tag{4.6}$$

$$(\Delta + k_{s\sigma}^2)\mathbf{u}_{s\sigma} = 0, \tag{4.7}$$

$$\mathbf{u}_{s\sigma}|_{\mathrm{tan}} = 0, \quad \nabla \times \mathbf{u}_{s\sigma}|_{\mathrm{norm}} = 0, \quad (\mathrm{on \ walls}),$$

$$(4.8)$$

$$\int_{\mathbf{c}} d\mathbf{r} \, \mathbf{u}_{s\sigma}^{*}(\mathbf{r}) \cdot \mathbf{u}_{s'\sigma'}(\mathbf{r}) = \delta_{ss'} \, \delta_{\sigma\sigma'}, \qquad (4.9)$$

Proof: We give a proof of the orthonormality property (4.9), because it is obvious to prove the other equations. From Eq. (4.3), the mode function \mathbf{u}_{s1} is rewritten as

$$\mathbf{u}_{s1} = \nabla (\nabla \cdot \mathbf{e}_z \psi_{s1}) - \triangle \mathbf{e}_z \psi_{s1} = k_{s1}^2 \mathbf{e}_z \psi_{s1} + \nabla (\partial_z \psi_{s1}), \qquad (4.10)$$

which gives

$$\mathbf{u}_{s1}^{*} \cdot \mathbf{u}_{s'1} = \begin{bmatrix} k_{s1}^{2} k_{s'1}^{2} - k_{s1}^{2} h_{s'1}^{2} \end{bmatrix} \psi_{s1}^{*} \psi_{s'1} \\ + k_{s'1}^{2} \partial_{z} \Big[(\partial_{z} \psi_{s1}^{*}) \psi_{s'1} \Big] + \nabla \Big[(\partial_{z} \psi_{s1}^{*}) \nabla \partial_{z} \psi_{s'1} \Big].$$
(4.11)

Taking into account Gauss' theorem and the boundary conditions, we find that the last two terms in Eq. (4.11) have no effect on the volume integration of $\mathbf{u}_{s1}^* \cdot \mathbf{u}_{s'1}$. Equation (4.11) gives the orthonormality relation for \mathbf{u}_{s1} :

$$\int_{c} d\mathbf{r} \, \mathbf{u}_{s1}^{*}(\mathbf{r}) \cdot \mathbf{u}_{s'1}(\mathbf{r}) = \delta_{ss'}, \qquad (4.12)$$

where we have used Eq. (3.10) and set

$$c_{s1} = \sqrt{\frac{2c^2 a^2}{V \alpha_{s1} \chi_{s1}^2 \omega_{s1}^2}}.$$
(4.13)

In the case of \mathbf{u}_{s2} , we make use of the equality

$$(\nabla \times \mathbf{e}_{z}\psi_{s2}^{*}) \cdot (\nabla \times \mathbf{e}_{z}\psi_{s'2}) = \mathbf{e}_{z}\psi_{s2}^{*} \cdot (\nabla \times \nabla \times \mathbf{e}_{z}\psi_{s'2}) + \nabla \cdot \left[\mathbf{e}_{z}\psi_{s2}^{*} \times (\nabla \times \mathbf{e}_{z}\psi_{s'2})\right]$$

$$= \frac{\chi_{s'2}^{2}}{a^{2}}\psi_{s2}^{*}\psi_{s'2} + \nabla \cdot (\psi_{s2}^{*}\nabla_{T}\psi_{s'2}).$$

$$(4.14)$$

The orthonormality property of \mathbf{u}_{s2} is then obtained from Eq. (3.10) if we set the normalization constant:

$$c_{s2} = \sqrt{\frac{2a^2}{V\alpha_{s2}\chi_{s2}^2\omega_{s2}^2}}.$$
(4.15)

Finally we show that the mode functions \mathbf{u}_{s1} and $\mathbf{u}_{s'2}$ are orthogonal to each other. Since \mathbf{u}_{s2} has no z component, we see that

$$\mathbf{u}_{s1}^{*} \cdot \mathbf{u}_{s'2} = i\omega_{s'2} \Big(k_{s1}^{2} \mathbf{e}_{z} \psi_{s1}^{*} + \nabla \partial_{z} \psi_{s1}^{*} \Big) \cdot (\nabla \times \mathbf{e}_{z} \psi_{s'2}) \\
= i\omega_{s'2} \nabla (\partial_{z} \psi_{s1}^{*}) \cdot (\nabla \times \mathbf{e}_{z} \psi_{s'2}) \\
= i\omega_{s'2} \nabla \cdot \Big[(\partial_{z} \psi_{s1}^{*}) (\nabla \times \mathbf{e}_{z} \psi_{s'2}) \Big],$$
(4.16)

which has no effect on the volume integration of $\mathbf{u}_{s1}^* \cdot \mathbf{u}_{s'2}$. Q.E.D.

We are now ready to carry out the field quantization. To get the quantized field the functions $a_{s\sigma}(t)$ are regarded as annihilation operators, which annihilate photons with indices $s\sigma$ and satisfy the commutation relation:

$$[a_{s\sigma}(t), a^{\dagger}_{s'\sigma'}(t)] = \delta_{ss'}\delta_{\sigma\sigma'}, \qquad (4.17)$$

where $a^{\dagger}_{s'\sigma'}(t)$ are creation operators. Then the field given by Eqs. (4.2) and (4.5) becomes operators. The quantized electromagnetic Hamiltonian H_R is obtained by using the equality

$$\int_{c} d\mathbf{r} \left(\nabla \times \mathbf{u}_{s\sigma}^{*}(\mathbf{r}) \right) \cdot \left(\nabla \times \mathbf{u}_{s'\sigma'}(\mathbf{r}) \right) = k_{s'\sigma'}^{2} \int_{c} d\mathbf{r} \, \mathbf{u}_{s\sigma}^{*}(\mathbf{r}) \cdot \mathbf{u}_{s'\sigma'}(\mathbf{r}). \tag{4.18}$$

These are summarized in the following theorem.

Theorem 2: The quantized field and the Hamiltonian are given by

$$\mathbf{E}(\mathbf{r},t) = i \sum_{s\sigma} \sqrt{\frac{\hbar\omega_{s\sigma}}{2\varepsilon_0}} \Big[a_{s\sigma}(t) \mathbf{u}_{s\sigma}(\mathbf{r}) - a_{s\sigma}^{\dagger}(t) \mathbf{u}_{s\sigma}^{*}(\mathbf{r}) \Big],$$
(4.19)

$$\mathbf{B}(\mathbf{r},t) = \sum_{s\sigma} \sqrt{\frac{\hbar}{2\varepsilon_0 \omega_{s\sigma}}} \Big[a_{s\sigma}(t) \nabla \times \mathbf{u}_{s\sigma}(\mathbf{r}) + a_{s\sigma}^{\dagger}(t) \nabla \times \mathbf{u}_{s\sigma}^{*}(\mathbf{r}) \Big].$$
(4.20)

$$H_R = \sum_{s\sigma} \frac{1}{2} \hbar \omega_{s\sigma} \left(a_{s\sigma}^{\dagger} a_{s\sigma} + a_{s\sigma} a_{s\sigma}^{\dagger} \right) = \sum_{s\sigma} \hbar \omega_{s\sigma} \left(a_{s\sigma}^{\dagger} a_{s\sigma} + \frac{1}{2} \right).$$
(4.21)

Theorem 2 will play a fundamental role when we investigate the electromagnetic property of a physical system in the circular cylindrical cavity. There are also important issues in the present cavity including, for example, spontaneous (stimulated) emission, absorption, the atomic energy shifts, and the Casimir effect; they will be investigated with the help of Theorem 2.

It is necessary to expand the field in terms of the vector mode functions as in Theorem 2. According to Fourier analysis, the field can be expanded in terms of, for instance, the periodic functions as in ordinary quantum electrodynamics. However, in this case, the operators $a_{s\sigma}$ and $a_{s\sigma}^{\dagger}$ cannot describe the physical photons. Consider the situation where the field consists of only one mode corresponding to the photon with $a_{s\sigma}\mathbf{u}_{s\sigma}$, where $\mathbf{u}_{s\sigma}$ satisfies the periodic boundary condition. This must be impossible, because this field does not satisfy the boundary conditions; the photon is then fictitious.

5 Conclusions

The quantization procedure of the field in the cavity without \mathbf{E}_0 , \mathbf{B}_0 is as follows: (a) obtain the decomposition formula (2.31) in the circular cylindrical coordinates; (b) solve the Helmholtz equations (2.15) for the components E_{zs} and B_{zs} under the boundary conditions (3.1) and (3.2); (c) determine the functions F_{σ} , which are the solutions of the Poisson equation (2.23), from E_{zs} , B_{zs} ; (d) substitute F_{σ} into the decomposition formula (2.31) and obtain the vector mode functions satisfying the orthonormality property (4.9); (e) then we arrive at the quantized field and Hamiltonian in Theorem 2.

As has been shown explicitly in Theorem 2 in Sec. 4, the energy $\hbar\omega_{s\sigma}$ of the photon depends on the polarization index as well as the wave number index. This is one of the characteristics of the circular cylindrical cavity. The photon energy is independent of the polarization index in a rectangular cavity and in free space.

In the entire process of quantization, the decomposition formula in Theorem 1 plays the essential role. We must find such a formula in an appropriate coordinate system if we study other types of cavities. Also, if a cavity allows the third term \mathbf{E}_0 , \mathbf{B}_0 in (2.31), we have to construct a methodology to deal with the problem. We hope to discuss the quantization of electromagnetic fields inside a spherical cavity in a future publication.

Acknowledgments

We would like to thank Prof. Y. Ezawa, Dr. R. Ray, Dr. G. Gat, Dr. S. Kobayashi, Dr. Kurennoy, and Mr. K. Ohshiro for numerous valuable discussions. We are also grateful to Prof. M. S. Kim for bringing some of the references to our attention.
