(February 7, 2022)

We present a quantum error correcting code that is invariant under the conditional time evolution between spontaneous emissions and which can correct for one general error. The code presented here generalizes previous error correction codes in that not all errors lead to di erent error syndrom es. This idea may lead to shorter codes than previously expected.

I. IN TRODUCTION

W ith the discovery of an algorithm to factorize a large num ber on a quantum com puter in polynom ial tim e instead of exponential time as required by a classical com puter [1], the question of how to im plem ent such a quantum computer has received considerable attention [2]. However, realistic estimates soon showed that decoherence processes and spontaneous emission severely limit the bit size of the number that can be factorized [3,4]. It has become clear that the solution to the problem does not lie in an increase in the lifetim e of the transitions used in the computation. Attention has now shifted towards the investigation of methods to encode qubits such that the correction of errors due to interaction with the environm ent becom es possible. In a num ber of recent publications, possible encoding schemes have been considered and theoretical work has been undertaken to elucidate the structure of quantum error correction codes [5{22]. However, we show that these codes do not perfectly correct errors due to the conditional time evolution [23] between spontaneous emissions. This has the e ect that for example the encoded lower state of a qubit, which, if unencoded, is not in uenced by the conditional time evolution, acquires an error due to the conditional time evolution. We then proceed to construct a code that is able to correct one general error and is able to correct to all orders the errors due to the conditional time evolution between spontaneous em issions. By one general error we mean an arbitrary one bit operation acting on a single bit of the code. The conditional time evolution, however, contains terms that act on many qubits. Our code proposed in this paper is the rst code that has the ability to correct a special kind of error (here due to the conditional time evolution) to all orders. This is an interesting feature, as one would be interested to correct those errors which frequently occur to higher order than rare errors. The code presented here is optimal in the

sense that it uses the smallest possible number of qubits required to perform its task (correcting one general error and all errors due to the conditional time evolution).

II. SINGLE ERROR CORRECTING CODES

Several codes have been proposed to encode one qubit which can correct one general error, i.e. am plitude and phase error or a com bination of both applied to the sam e qubit. An exam ple [10] of such a code is one where state jbi is represented by

$$\mathcal{D}_{L}i = \mathcal{D}0000i + \mathcal{1}1100i \mathcal{1}0011i \mathcal{D}1111i$$

+ $\mathcal{1}1010i + \mathcal{D}0110i + \mathcal{D}1001i + \mathcal{1}0101i$ (1)

and the state jliby

where the subscript L indicates that the encoded state ji i di ers from the initial state jii. W e om it the obvious normalization factor in the states D_{I} i and J_{I} i throughout this letter as they are irrelevant for the present analysis. Starting with a state j i = 10i + 11i, this is encoded as $j_L i = \mathcal{D}_L i + \mathcal{J}_L i$. If the state su ers an amplitude error A_i (which acts as a NOT operation on qubit i) or a phase error P_i (which gives the upper state of qubit i a m inus sign) or the com bination A_iP_i of both to the ith qubit of j L i it is possible to reconstruct the initial state j i. The code given in eqs. (1) - (2)has the attractive feature that it is optim al in the sense that it only requires 5 qubits which can be shown to be the m in in alpossible num ber [13]. U sing ideas sim ilar to classical error correcting codes one can estim ate that if one wants to encode l qubits in term s of n qubits in such a way that one can reconstruct the state after t general errors, then the inequality

$$2^{1} \begin{array}{c} X^{t} & n \\ 3^{1} & 3^{1} & 2^{n} \\ \vdots & \vdots \end{array}$$
(3)

has to be satis ed [11]. The bound eq. (3) is related to the sphere packing bound in classical coding theory [24]. The reason for that is that eq. (3) was obtained using the assumption that di erent errors lead to di erent mutually orthogonal error syndrom es. However, we will later see that the code presented in this paper (like the one presented in [5]) in fact violates this assumption which shows that it may be possible to nd codes that go beyond eq. (3).

The code given in eqs. (1) - (2) does not correct for multiple errors. Especially, it is not able to correct to all orders for errors that arise due to the conditional time evolution between spontaneous emissions. The conditional time evolution between spontaneous emissions is unavoidable and it diers from the unit operation because the fact that no spontaneous emission has taken place provides inform ation about the state of the system and therefore changes its wave function. The conditional time evolution of the system under the assumption that no spontaneous emission has taken place is given by the non-unitary time evolution operator expf $iH_{eff}t=hg$ [23]. For the case that the qubits are not driven by external elds we obtain for the code given in eqs. (1) - (2) the elds we are the more than the operator

$$H_{eff} = \begin{array}{c} X^5 \\ \text{ih} \\ \underset{i=1}{\overset{(i)}{11}}; \end{array}$$
(4)

where $^{(i)}_{11}$ is the projector jlihl jonto the excited state of the ith qubit leaving all other qubits una ected. 2 is the E instein coe cient of the upper level 1 of the qubits. If we apply the conditional time evolution exp(iH_{eff}t=h) to the encoded state

$$j_{L}i = j D_{L}i + j I_{L}i$$
 (5)

and subsequently apply the appropriate error correction procedure for this 5-bit code [10] we do not recover the original state. This becomes obvious in the special case t 1 in which one obtains

This shows that this 5-bit code is not able to correct errors due to the conditional time evolution exactly. Especially striking is the e ect when we assume that = 0, ie. we encode the (stable) ground state. The conditional time evolution then leads to no errors in the unencoded state while it changes the encoded state such that it cannot be corrected perfectly anym ore. Note, how ever, that the error introduced by the conditional time evolution is, for short times, of fourth order. If, how ever, a spontaneous emission (or any other kind of error) occurs then a subsequent conditional time evolution induces contributions which after error correction lead to second order errors in the state. O ur code presented later in this paper preserves the encoded state in both cases perfectly, is. to all orders.

The reason that the code eqs. (1)-(2) cannot perfectly correct errors due to the conditional time evolution derives from the fact that the words (product states) of

which the code consists do not all have the same number of excited states. This leads to a di erence in the rate at which the amplitude of these states decays. The amplitude of p00001 rem ains unchanged under the conditional tim e evolution while the am plitude of jl1100i for exam ple decreases at a rate exp(3 t). This can be seen as a multiple amplitude error with which the code can not cope. This problem is not restricted to the 5-bit code given in [10] but is present in all other previously proposed codes. It should be noted that it is not necessary to observe the system for these conclusions to hold. If we do not observe the system, it then has to be described by a density operator, whose time evolution follows the appropriate Bloch equations. This time evolution can in principle be decomposed into individual trajectories each of which consists of no{jum p evolutions interrupted by spontaneous em issions [23]. For each of these trajectories our considerations above hold and therefore also hold for the incoherent sum of these trajectories which make up the ensemble. Therefore our error correction code is not restricted to a particular m easurem ent scheme such as for example the detection and reconstruction scheme discussed in [25], where it is necessary to detect individual quantum jumps. Nevertheless such a detection of individual jum ps would im prove the perform ance of our code, as that would exclude the contribution of multiple quantum jumps with which our code cannot cope. This would enhance the importance of the conditional time evolution as a error source com pared to other sources and it is here where our code is superior to previous codes.

III.CORRECTING SPONTANEOUS EM ISSION

The discussion of the last section shows that it is of some interest to construct a quantum error correcting code that corrects errors due to the conditional time evolution to all orders. This is possible, and in the following we present such a quantum error correcting code.

The following code was constructed starting from the code (1)-(2). State jDi is encoded as

 $p_L i = p0001111i + p1101000i p0010110i p1110001i + p1010100i + p0110011i + p1001101i + p10101010i ; (7)$

while state jli is encoded as

jL_i= jlll0000i j00010111i+ j1101001i jl0001110i p0101011i+ jl001100i+ jl0110010i p1010101i: (8)

The state eq. (7) encoding the logical 0 was obtained in the following way. We started with state eq. (1) and for each word, e.g. jl1100i we constructed the bitwise inverse, i.e. j00011i. We concatenated the two words where the second one is taken in reverse bit order to obtain jl110011000i. This method, applied to all words in eq. (1), already yields a possible code. However, it is

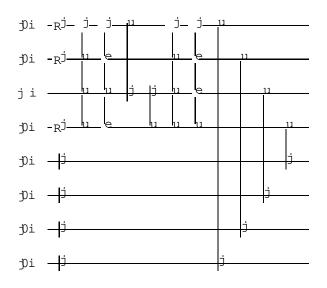

Figure 1: The encoding network: R describes a one bit rotation which takes (j)i ! (j)i + jii) = 2 and jii ! (j)i = jii) = 2. An encircled cross denotes a NOT operation while a dot denotes a control bit. For a led circle the operation is carried out if the control bit is 1; for an empty circle the operation is carried out if the control bit is 0. A circle with a represents multiplication with phase exp(i).Qubit 3 is in the state j i that we wish to encode, while all other qubits are initially in their ground state j0i.

possible to shorten the code by removing bits 5 and 6 from every word. This then yields eq. (7) and analogously eq. (8). Subsequently a computer search was m ade for potentially shorter codes; this revealed no such codes, so we conclude that n = 8 qubits is the m inim um number required for the task of correcting one general error while errors due to the conditional time evolution are corrected perfectly. In the following we present som e interesting properties of the code and dem onstrate that it indeed has the claim ed error correction properties. How ever, this code di ers in m any ways from previously proposed codes. First of all, it violates the conditions given for quantum error correcting codes in [11] thereby show ing that these conditions are overly restrictive. As these conditions were used to derive the inequality eq. (3), their violation indicates that there m ight exist codes that require less qubits than expected from eq. (3). How ever, we did not yet succeed to construct a code that violates eq. (3). One should also realize that the codew ords in the code eqs. (7)-(8) do not form a linear code as this would in ply that j00000001 is a codew ord which in turn would render in possible the task of constructing a code with codewords of equal excitation. Nevertheless, the codewords of \mathcal{D}_L i form a coset of a linear code. The coset leader is 1000011111i. This contrasts slightly with other codes such as those presented in $[5,8\{10]$. The codew ords of the code (1)-(2) for example form a linear code. G iven

the initial state j i = (j)i + jli, we obtain the code eqs. (7)-(8) using the network given in g. 1. To correct the error that m ay have appeared we rst apply the encoder in the reverse direction (right to left). A fter the application of the decoder, the third qubit contains inform ation about the encoded state while the remaining 7 qubits contain the error syndrom e, from which one can infer the type and location of the error. W e m easure the qubits of the error syndrom e and apply, according to the result of our m easurem ent, a suitable unitary operation on qubit 3. W e assume that after the m easurem ent all the other qubits are reset to their ground state (j) so that, in principle, we can re-encode the state again using the sam e qubits.

Error	E rror syndrom e	State of qubit 3
None	0000000	jDi+ jli
P ₁	1000000	jDi+ jli

A ₄	1001000	jDi jli

Table 1: O ne obtains an error syndrom e, ie. the state of all qubits except qubit 3, depending on the error that occurred and the place in which it occurred. P_i indicates a sign change of the upper level of qubit i, A_i an am plitude error which is given by the transform ation jDi \$ jli. The product of both applied to the sam e qubit gives the third kind of error. Note that the error syndrom e is not able to distinguish between P_i and P_{9-i} which leads to global phases in some of the corrected states. This table does not take into account that before and after the error a conditional tim e evolution takes place.

In table 1 we give all possible outcom es of the m easurem ent and the corresponding state of the third qubit. The necessary unitary transform ation that has to be applied onto the third qubit is then obvious. Careful inspection of table 1 reveals that this error correction scheme has,

for som e errors, a slightly di erent e ect than expected. Take for example a phase errors P_1 on bit 1 and compare with the e ect of a phase error P $_8$ on bit 8. W e observe that they both lead to the sam e error syndrom e but that the resulting state di ers by a global phase 1. Therefore it is not possible to correct both states in such a way that they go over to the initial state. A fler the correction they dierby a global phase 1. But this also show s that the dimension of the space H code spanned by the code together with all states that result from it by single errors is 2 21 and not as expected from eq. (3) 2 25. The latter num ber results from the considerations of E kert and M acchiavello [11] who have presented a set of conditions that have to be satis ed by any quantum error correction code. The violation of these conditions by the code eq. (7)-(8) leads to these di erent predictions for the dim ension of H code. M ore general conditions can be derived and it can be checked easily that our code satis es these conditions [13,26] while it violates the conditions given in [11].

So far we have shown that our code can indeed correct a general single error without taking into account the conditional time evolution due to spontaneous emission. Now we show that our code is able to correct errors due to the conditional time evolution perfectly, ie. to all orders. For our code given in eqs. (7)-(8) the conditional time evolution under the assumption that no spontaneous emission has taken place is generated by the e ective H amilton operator

$$H_{eff} = \bigcup_{i=1}^{X^8} ih \bigcup_{11}^{(i)} :$$
 (9)

If the code undergoes a conditional time evolution before it experiences an error like e.g. a spontaneous emission, it is obvious that the code eqs. (7)-(8) will work properly, as it is invariant under the conditional time evolution exp($iH_{eff}t=h$). However, it is not so obvious that the code corrects general single errors that occur before or in between the conditional time evolution. As we do not know the time at which the general error occurs, this situation will alm ost certainly occur and has to be examined. If the error was a phase error, then no problem will occur, as this error does not change the excitation of the state. However, for am plitude errors or a com bination of am plitude and phase errors we have to investigate the code m ore closely. The problem is that, for exam ple after an am plitude error in the rst qubit, we obtain

Now the code words have a di erent degree of excitation so that their relative weights will change during the subsequent conditional time evolution. However, for $j_L i = \mathcal{D}_L i + \mathcal{J}_L i$ we have the relations $j_L i = \mathcal{D}_L i + \mathcal{J}_L i$

$$e^{iH_{eff}t=h}A_{i}j_{L}i=\frac{1}{2}e^{3t}(1+e^{2t})A_{i} (1 e^{2t})A_{i}P_{i}j_{L}i (11)$$

and

$$e^{iH_{eff}t=h}A_{i}P_{i}j_{L}i = \frac{1}{2}e^{3t} (1 e^{2t})A_{i} + (1 + e^{2t})A_{i}P_{i} j_{L}i : (12)$$

Eq. (11) shows that after an amplitude error A_i on the ith qubit, the conditional time evolution transforms the state into a superposition of a state without conditional time evolution after this amplitude error, and a state without conditional time evolution obtained after a combined amplitude and phase error A_iP_i on the ith qubit. Inspecting table 1 we see that both errors A_i and A_iP_i lead to a dimensional time or the other error, A_i or A_iP_i , which can then be corrected. Therefore the code (7)–(8) corrects properly even if the error is followed by a conditional time evolution.

IV . C O N C LU S IO N S

W e conclude that the code presented here is able to correct a single general error and in addition errors due to the conditional time evolution to arbitrary order. It is the rst code proposed so far that can correct a general errors to rst order and a special kind of errors to all orders. This is an interesting result as it shows that it is possible to correct special kinds of errors to all orders. A s som e errors are more frequent than others it would be in our interest to correct those errors to higher order than less frequently occurring errors. We have adapted our code to errors due to the conditional time evolution between spontaneous em issions. O ther applications will require di erent adaptions. The code presented here (sim ilar to the one given in [5]) violates the conditions for quantum codes given in [11] which shows that these conditions are overly restrictive, as they exclude codes like the one presented here that m ap di erent errors onto the sam e error syndrom es. This can lead to the construction of shorter quantum error correction codes than expected from the quantum sphere packing bound as derived in [11]. These results may become important in dierent elds such as quantum computation, the distribution of entangled particles and in quantum cryptography [27{30].
